Dispensatory of the U.S.A.

PREFACE TO THE EIGHTEENTH EDITION.

THE first edition of the United States Dispensatory appeared in 1833, the present edition being the eighteenth; a little less than four years has, therefore, on the average elapsed between the successive revisions of the work. It is now five years since the publication of the seventeenth edition, and at no period in the history of the world has there been so much activity in the field of Materia Medica and Therapeutics as during these five years. The time has, therefore, been for many months fully ripe for the appearance of a new edition of the United States Dispensatory, the urgency of the need being emphasized by the extraordinary discoveries in the field of synthetic remedies, but the work was delayed at least a year, waiting for the publication of the British Pharmacopœia, comments upon this standard having always been a feature of the Dispensatory.

The most laborious work of the editors has been in the consideration of synthetic remedies, and, excepting in regard to the British Pharmacopœia, the greatest amount of change will be found in SECTION II., PART II., of the present volume, which treats of new drugs, nearly two hundred articles having been written for this portion of the book. The text of the work has everywhere been gone over very carefully for the purpose of condensation. Much matter rendered effete by the lapse of time has been altogether elided or greatly condensed, especially in the second part of the book. The botany has been thoroughly revised by Professor Henry Kraemer, of the Philadelphia College of Pharmacy, whose knowledge and reputation must bring increased authority to this very important division. Professor Rusby has revised his article on cinchona, so that it retains its original freshness, and remains, we believe, the best consideration of the subject extant.

No material change has taken place either in the nomenclature, in the use of weights and measures, molecular formulæ, or atomic weights since the last revision. The feature of the double indices has been preserved, and the preparation of both is the work of Dr. Horatio C. Wood, Jr.

The partitioning of the labor of the preparation of the book among the editors has been as heretofore. The typographical arrangement of the work has undergone no alteration. As in the last edition, when a remedy is official in both the United States and the British Pharmacopœias under one name, the letters "U. S., Br." follow the Latin title; but when drugs or preparations substantially the same are official under different names, the Br. is put in parentheses—thus, "U. S. (Br.)"—following the Latin title, whilst the British name is given in black letters first among the synonymes.

Finally, the editors lay before their professional brethren the eighteenth edition of the United States Dispensatory, knowing that no labor has been spared to make it worthy of its predecessors, and trusting that it will receive from the professions of Medicine and Pharmacy throughout the world that generous appreciation which has in the past been to the editors at once the highest reward for their labors and the strongest incentive to continuous effort.

PREFACE TO THE FIRST EDITION.

THE objects of a Dispensatory are to present an account of medicinal substances in the state in which they are brought into the shops, and to teach the modes in which they are prepared for use. The importance of these objects, and the general value and even necessity of a work of this nature, will not be disputed. It may, however, be a question, how far the wants of the medical and pharmaceutical community in this country are supplied by the Dispensatories already in circulation; and whether such a deficiency exists as to justify the offer of a new one to the public attention. The great merits of the works severally entitled "The Edinburgh New Dispensatory" and "The London Dispensatory," the former edited by the late Andrew Duncan, M.D., the latter by Anthony Todd Thomson, M.D., are well known wherever the English language is spoken. Founded, as they both are, upon the excellent basis laid by Lewis, they are nevertheless entitled, from the great addition of valuable materials, and the distinctive character exhibited in the arrangement of these materials, to be considered as original works; while the style in which they have been executed speaks strongly in favor of the skill and industry of their authors. But they were calculated especially for the sphere of Great Britain, and are too deficient in all that relates exclusively to this country, to admit of being received as standards here. In the history of our commerce in drugs, and of the nature, growth, and collection of our indigenous medical plants; in the chemical operations of our extensive laboratories; and in the modes of preparing, dispensing, and applying medicines, which have gradually grown into use among us; there is much that is peculiar, a knowledge of which is not to be gained from foreign books, and is yet necessary to the character of an accomplished American pharmaceutist. We have, moreover, a National Pharmacopœia, which requires an explanatory commentary, in order that its precepts may be fully appreciated, and advantageously put into practice. On these accounts, it is desirable that there should be a Dispensatory of the United States, which, while it embraces whatever is useful in European pharmacy, may accurately represent the art as it exists in this country, and give instruction adapted to our peculiar wants. It appears due to our national character that such a work should be in good faith an American work, newly prepared in all its parts, and not a mere edition of one of the European Dispensatories, with here and there additions and alterations, which, though they may be useful in themselves, cannot be made to harmonize with the other materials so as to give to the whole an appearance of unity, and certainly would not justify the assumption of a new national title for the book. Whether, in the Dispensatories which have been published in the United States, these requisites have been satisfactorily fulfilled, it rests with the public to determine. That valuable treatises on Materia Medica and Pharmacy have been issued in this country, no candid person, acquainted with our medical literature, will be disposed to deny. In offering a new work to the medical and pharmaceutical professions, the authors do not wish to be considered as undervaluing the labors of their predecessors. They simply conceive that the field has not been so fully occupied as to exclude all competition. The Pharmacy of continental Europe is ground which has been almost untouched; and much information in relation to the natural history, commerce, and management of our own drugs, has lain ungathered in the possession of individuals, or scattered in separate treatises and periodicals not generally known and read. Since the publication of the last edition of our National Pharmacopœia, no general explana-

tion of its processes has appeared, though required in justice both to that work and to the public. The hope of being able to supply these deficiencies may, perhaps, be considered a sufficient justification for the present undertaking.

The Pharmacopœia of the United States has been adopted as the basis of this Dispensatory. It is followed both in its general division of medicines, and in its alphabetical arrangement of them under each division. Precedence is, in every instance, given to the names which it recognizes, while the explanations by which it fixes the significance of these names are inserted in immediate connection with the titles to which they severally belong. Every article which it designates is more or less fully described; and all its processes, after being literally copied, are commented on and explained wherever comment and explanation appeared necessary. Nothing, in fine, has been omitted, which, in the estimation of the authors, could serve to illustrate its meaning, or promote the ends which it was intended to subserve. This course of proceeding appeared to be due to the national character of the Pharmacopœia, and to the important object of establishing, as far as possible, throughout the United States, uniformity, both in the nomenclature and preparation of medicines. In one particular, convenience required that the plan of the Pharmacopœia should be departed from. The medicines belonging to the department of MATERIA MEDICA, instead of being arranged in two divisions corresponding with the *Primary and Secondary Catalogues* of that work, have been treated of indiscriminately in alphabetical succession; and the place which they respectively hold in the Pharmacopœia is indicated by the employment of the term *Secondary*, in connection with the name of each of the medicines included in the latter catalogue.

But, though precedence has thus been given to the Pharmacopœia of the United States, those of Great Britain have not been neglected. The nomenclature adopted by the different British Colleges, and their formulas for the preparation of medicines, have been so extensively followed throughout the United States, that a work intended to represent the present state of pharmacy in this country would be imperfect without them; and the fact that the writings of British physicians and surgeons, in which their own official terms and preparations are exclusively employed and referred to, have an extensive circulation among us, renders some commentary necessary in order to prevent serious mistakes. The Pharmacopœias of London, Edinburgh, and Dublin have, therefore, been incorporated, in all their essential parts, into the present work. Their official titles are uniformly given, always in subordination to those of the United States Pharmacopœia, when they express the same object; but in chief, when, as often happens, no corresponding medicine or preparation is recognized by our national standard. In the latter case, if different names are applied by different British Colleges to the same object, that one is generally preferred which is most in accordance with our own system of nomenclature, and the others are given as synonymes. The medicines directed by the British Colleges are all described, and their processes either copied at length, or so far explained as to be intelligible in all essential particulars.

Besides the medicinal substances recognized as official by the Pharmacopœias alluded to, some others have been described, which, either from the lingering remains of former reputation, from recent reports in their favor, or from their important relation to medicines in general use, appear to have claims upon the attention of the physician and apothecary. Opportunity has, moreover, been taken to introduce incidentally brief accounts of substances used in other countries or in former times, and occasionally noticed in medical books; and, that the reader may be able to refer to them when desirous of information, their names have been placed with those of the standard remedies in the Index.

In the description of each medicine, if derived immediately from the animal, vegetable, or mineral kingdom, the attention of the authors has been directed to its natural history, the place of its growth or production, the method of collecting and preparing it for market, its com-

mercial history, the state in which it reaches us, its sensible properties, its chemical composition and relations, the changes which it undergoes by time and exposure, its accidental or fraudulent adulterations, its medical properties and application, its economical uses, and the pharmaceutical treatment to which it is subjected. If a chemical preparation, the mode and principles of its manufacture are indicated in addition to the other particulars. If a poison, and likely to be accidentally taken, or purposely employed as such, its peculiar toxicological effects, together with the mode of counteracting them, are indicated; and the best means of detecting its presence by reagents are explained.

The authors have followed the example of Dr. A. T. Thomson, in giving botanical descriptions of the plants from which the medicines treated of are derived. In relation to all indigenous medicinal plants, and those naturalized or cultivated in this country, the advantages of such descriptions are obvious. The physician may often be placed in situations, in which it may be highly important that he should be able to recognize the vegetable which yields a particular medicine; and the apothecary is constantly liable to imposition from the collectors of herbs, unless possessed of the means of distinguishing, by infallible marks, the various products presented to him. A knowledge of foreign medicinal plants, though of less importance, will be found useful in various ways, independently of the gratification afforded by the indulgence of a liberal curiosity in relation to objects so closely connected with our daily pursuits. The introduction of these botanical notices into a Dispensatory appears to be peculiarly appropriate; as they are to be considered rather as objects for occasional reference than for regular study or continuous perusal, and therefore coincide with the general design of the work, which is to collect into a convenient form for consultation all that is practically important in relation to medicines. The authors have endeavored to preserve a due proportion between the minuteness of the descriptions, and their value as means of information to the student; and, in pursuance of this plan, have generally dwelt more at length upon our native plants than upon those of foreign growth; but, in all instances in which they have deemed a botanical description necessary, they have taken care to include in it the essential scientific character of the genus and species, with a reference to the position of the plant in the artificial and natural systems of classification; so that a person acquainted with the elements of botany may be able to recognize it when it comes under his observation.

In preparing the Dispensatory, the authors have consulted, in addition to many of the older works of authority, the greater number of the treatises and dissertations which have recently appeared upon the various subjects connected with Pharmacy, and especially those of the French writers, who stand at present at the head of this department of medical science. They have also endeavored to collect such detached facts, scattered through the various scientific, medical, and pharmaceutical journals, as they conceive to be important in themselves, and applicable to the subjects under consideration; and have had frequent recourse to the reports of travellers in relation to the natural and commercial history of foreign drugs. The occasional references in the body of the work will indicate the sources from which they have most largely drawn, and the authorities upon which they have most relied. In relation to our own commerce in drugs, and to the operations of our chemical laboratories, they are indebted for information chiefly to the kindness of gentlemen engaged in these branches of business, who have always evinced, in answering their numerous inquiries, a promptitude and politeness which merit their warm thanks, and which they are pleased to have this opportunity of acknowledging.*

* The authors deem it proper to state that they are peculiarly indebted for assistance to Mr. Daniel B. Smith, president of the Philadelphia College of Pharmacy, to whom, besides much important information in relation to the various branches of the apothecary's business, they owe the prefatory remarks on Pharmacy, which are placed at the commencement of the second part of the work, and the several articles, in the Materia Medica, upon *Leeches*, *Carbonate of Magnesia*, and *Sulphate of Magnesia*.

It has not been deemed necessary to follow the example of the British [illegible] by inserting into the work a treatise upon chemistry, under the name of 'Elements of [illegible]'. Such a treatise must necessarily be very meagre and imperfect, and, as systems of [illegible] can be had of many [illegible] [illegible] [illegible]

PREFACE TO THE FIFTEENTH EDITION.

JUST fifty years have gone by since Dr. Geo. B. Wood penned the preface to the first edition of the United States Dispensatory. Written from a sense of duty, and in the earnest belief that to obtain the acceptance of the newly born United States Pharmacopœia by the American professions of Medicine and Pharmacy a standard commentary was necessary, the book achieved a success which, to its authors, was as unexpected as it was gratifying. During the half-century that has elapsed, the work has passed through fourteen editions; revolutions have swept over science, the fate that awaits all men has come to the authors; and yet, with a steadiness that is unrivalled in medical literature, the United States Dispensatory has maintained its supremacy, until the copies of it which have been sold are to be numbered by the hundreds of thousands, and wherever the English language leads, it follows. Even in the last years, when it was sorely in need of revision, the demand for it has not perceptibly diminished. Such success as this must depend upon extraordinary qualities in the book. Thoroughness, accuracy, and completeness undoubtedly have had much to do with the result, but we conceive that the pre-eminent usefulness of the Dispensatory has rested largely upon the peculiar ability of its authors to perceive what facts are useful and essential to a subject, and upon their judgment and skill in utilizing and setting forth these facts.

In attempting the revision of a book which has become so necessary to the American professions, the editors have fully comprehended the difficulties and the importance of their task. They all have had the experience and the peculiar growth in the power of appreciating the proportionate fitness and importance of facts, which come with successive years of active life as teachers. One of them has had the good fortune to have worked through the revisions of three editions under the rigid discipline of Dr. Geo. B. Wood, and to have become thoroughly familiar with his methods, not only of work, but also of thought, and with the principles which in his mind were essential to the building up of the Dispensatory. The editors come, therefore, to the work not without some especial preparation. Moreover, for the first time in the history of the volume, the original plan of Dr. Geo. B. Wood of having three editors, one for each branch of the subject-matter, has been realized.

It is evident that in the revision of a book with a history like that of the present the changes should be as few as possible. The editors have constantly borne this principle in mind, but circumstances have forced them, whilst strenuously endeavoring to retain the characteristics and essential features of the work, in great part to remodel it. The alteration in the plan of the Pharmacopœia has necessitated a parallel change in the Dispensatory. The first and second parts have therefore been alphabetically collated and formed into PART I. of the present edition. PART III. of former editions has been kept isolated as PART II.; because were it not for the great gain of space achieved by the use of the small type, two volumes would be required to contain the material now compressed between a single pair of covers. The amount of new matter added at this revision may be judged of from the fact that whilst in the index of the fourteenth edition there were about eleven thousand references, in the present index there are more than sixteen thousand titles, including in these, however, German

and French synonymes, never before indexed. PART III. of the present volume contains a revision of the Appendix of former editions, with various miscellaneous new matter.

When the fourteenth edition of the Dispensatory was published, Dr. Geo. B. Wood was nearly eighty years of age, and, although he sympathized with the movement which has resulted in putting therapeutics upon the firm foundation of physiological rationalism, he could not fully apprehend the changes which had occurred in therapeutical methods during the previous decade. Consequently, in most of the more important articles the sections treating of Medical Properties and Uses have had to be rewritten. The revision of these sections, as well as of the Botany and Vegetable Materia Medica, has fallen to the senior editor, Prof. H. C. Wood.

The progress of the last decade has necessitated important changes in those sections of the Dispensatory which treat of Pharmaceutical Chemistry, whilst the Pharmacy of the present edition is almost entirely new. This part of the revision has been performed by Prof. Jos. P. Remington, by whose calculations the official formulas have been adapted to the use of those pharmacists who prefer the system of measuring liquids. The alternative formulas *have* [illegible] transition stage, caused by the adoption of the principle of *parts by weight*.

Dr. Franklin Bache died in 1864, at the time when the agitation was commencing in chemical science which has ended in the received nomenclature and theory. Since the death of the chemical author the portions of the Dispensatory especially within his province have had no proper revision and adaptation to the needs of the day. All of the Theoretical Chemistry of [illegible] has been allotted to Prof. S. P. Sadtler; and we believe that in all points the Dispensatory now represents the latest solid achievements of chemical science.

[illegible] of American Mineral Springs, as far as they have been published, with a number of analyses of European Springs of note; and to the [illegible] minor exceptions, original; and the very accurate representa[illegible] will, we believe, be of service to students of structural characters.

Pages XI-XII missing

GLOSSARY.

In the following Glossary will be found short definitions of many of the terms employed in the Dispensatory to designate the medical properties of the remedies: most of the words are commonly employed as nouns, and sometimes as adjectives.

Absorbents.—Drugs used to produce absorption of exudates or diseased tissues.
Abstergents.—Detergents.
Alteratives.—Medicines used to so modify nutrition as to overcome morbid processes.
Anæsthetics.—Medicines used to produce anæsthesia or unconsciousness.
Analeptics.—Restorative medicines, or food.
Analgesics.—Medicines used to allay pain.
Anaphrodisiacs.—Medicines used to allay sexual feeling.
Anodynes.—Medicines used to allay pain.
Antacids.—Medicines used to neutralize acid in the stomach and intestines.
Anthelmintics.—Medicines used to destroy intestinal worms.
Antiarthritics.—Medicines used for the relief of gout.
Antihydropics.—Medicines used for the relief of dropsy.
Antilithics.—Medicines used for the relief of calculous affections.
Antiperiodics.—Medicines used for the relief of malarial fevers.
Antipyretics.—Medicines used for the reduction of bodily temperature in fevers.
Antiseptics.—Substances which have the power of preventing putrefaction.
Antispasmodics.—Medicines used for the relief of nervous irritability and minor spasms.
Antisyphilitics.—Medicines used for the relief of syphilis.
Antizymotics.—Substances which have the power of killing disease-germs.
Aperients.—Mild purgatives.
Aphrodisiacs.—Substances used to increase sexual power or excitement.
Aromatics.—Medicines characterized by a fragrant or spicy taste and odor, and stimulant to the gastro-intestinal mucous membrane.
Aromatic Bitters.—Medicines which unite the properties of the aromatics and the simple bitters.
Astringents.—Medicines which have the power of influencing vital contractility and thereby condensing tissues.
Bitters—Simple.—Medicines which have a bitter taste and have the power of stimulating the gastro-intestinal mucous membrane, without affecting the general system.
Blisters.—Medicines which when locally applied cause inflammatory exudation of serum from the skin, and are used as revulsants.
Calefacients.—Medicines used externally to cause a sense of warmth.
Cardiac Depressants.—Medicines used to lower the heart's action.
Cardiac Stimulants.—Medicines used to increase the heart's action.
Carminatives.—Medicines containing a volatile oil used to excite intestinal peristalsis and provoke an expulsion of flatus.
Cathartics.—Purgatives.
Caustics.—Medicines used to destroy living tissues.
Cholagogues.—Medicines which provoke a flow of bile.
Constringents.—Astringents.
Convulsants.—Medicines which cause convulsions.
Correctives.—Medicines used to correct or render more pleasant the action of other remedies, especially purgatives.
Corrigents.—Correctives.
Demulcents.—Mucilaginous principles which are used in solution to soothe and protect irritated mucous membranes or other tissues.
Deobstruents.—(Term obsolete and not very definite.) Medicines which overcome obstruction; aperients.
Deodorants.—Substances which destroy or hide foul odors.

DEPILATORIES.—Substances used to remove hair.
DEPRESSANTS.—Sedatives.
DEPRESSO-MOTORS.—Medicines which lessen motor activity.
DEPURANTS.—Medicines which act upon the emunctories so as to cause excretion and thereby purify the system.
DETERGENTS.—Medicines which cleanse wounds, ulcers, etc.
DIAPHORETICS.—Medicines which produce sweating.
DIGESTANTS.—Ferments and acids which have the power of aiding in the solution of food.
DILUENTS.—Medicines which dilute secretions and excretions.
DISINFECTANTS.—Substances which have the power of destroying disease-germs or the noxious properties of decaying organic matter.
DIURETICS.—Medicines which increase the secretion of urine.
DRASTICS.—Purgatives which cause much irritation.
ECBOLICS.—Medicines which produce abortion.
ECCOPROTICS, or ECTOPROTICS.—Laxatives.
EMETICS.—Medicines which cause vomiting.
EMMENAGOGUES.—Medicines which stimulate menstruation.
EMOLLIENTS.—Substances used to mechanically soften and protect tissues.
EPISPASTICS.—Blisters.
ERRHINES.—Medicines which increase the nasal secretions.
ESCHAROTICS.—Caustics.
EVACUANTS.—Medicines which evacuate: chiefly applied to purgatives.
EXCITANTS.—Stimulants.
EXCITO-MOTORS.—Medicines which increase motor activity.
EXPECTORANTS.—Medicines which act upon the pulmonic mucous membrane and increase or alter its secretions.
FEBRIFUGES.—Medicines which dissipate fever.
GALACTAGOGUES.—Medicines which increase the secretion of milk.
HÆMOSTATICS.—Medicines which arrest hemorrhages.
HYDRAGOGUES.—Purgatives which cause large watery discharges.
HYPNOTICS.—Medicines which cause sleep.
LAXATIVES.—Mild purgatives.
LOCAL ANÆSTHETICS.—Medicines which when applied locally destroy sensation.
MYDRIATICS.—Medicines which cause *mydriasis*, or dilatation of the pupil.
MYOTICS.—Medicines which cause *myosis*, or contraction of the pupil.
NARCOTICS.—Powerful anodyne hypnotics.
NEUROTICS.—Medicines which act upon the nervous system.
NUTRIANTS.—Medicines which modify the nutritive processes.
NUTRIENTS.—Substances which nourish.
OXYTOCICS.—Medicines which stimulate uterine contractions.
PERISTALTICS.—Medicines which increase peristalsis.
PROPHYLACTICS.—Medicines which prevent the taking or development of disease.
PROTECTIVES.—Medicines which protect a part when applied to it.
PTYALAGOGUES.—Sialagogues.
PURGATIVES.—Medicines which produce copious discharges from the bowels.
REFRIGERANTS.—Medicines which lessen the bodily temperature.
REVULSANTS.—Medicines which by causing irritation draw nervous force and blood from a distant diseased part.
RUBEFACIENTS.—Medicines which cause irritation and redness, and are used as revulsants.
SEDATIVES.—Medicines which lower functional activity.
SIALAGOGUES.—Medicines which excite the salivary glands to secretion.
SOMNIFACIENTS.—Soporifics.
SOPORIFICS.—Medicines which cause sleep.
SORBEFACIENTS.—Medicines which cause absorption.
SPECIFICS.—Medicines which have a direct curative influence on certain individual diseases.
STIMULANTS.—Medicines which increase functional activity.
STOMACHICS.—Stimulants to the stomach.
STYPTICS.—Hæmostatics.
SUDORIFICS.—Medicines which produce sweating.
TÆNICIDES.—Medicines which kill the tape-worm.
TONICS.—Medicines which permanently increase the systemic tone by stimulating nutrition.
VERMICIDES.—Medicines which kill intestinal worms.
VERMIFUGES.—Medicines which cause the expulsion of intestinal worms.
VESICATORIES.—Blisters.

THE DISPENSATORY

OF

THE UNITED STATES.

PART I.

THE United States Dispensatory may very properly be considered as a commentary upon the United States and British Pharmacopœias, whilst such preparations of the German Pharmacopœia and French Codex as are used generally in the United States are also commented upon. As was explained in the fifteenth edition, the changes in the arrangement of the 1880 edition of the United States Pharmacopœia necessitated corresponding alterations in the United States Dispensatory. PART I. of the present volume contains the discussion of all the remedies recognized by either of the two Pharmacopœias used by English-speaking people. In PART II. the National Formulary is introduced; this is designated as Section I., whilst non-official drugs and preparations are treated, as heretofore, by themselves; they are classed now in Section II., and are printed in smaller type than that used for official substances, it being deemed judicious to adhere to a plan which has given so much satisfaction in the previous editions. In PART III. are considered the Tests and Test-Solutions of the two Pharmacopœias, Weights and Measures, the Art of Prescribing Medicines, and cognate miscellaneous matters.

There can be no question as to the superiority of the alphabetical arrangement of drugs in a book of reference of an encyclopedic character. Their scientific classification belongs to works which treat of them rather in their relations than their essential properties; and different systems have been adopted, according to the set of relations towards which the mind of the author has been especially directed. Thus, the naturalist classifies them according to the affinities of the several objects in nature from which they are derived; the chemist, according to their composition; the practitioner of medicine, according to their effects upon the system in a state of health and disease.

ABSINTHIUM. U.S. Absinthium. [Wormwood.]

(AB-SĬN'THI-ŬM.)

"The leaves and tops of Artemisia Absinthium, Linné (nat. ord. Compositæ)." *U. S.*

Wormwood; Absinthe commune, Grande Absinthe, Armoise amère, *Fr.;* Gemeiner Wermuth, *G.;* Assenzio, *It.;* Artemisio Axenjo, *Sp.*

Gen. Ch. *Receptacle* sub-villous, or nearly naked. *Seed-down* none. *Calyx* imbricate, with roundish converging scales. *Corollas of the ray* none. *Willd.*

Several species of Artemisia have enjoyed some reputation as medicines. The leaves of *A. abrotanum*, or *southernwood*, are reported by Craveri to contain a crystallizable alkaloid, *abrotine;* they have a fragrant odor, and a warm, bitter, nauseous taste, and were formerly employed as a tonic, deobstruent, and anthelmintic. Similar virtues have been ascribed to *A. santonica*. *A. pontica* has been occasionally substituted for common wormwood, but is weaker. *A. vulgaris*, or *mugwort*, formerly enjoyed considerable reputation as an emmenagogue, and has been used in Germany in *epilepsy*. Along with asafetida it is also sometimes given in *chorea* and in *amenorrhœa*. *A. ludoviciana*, a native of the southwestern regions of the United States, is thought, when applied to the head in the state of infusion, to favor the growth of the hair.

(Maisch, *A. J. P.*, 1872, p. 106.) In China, *moxa* is said to be prepared from the leaves of *A. chinensis* and *A. indica*. The medicine known in Europe by the name of wormseed is the product of different species.

Artemisia absinthium. Willd. *Sp. Plant.* iii. 1844; Woodv. *Med. Bot.* p. 54, t. 22. Wormwood is a perennial plant, with branching, round, and striated or furrowed stems, which rise two or three feet in height, and are panicled at their summit. The lower portion of the stem lives several years, and annually sends up herbaceous shoots, which perish in the winter. The radical leaves are triply pinnatifid, with lanceolate, obtuse, dentate divisions; those of the stem, doubly or simply pinnatifid, with lanceolate, somewhat acute divisions; the floral leaves are lanceolate; all are hoary. The flowers are of a brownish-yellow color, hemispherical, pedicelled, nodding, and in erect racemes. The florets of the disk are numerous, those of the ray few. The plant is a native of Europe, where it is also cultivated. It is among our garden herbs, and has been naturalized in the mountainous districts of New England. The leaves and flowering summits are employed; the larger parts of the stalk being rejected. They should be gathered in July or August, during flowering. They long preserve their sensible properties when dried.

"Leaves about 5 Cm. long, hoary, silky-pubescent, petiolate, roundish-triangular in outline; pinnately two- or three-cleft, with the segments lanceolate, the terminal one spatulate; bracts three-cleft or entire; heads numerous, about 3 Mm. long, subglobose, with numerous small, pale-yellow florets, all tubular and without pappus; odor aromatic; taste persistently bitter." *U.S.*

Wormwood yields by distillation a volatile oil (*oleum absinthii*), usually dark green, sometimes yellow or brownish, having a strong odor of the plant, an acrid peculiar taste, and the sp. gr. 0·925 to 0·950. It is sometimes adulterated with alcohol, oil of turpentine, etc., which lessen its specific gravity. The oil is composed of a terpene boiling at 150° C., and *thujone* (*absinthol*), which has a specific gravity 0·926, composition $C_{10}H_{16}O$, boiling point of 200° C. (392° F.) to 205° C., and when heated with phosphorus pentasulphide or zinc chloride is split into *cymene* ($C_{10}H_{14}$) and a resinous substance. The portion of thujone which does not distil over at about 200° C. consists chiefly of the coloring principles *azulene* of Piesse and *cærulëin* of Gladstone (*Journ. Chem. Soc.*, Jan. 1874). The dried herb yields much more oil than the fresh. The other constituents, according to Braconnot, are a very bitter and an almost insipid nitrogenous matter, an excessively bitter resinous substance, chlorophyll, albumen, starch, saline matters, and lignin; malic and acetic acids are also said to be present. The cold infusion becomes olive-green and turbid on the addition of ferric chloride, indicating the probable existence of a little tannic acid. (*Pereira.*) The *absinthic acid* found by Braconnot is said to be succinic acid. Caventou obtained the bitter principle *absinthin* in an impure condition. (See *U. S. D.*, 14th ed., p. 5.) Dr. E. Luck prepared pure absinthin in 1851. (*A. J. P.*, xxiii. 358.) A. Kromayer (*Arch. Pharm.* (2), cviii. 129) considers absinthin an aldehyde, and assigns to it the formula $C_{40}H_{56}O_8 + H_2O$. He prepared it by exhausting the dry herb with hot water, evaporating the decoction, absorbing the bitter principle with animal charcoal, extracting with alcohol, partially purifying with lead acetate, precipitating with tannin, dissolving the precipitate in alcohol, mixing with lead oxide, treating the dry residue with alcohol, filtering, and evaporating to dryness. Duquesnel obtained absinthin in prismatic, odorless crystals of an intensely bitter taste. The old *salt of wormwood* (*sal absinthii*) was impure potassium carbonate, made from the ashes of the plant. E. Classen found potassium chloride in distinctly-formed cubic and octohedral crystals in extract of wormwood. (*Amer. Journ. of Science*, 1882, p. 323.)

Medical Properties and Uses. Wormwood was known to the ancients as a stomachic tonic, especially useful in gastric debility. It was also employed as an antiperiodic and as an anthelmintic. At present it is little used in regular practice on this side of the Atlantic. In dogs and rabbits from thirty to fifty drops (1·5–2·5 C.c.) of the volatile oil will cause trembling, stupor, hebetude, and it may be insensibility; one to two drachms (3·75–7·5 C.c.) of it, violent epileptiform convulsions, with involuntary evacuations, unconsciousness, and stertorous breathing, which may or may not end in death. (Marcé, *Bull. Thérap.*, Mai, 1864; Magnan, *L'Union Méd.*, Août, 1864; Amory, *Bost. Med. and Surg. Journ.*, March, 1868, p. 83.) In man the oil acts similarly; a half-ounce (15 C.c.) of it caused, in a male adult, insensibility, convulsions, foaming at the mouth, and a tendency to vomit; though the patient recovered under the use of emetics, with stimulants and demulcents. (*Lancet*, Dec. 6, 1862.) According to Dr. J. L. Corning, the volatile oil is a powerful local anæsthetic, and has some general analgesic properties, being useful when applied locally in *rheumatic pains* and especially valuable given in the form of a liqueur as a narcotic stimulant in *cerebral exhaustion*. Böhm and Kobert affirm that the oil escapes through the kidneys unchanged. The dose in substance is

from one to two scruples (1·3–2·6 Gm.); of the infusion (one ounce in a pint of boiling water), from one to two fluidounces (30–60 C.c.); of the oil, one to two drops.*

ACACIA. U. S. (Br.) Acacia. [Gum Arabic.]

(Ā-CĀ'CI-Ā.)

"A gummy exudation from Acacia Senegal, Willdenow (nat. ord. Leguminosæ)." *U. S.*
"A gummy exudation from the stem and branches of Acacia Senegal, Willd., and of other species of Acacia, Willd." *Br.*

Acaciæ Gummi, *Br.;* Gum Acacia; Gummi Arabicum, Gummi Mimosæ; Gomme Arabique, *Fr.;* Arabisches Gummi, *G.;* Gomma Arabica, *It.;* Goma Arabiga, *Sp.;* Samagh Arabee, *Arab.*

This genus is one of those into which the old genus Mimosa of Linnæus was divided by Willdenow. The name *Acacia* was employed by the ancient Greeks to designate the gum-tree of Egypt, and has been appropriately applied to the new genus in which that plant is included.

Gen. Ch. HERMAPHRODITE. *Calyx* five-toothed. *Corolla* five-cleft, or formed of five petals. *Stamens* 4–100. *Pistil* one. *Legume* bivalve. MALE. *Calyx* five-toothed. *Corolla* five-cleft, or formed of five petals. *Stamens* 4–100. *Willd.*

The most important of the gum-yielding Acacias are *A. vera* and the official *A. Senegal. A. vera* and *A. Arabica* were considered by Willdenow to be distinct species, but are now esteemed as one.

Acacia vera. Willd. *Sp. Plant.* iv. 1805; Hayne, *Darstel. und Beschreib.* x. 34. Syn. *A. Arabica.* Willd. *Sp. Plant.* iv. 1805; Hayne, *Darstel. und Beschreib.* x. 32; Carson, *Illust. of Med. Bot.* i. 31.—*Acacia Nilotica*, Delille, *Illust. Flor. de l'Égypte*, p. 79. This is a tree of middle size, with numerous scattered branches, of which the younger are much bent, and covered with a reddish-brown bark. The leaves are alternate and bipinnate, with two pairs of pinnæ, of which the lower are usually furnished with ten pairs of leaflets, the upper with eight. The leaflets are very small, oblong-linear, smooth, and supported upon very short footstalks. On the common petiole is a gland between each pair of pinnæ. Both the common and partial petiole are smooth in typical specimens of *A. vera*, but downy in the variety *A. arabica.* Two sharp spines, from a quarter to half an inch long, of the color of the smaller branches, and joined together at their base, are found at the insertion of each leaf. The flowers are yellow, inodorous, small, and collected in globular heads supported upon slender peduncles which rise from the axils of the leaves, in number from two to five together. The fruit is a smooth, flat, two-valved legume, divided, by contractions occurring at regular intervals, into several roundish portions, each containing one seed. This species flourishes in Southern Nubia, Egypt, and Senegal, and is probably scattered over the whole intervening portions of Africa; it is also abundant in Hindostan.

A. Senegal, Willdenow; *A. verek*, Guillemin and Perottet, *Flore de Sénégambie*, 1830, 246, B. & T., 1877. *Mimosa senegal*, L. This is a small tree with a grayish bark, the inner layers of which are strongly fibrous, bipinnate leaves, dense spikes of small yellow flowers longer than the leaves, and broad pods 3 to 4 inches long, containing 5 or 6 seeds. It rarely exceeds 20 feet in height, forms large forests in Western Africa, north of the river Senegal, and is abundant in Eastern Africa, Kordofan, and Southern Nubia. It is known by the natives as *Verek* or *Hashab.*

Besides the species above described, the following afford considerable quantities of gum:—*A. karroo* of the Cape of Good Hope, formerly considered by some as identical with *A. vera;* *A. gummifera*, seen by Broussonet in Morocco near Mogador; *A. ehrenbergiana*, a shrub six or eight feet high, named in honor of the German traveller Ehrenberg, who observed it in the

* *Absinthe.* Under this name, a *liqueur* is much used in France, consisting essentially of an alcoholic solution of oil of wormwood containing some alcoholic extract of angelica, anise, and marjoram. According to Baudrimont (Chevallier, *Dictionnaire des Falsifications*, 6me éd.) the *absinthe ordinaire* contains 47·66 per cent. of alcohol, the *demi-fine* 50 per cent., the *fine* 68 per cent, and the *absinthe suisse* 80·66 per cent. The preparation, if manipulated properly, possesses naturally a bright-green color, brought to an olive-green by slight addition of caramel-coloring, but artificial coloring is often resorted to, and indigo, turmeric, cupric acetate, and aniline green have been used to produce the proper shade. According to the French law of 1872, the oil and other concentrated preparations of absinthe can be sold only by pharmacists, and by them only on prescription. It has for some time been noticed that the effects of this liqueur differ essentially from those of pure alcoholic drinks, constituting a series of symptoms which has been designated as *absinthism.* A case recorded by M. Magnan, in which the patient, having habituated himself to the use of brandy, and afterwards substituted *absinthe*, gave an opportunity of comparing the effects of the two kinds of drink; it appears that the characteristic symptoms of the latter, taken in excess, are restlessness at night, with disturbing dreams, nausea and vomiting in the morning, with great trembling of the hands and tongue, vertigo, and a tendency to epileptiform convulsions, in which the patient loses consciousness, falls, bites his tongue, foams at the mouth, makes facial grimaces, throws about his limbs, etc., but from which he usually recovers. See also *A. J. P.*, 1889, p. 612.

deserts of Libya, Nubia, and Dongola; *A. seyal*, growing in the same region, and also in Upper Egypt and Senegambia; *A. adansonii* and *A. verek*, said to contribute a portion of the Senegal gum; and *A. tortilis*, which attains the height of sixty feet, and inhabits Arabia Felix, Nubia, Dongola, and the Libyan Desert. According to Schweinfurth, *A. stenocarpa* yields the brownish gum of the Soudan sometimes known as the "*taleh*" *gum*, whilst gum from Gedaref and from Southern Nubia is yielded by the *A. fistula*. Brownish or reddish gums are also yielded by *A. nilotica*, and probably by various undescribed species.* *A. decurrens* and *A. floribunda* yield gum in Australia. Gum is also yielded by various trees not belonging to the genus Acacia.

The gum-bearing Acacias are all thorny or prickly trees or shrubs, calculated by nature for a dry and sandy soil, and flourishing in deserts where few other trees will grow. We are told that camels, attached to the caravans, derive from them their chief sustenance in many parts of those desolate regions in which Africa abounds. In such localities, they have a stunted growth, and present a bare, withered, and uninviting aspect; but in favorable situations, as on the banks of rivers, they are often luxuriant and beautiful.

Their bark and unripe fruit contain tannic and gallic acids, and are sometimes used in tanning. An extract was formerly obtained from the immature pods of *A. arabica* and *A. vera*, by expression and inspissation. It was known to the ancients by the name of *acaciæ veræ succus*, and was highly praised by some of the Greek medical writers, but is at present little used. It is a solid, heavy, shining, reddish-brown substance, of a sweetish, acidulous, styptic taste, and soluble in water. Its virtues are probably those of a mild astringent. On the continent of Europe, a preparation is said to be substituted for it called *acacia nostras*, obtained by expression and inspissation from the unripe fruit of *Prunus spinosa*, or the wild plum-tree.

The gum of the Acacias exudes spontaneously from the bark, and hardens on exposure; but incisions are sometimes made in order to facilitate the exudation. The gum is said also to be found immediately under the bark, where it is sometimes collected in regular cavities. (*Journ. de Pharm.*, t. xxiv. p. 321.) It is probably produced by a process of degeneration from the cellulose, and is incapable of serving further in plant-growth.† It is stated by Jackson that, in Morocco, the greatest product is obtained in the driest and hottest weather, and from the most sickly trees. An elevated temperature appears to be essential; for in cooler climates, though the tree may flourish, it yields no gum. According to Ehrenberg, the varieties in the characters of the gum do not depend upon difference in the species of the plant. Thus, from the same tree it will exude frothy or thick, and clear or dark-colored, and will assume, upon hardening, different shapes and sizes; so that the pieces, when collected, require to be assorted before being delivered into commerce. Schweinfurth and other observers state, however, that the finest gum is obtained only from the *A. vera*, and perhaps one or two other species.

Commercial History and Varieties. The most common varieties of this drug are the *Turkey* or *Egyptian*, the *Barbary*, the *Senegal*, and the *India gum*.

1. Turkey Gum. (*Egyptian Gum.*) Gum arabic formerly entered commerce almost exclusively through Egypt, being collected in Upper Egypt, Nubia, Kordofan, Darfur, and other regions of the Upper Nile, and carried to Alexandria, from whence it passed directly into the world's commerce or entered the latter through Smyrna, Trieste, or some other Mediterranean entrepôt. At one time the more or less colored varieties were known as *gum gedda*, whilst the white and fine drug was known as *gum turic;* names derived from Jidda and Tor, Red Sea ports, through which the varieties were erroneously supposed to be respectively exported. More recently three chief commercial varieties of Turkish or Egyptian gums were recognized. *Hashabi* or *Kordofan gum*, the finest of these varieties, was collected in the country westward of the White Nile; at one time it constituted the bulk of the superior gum arabic of com-

* For further information in regard to gum-bearing trees of Northern Africa, see *P. J. Tr.*, Aug. 1873; *Compt.-Rendus*, t. lxxix. p. 1175.

† In the lower orders of life the inner cell contents or protoplasm is often set free by the rapid conversion of the cellulose wall into a substance soluble in water, and it is asserted that very frequently in the higher plants cells can be seen with one-half of their walls still cellulose, the other gum. According to Wigand, arabin is a result of a further change in bassorin, but Mr. F. von Höhnel (*Berichte*, 1888) believes that whilst tragacanth is formed out of the cell-wall, arabin is formed from the cell contents. According to the independent researches of Dr. Beijerinck and of Dr. Wiesner (*P. J. Tr.*, xvi. p. 284), the change of the cell-wall is provoked by a peculiar ferment. Kraus found that the formation of gum in *Acacia melanoxylon* takes place only in the bark and not in the wood, that it flows from the sieve-tubes and the cells of the soft bast, and he asserts that it is not a product of the degeneration of the cellulose, but a true cell-content passing out through unchanged cell-walls. (*P. J. Tr.*, 1886, p. 840.) For further information see Hofmeister, *Handbuch der physiolog. Botanik*, Bd. iv. p. 368, 1865; also Müller, *Sitzb. Akad. Wiss. Wien*, ii., Juni, 1875; Mercadante, *Gaz. Chim.; Ber. Chem. Gesell.*, 1876, p. 581; Giraud, *A. J. P.*, 1878, p. 127; also, denying explanation, Prillieux, *Compt.-Rend.*, t. lxxviii. p. 135.

merce. *Sennari* or *Gehzirah gum* was an inferior variety, yielding a mucilage which turned sour more quickly than that produced by Kordofan gum. It was collected in a country eastward of the White Nile, and in the region of the Blue Nile. Still farther to the eastward was collected the Suakin or Talca gum.

Egyptian gums consisted chiefly of small irregular fragments, interspersed with roundish pieces of various size, and containing much of that form of gum arabic which is characterized by innumerable minute fissures, pervading its substance and impairing its transparency.

The difference in the varieties mentioned is chiefly in regard to color, the inferior gums being more yellow or reddish, and usually containing also more impurities. Since the capture of Khartoum and the closure of the Soudan by the Mahdi, Egyptian gum has scarcely entered commerce as such, although a portion of the product probably gets into commerce through Morocco as Mogador gum. Geddah gum of the present time, sometimes spoken of as an Egyptian gum, enters commerce through Geddah, or Jidda, on the Arabian side of the Red Sea. It seems to be the same as *Mecca* or *El Wisch* or *Aden gums*, which are sometimes spoken of as Egyptian gums, but are probably produced in the triangular peninsula which forms the eastern extremity of Africa. These gums used to be exclusively collected at the Red Sea ports by Bombay merchants and carried to Bombay, where they were distributed, and hence have been known as *Bombay* or *India gum*. The finest specimens yield a useful mucilage, not quite so bland as that made from the best Egyptian gum. (See *India Gum.*)

Suakin Gum, Talca or *Talba Gum*, from *A. stenocarpa* and *A. seyal*, is exceedingly brittle, and usually semi-pulverulent. It is a mixture of nearly colorless and brownish gum, is exported at Alexandria, and is sometimes termed *gum savakin.*

2. Barbary Gum. (*Mogador Gum, Morocco Gum.*) Mogador, a port of Morocco, is the chief entrepôt of the trade. The gum is probably derived, in part at least, from *A. nilotica.* According to Jackson, the natives call the tree which affords it *attaleh.* They gather it in July and August, when the weather is hot and very dry. Two kinds are brought to Mogador, one from the neighboring provinces, the other by caravans from Timbuctoo. This may account for the fact that Barbary gum in part resembles the Turkey, in part the Senegal. When first deposited in the warehouses, it has a faint smell, and makes a crackling noise, occasioned by the rupture of the small masses as they become more dry. Barbary gum is usually in tears, somewhat brownish, roundish or vermiform, wholly soluble in water. It reaches the United States in casks through English commerce.

3. Senegal Gum. This variety was introduced into Europe by the Dutch. The French afterwards planted a colony on the western coast of Africa, and took possession of the trade. St. Louis, at the mouth of the Senegal, and Portendic, considerably farther north, are the ports in which the commerce in gum chiefly centres. Immense forests exist in the interior, containing many species of the genus Acacia, all of which are said to yield gum; as is affirmed do also various trees belonging to other genera. (*Journ. de Pharm.*, xxiv. 318.) The chief harvest begins in October and ends in December, although gum is also collected in March. The dry winds, which prevail after the rainy season, cause the bark to crack; the juice flows out and hardens in masses, which are often as large as a pigeon's egg, and sometimes as that of an ostrich. It is affirmed that the exudation is also largely caused by a parasitic plant, *Loranthus senegalensis*, the gummy exudation freely oozing out at the point where the parasite penetrates the bark. (*Pharm. Centralh.*, Aug. 1895.) Senegal gum is usually in roundish or oval unbroken pieces, or in straight or curled cylindrical pieces of various sizes, in the finest grades whitish or colorless, but generally yellowish, reddish, or brownish red. The pieces are larger than those of Turkey gum, less brittle and pulverizable, and breaking with a more conchoidal fracture.* According to L. Liebermann, gum Senegal can be distinguished from

* Dr. A. Corre divides the gum Senegal into the hard gums, which are of firm consistence, with a large, clear, shining fracture, and the soft or friable gums. For an account of the grades and varieties of these the reader is referred to the *Journ. de Pharm.*, xxiv. 318. *Galam* gum (*Gommes haut-du-fleuve*) is that coming from Galam, Podor, Bakel, and Medina; it is sometimes hard, sometimes soft. For an abstract of Soubeiran's paper on Galam gums, which is scarcely applicable to the present time, see 14th ed U. S. D. *Gommes bas-du-fleuve* are from the deserts of Bounou and the country of the Braknas.

Brittle gum, Salabreda, or *Sadra-beida*, is supposed to be obtained from *A. albida* of the Flora of Senegambia, which is much smaller than *A. verek*, and characterized by its white bark. The gum is usually in small, irregular pieces, like coarse salt, probably the fragments of larger lumps, but sometimes in vermicular pieces about as thick as a goose-quill, and of variable length. It is dull and often wrinkled externally, of a vitreous fracture, and of different tints of color, white, green, yellow, or orange. It is always somewhat bitter. Very easily soluble in its weight of water, it affords a mucilage of little consistence, which has but a slight effect on the tincture of litmus. When the solution is evaporated to the consistence of a paste, it absorbs moisture so as to become viscid; this property detracts much from its value. It is much less esteemed than the Galam gum.

Turkey gum arabic by heating the solutions for some time with potassium hydroxide. The gum Senegal does not alter in color, or becomes only very faintly yellow, while the Turkey gum arabic solution changes to an amber-yellow color (as do solutions of dextrin). (*A. J. P.*, 1891.)

4. India Gum.* Most of this gum is taken to Bombay in Arab vessels from Cape Gardafui and Berbera on the northeastern coast of Africa, where it is collected, or from the ports of the Red Sea. It is in pieces varying in size, color, and quality, some resembling the broken fragments of Turkey gum, though much less chinky; others large, roundish, and tenacious, like Senegal. It is often contaminated, containing, besides genuine gum arabic, portions of a different product, having the characteristic properties of Bassora gum. This is distinguished by its insolubility in water, with which, however, it unites, swelling up, and forming a soft viscid mass. It owes its properties to the presence of *bassorin*. Besides this impurity in the India gum, there are often others more readily detected. Among these we have observed a yellowish-white resinous substance, which has the sensible properties of the turpentines. If care be used in assorting this commercial variety, it may be employed for all the purposes of good gum arabic. India gum is brought to this country partly from Calcutta or Bombay, and partly by way of England. It usually comes in large cases. We have seen a parcel said to have come directly from the Red Sea, enclosed in large sacks made of a kind of matting, and bearing a close resemblance to the gum from Calcutta, except that it was more impure, and contained numerous large, irregular, very brittle masses, not much less than the fist in size.†

* *Persian gum*, which is said to be sent from Persia to Assowan to be packed as genuine gum arabic, can be distinguished from the latter, which it closely resembles, by its not dissolving in water. Professor Sickenberger thinks that it is the product of *Prunus Bokharensis* or of *P. Puddum*.

† In the *Journ. de Pharm. et de Chim.* (Oct. 1867, p. 270), a variety of the India gum, imported into France by way of London, in boxes containing about 400 pounds, is described as follows. It is a mixture of tears of various tints with impurities. In assorting it for use, the lightest-colored tears are selected. These are less perfectly transparent than gum arabic, less fissured on the surface, which is brilliant and often mammillated, and are also much less friable. But the most important distinctive character of this gum consists in its relations to water. If agitated with twice or thrice its weight of cold water, instead of forming, like ordinary gum arabic, a homogeneous, slightly mucilaginous solution, it forms a thick, transparent, very tenacious magma, which cannot be diluted with a larger quantity of water, but may, after a long time, be coarsely divided, still, however, retaining its viscid, ropy aspect, which never entirely disappears, whatever may be the quantity of water added. It imparts to syrup a very thick and very viscid consistence. It is important that the apothecary should be able to distinguish it, as it is unfit for ordinary pharmaceutic use, being employed exclusively by manufacturers in the preparation of cloths. All that is necessary is to add a few pieces to twice their weight of cold water, and allow the mixture to stand. After some hours, the peculiar, viscid mucilage above described betrays the character of the gum.

Substitutes for Gum Arabic.—The variety of true gum arabic which has received the name of India gum because it enters commerce through Bombay must be distinguished from the Indian gums which have been thrown into commerce as substitutes for true gum arabic. According to A. Mander, the East India gums appearing in the London market are:

(1) *Glassy Amrad Gum.*—A dark gum consisting of more or less rounded and some stalactitic pieces, with smooth shining surface and free from internal cracks. Color varying from dark brown to pale yellow. Viscosity of mucilage (acacia being 1), 2.

(2) *East India Amrad Gum.*—A dark brittle gum of a reddish tint, composed chiefly of transparent angular fragments with a few rounded masses having a conchoidal fracture. Viscosity of mucilage, 0·15.

(3) *Pale Amrad Gum.*—This somewhat resembles "gum acacia sorts," being in broken angular pieces or small tears, and these more or less cracked internally; some pieces may be noticed having an opaline surface. Viscosity of mucilage, 0·156.

(4) *Amra* or *Oomra Whatti Gum.*—A dark gum, in irregularly-shaped and stalactiform pieces, clear internally, but dull surface; color from reddish to pale yellow. Viscosity of mucilage, 1.8.

(5) *Ghatti Gum.*—A pale gum consisting of rounded or vermiform pieces varying in size, clear internally, but dull and roughened on the surface, apparently caused by shrinkage in drying; from brownish-yellow to perfectly colorless and transparent. Mucilage a pale yellowish-brown semi-solid mass.

Of these gums, India gums of the London market, the first four varieties yield mucilages which are so dark-colored that they cannot be used in practical pharmacy. One part of ghatti gum rubbed up with three parts of distilled water and strained, yields a mucilage which is tasteless, odorless, colorless, and which is superior to the emulsion of gum arabic in its adhesive power, and even in its emulsive power, the emulsion made with it being almost of snowy whiteness. Ghatti gum would therefore seem to be thoroughly adapted for the purposes of pharmacy, and its extreme cheapness will undoubtedly give it vogue.

The studies of J. G. Prebble, of Bombay, throw much light upon the gums just spoken of. Through Oomrawuttee, or Amravti, the chief town of the Hyderabad assigned districts known as the Beras, two gums enter the world's commerce, which are respectively known in India as *Amrad* or *Babool* gum, and *Ghatti* gum. The babool gum is apt to be dark, and is said to be a product of the *Acacia arabica*. It is without much doubt the *amra whatti* gum of Mander. *Amra* is the native name for a gum derived from *Spondias mangifera*, which gum, however, is said to resemble tragacanth rather than gum arabic. The Arabic word *hamrâ* means red, and possibly the term *amrad* is derived from it. The amrad gums of London appear to be made in Bombay by mixing babool gum with other gums collected in various parts of India or imported into Bombay from the Red Sea coast.

Ghatti gum is said to be obtained from *Anogeissus latifolia* in enormous quantities, to be much used in India, and to be exported from Bombay in the pure state.

Besides the India gum, numerous gums have entered commerce from South America, Cape of Good Hope, and Australia.

General Properties. Gum arabic is in roundish or amorphous pieces, or irregular fragments, of various sizes, more or less transparent, hard, brittle, pulverizable, and breaking with a shining fracture. It is usually white, or yellowish white, but frequently presents different shades of red, and is sometimes of a deep-orange or brownish color. It is bleached by exposure to the sun. In powder it is always white. It is inodorous, has a feeble, slightly sweetish taste, and when pure dissolves wholly in the mouth. The sp. gr. varies from 1·31 to 1·48 or 1·525 for the dried gum. "Acacia should be slowly but completely soluble in 2 parts of water. This solution shows an acid reaction with litmus paper, yields a gelatinous precipitate with basic lead acetate test-solution or ferric chloride test-solution, or concentrated solution of sodium borate, and does not reduce alkaline cupric tartrate volumetric solution. The powder is not colored blue (absence of *starch*), or red (absence of *dextrin*), by iodine test-solution." *U. S.* "When dissolved in an equal weight of *water*, the solution should neither form a glairy mucilage nor, after admixture with more *water*, should it yield a gummy deposit on standing. The aqueous solution forms with *solution of lead subacetate* an opaque, and with *solution of borax* a more or less translucent, white jelly; it gives no precipitate with *solution of lead acetate;* is not colored blue or brown by a small quantity of *solution of iodine* (absence of starch or of ordinary 'dextrin' of commerce) nor bluish-black by *test-solution of ferric chloride* (absence of tannic

Cape gums are imported into London in large quantities. Two varieties are recognized. The *glassy hard Cape gum*, the product of *Acacia horrida*, occurs in amber-brown-colored, irregular pieces, occasionally fissured, usually hard; soluble in water, giving a dark-colored viscid mucilage free from odor but with an unusual flavor. This gum is said to be bleached and mixed with a pale gum. The *soft Cape gum* is believed to be derived from *Acacia giraffæ*. Its inferior grades are dark brown and yield a bitter mucilage; the finest samples, however, so closely resemble, in their physical properties and the mucilage which they yield, the Kordofan gums, that some authorities believe that they are true gum arabic which has been deflected southward by the closure of the Soudan.

Australian gum, or *Wattle gum*, is the product of *A. pycnantha*, Benth.; *A. decurrens*, Willd.; *A. homalophylla* (A. Cunn), and probably other species of acacia. It is said that gums obtained near the coast and those procured in the interior do not contain metarabin. It occurs in hard pieces, elongated or globular; rough, varying in color from dark amber to pale yellow; entirely soluble in water, and yielding a very adhesive mucilage, which, when dry, is said not to crack. It sometimes contains tannin, and appears not to be suitable for pharmaceutical purposes. The wood of *A. homalophylla* is known as *violet wood*, on account of its pleasant odor. (*Amer. Drug.*, 1884.)

Under the name of *Brazilian gum*, *Para gum*, and *gum angico*, large quantities of a gum occurring in large dark-amber or dark-brown glossy drops, soluble in water, are yearly thrown into commerce. It is said to be the product of *Acacia angico*. Its mucilage is very adhesive, but usually too dark in color for pharmaceutical purposes. It must be distinguished from the gum resin often known as *Brazilian gum*, which is said to be obtained from *Hymenia courbaril*, and is used in making varnishes.

Chagual or *Maguey gum* of Chili occurs in hollow cylindrical pieces from 0·2 to 1·5 Cm. in thickness, occasionally having the form of stalactites or irregular tubers, but in nearly all cases showing the impression of the epidermis to which they have been attached. On their inner surface they are longitudinally streaked, while their outer surface is usually numerously fissured, the fissures penetrating deeply toward the interior. In the absence of these the pieces are of glassy brightness, transparent, and of very dense structure internally. The color varies from colorless, through yellowish and brownish to a tolerably deep brown, isolated pieces being almost black. Maceration in water is said to reduce the dark pieces to a granular mass, whilst the transparent pieces dissolve almost entirely; the whole of the commercial sample yielding about five or six per cent. to cold water. The amount dissolved is greatly increased by the use of boiling water. According to the experiments made by Guehm, the commercial drug is scarcely fitted for technical use as a gum, but the clear pieces when made into a concentrated mucilage by prolonged heating answer the purposes of the calico printer well. *Puya chilensis*, *P. lanuginosa*, and *P. lanata* are commonly said to be the sources of the gum, though the researches of Hartwich make this uncertain. The exudation is asserted to be the result of the bite of a caterpillar, *Kastina elegans*. (*Zeitschr. Oest. Apoth. Ver.*, Aug. 1, 1896.)

Thos. Maben gives the following method of testing mucilage obtained from various gums sold for gum arabic as the best that he has been able to devise after much experimentation. Two or three drops of the mucilage prepared from the gum are placed on a glass or porcelain slab, and one or two drops of the following reagents added; these are then stirred together with a glass rod and the results compared. In the case of borax, acacia mucilage at once agglutinates or hardens into a gummy mass, similarly with basic lead acetate and ferric chloride, whilst it gelatinizes or forms a softer mass with potassic silicate. Similar reactions are given by the Senegal gums, the Indian amrad gums, white Barbary, white and brown Cape, and Geddah gum. Barbary brown and amrad give only a jelly with borax, otherwise they react as acacia. Australian gum agglutinates with borax, but only gelatinizes with basic lead acetate, and has no reaction with ferric chloride and potassic silicate. Brazilian gum has no reaction with potassic silicate, but gelatinizes with borax and ferric chloride and slightly with basic lead acetate. Ghatti gum gelatinizes with all four reagents, but in a slight degree only with potassic silicate. Oomra gum reacts similarly to acacia, except that it is entirely unaffected by basic lead acetate, and forms a softer jelly with ferric chloride. There are, of course, shades of difference in the various reactions which cannot be indicated by these terms, but, generally speaking, a fair idea is given of the nature of the gum. (*Pharm. Journ. and Trans.*, March 1, 1890, 717–721.)

Schuhmann prepares *dextrin* by a registered process so as to replace gum arabic. The milk of starch is treated with one one-hundredth part of its weight in starch, of hydrochloric, nitric, or sulphuric acid. In twenty-four hours the mixture is washed until the waters give no acid reaction. The starch paste thus prepared is diluted to a thick pap, and heated in a digester to 160–170° C.; or it may be treated in a closed vessel under ordinary pressure, with a current of superheated air or vapor, until the product ceases to color with iodine. The soluble product thus obtained is diluted to 20–25° Baumé, and—a little albumen being added—is heated to the boiling point and passed into a Taylor apparatus, or into a press-filter, in which it is clarified and made colorless with bone-black. Thus purified it is evaporated to a proper consistence, or may be reduced to dryness. A small quantity of vegetable gum may be added with advantage. The mass obtained by this process is entirely soluble in warm or cold water; it is odorless and tasteless, and greatly resembles gum arabic in aspect and properties. (*Moniteur Scientifique*, 1888.)

acid); and does not give a red precipitate when boiled with *solution of potassio-cupric tartrate* (absence of certain sugars). Gum Acacia should not yield more than 4 per cent. of ash." *Br.* The commercial gum arabic contains 17 per cent. of water and 3 per cent. of ash, consisting almost entirely of calcium, potassium, and magnesium carbonates.

The gum dissolves at ordinary temperature slowly, in an equal weight of water, forming a thick glutinous liquid of distinctly acid reaction. It is insoluble in alcohol, ether, and the oils. 100 parts of diluted alcohol containing 22 per cent. of alcohol by volume dissolve 57 parts of gum, diluted alcohol containing 40 per cent. alcohol takes up 10 parts, and 50 per cent. alcohol only 4 parts (Flückiger). On adding hydrochloric acid to the aqueous solution and precipitating with alcohol, a colorless amorphous substance is obtained. This is *arabic acid.* On hydrolysis, it yields *galactose*, *arabinose*, and a pentabiose named *arabinon.* The *arabin* (or arabic acid) may also be prepared by placing a solution of gum, acidulated with hydrochloric acid, on a dialyzer, when calcium chloride will diffuse out, leaving behind solution of arabin.

Arabic acid dried at 100° C. (212° F.) has the composition $2C_5H_{10}O_5 + H_2O$, and gives up H_2O when it unites with bases. It has a decided tendency to form acid salts. Concentrated nitric acid forms with it nitro-compounds; dilute nitric acid, on the other hand, gives rise to mucic and saccharic acids, together with oxalic and a little tartaric acid. Dilute sulphuric acid on prolonged boiling gives rise to *arabinose*, or *arabin sugar* (*pectinose*, or *pectin sugar*), $C_5H_{10}O_5$, which reduces alkaline copper solution and turns the plane of polarization 121° to the right. Kiliani (*Ber. d. Chem. Ges.*, 1887, p. 339) first established the formula as given above, and it is now recognized as belonging to the newly-established class of *pentoses.* They are not fermentable, and on prolonged boiling with dilute hydrochloric acid, lose the elements of water and yield *furfurol*, $C_5H_4O_2$.

Neutral lead acetate does not precipitate an aqueous solution of gum arabic, but the basic acetate forms even in a very dilute solution a precipitate.

Prolonged heating of the dry gum causes it to change readily into *metarabic* (*metagummic*) acid, which is identical with the *cerasin* found in the beet and in cherry-gum. Sulphuric acid will also change arabic into metarabic acid. 25 Gm. pure gum arabic are covered with 50 C.c. strong alcohol, 10 C.c. water, and 5 C.c. sulphuric acid, and allowed to stand 24 hours. On pouring off the fluid, and washing the residue with alcohol and with water, metarabic acid remains behind as a voluminous mass, which dries to a white, tasteless, and odorless powder of acid reaction. (*Graeger, Jahresbericht der Chem.*, 1872, p. 781.) The *metapectic* acid prepared by Scheibler from the sugar beet is identical with this.

The principle separated by cold water from the soluble arabin proves to be the same as the metarabic (metagummic) acid prepared direct from the pure gum arabic by heating, or by the action of sulphuric acid. It is also identical with gum extracted from the sugar beet by Scheibler. In the normal and sound beet this gum is insoluble in water, and merely swells up like the metarabic acid, while in altered beets there is found a portion (arabin) soluble in water. (Scheibler, *Ber. Chem. Ges.*, 1873, p. 612.)

The similarity of the reactions and composition of *arabinose* and *galactose* (from sugar of milk by inversion) led Kiliani to assert the identity of these two varieties of sugar, but later studies by himself, Claesson, and Scheibler have shown that they are distinct. Thus, galactose is fermentable, while arabinose is not; galactose yields mucic acid when oxidized with nitric acid, and dulcite when reduced with sodium amalgam, while arabinose does not yield either; the fusing-point of the crystallized galactose is given at 142–144° C., while that of arabinose is 160° C.; galactose yields with phenylhydrazin a light-yellow compound, fusing at 170–171° C., while arabinose forms a brownish-yellow compound, fusing at 157–158° C. (Scheibler, *Ber. d. Chem. Ges.*, 17, p. 1731.) Arabinose is said to be obtainable only from those varieties of gum arabic that yield no mucic acid when treated with nitric acid. (Claesson, *Ber. d. Chem. Ges.*, 14, p. 1271.)

Gum arabic undergoes no change by age, when kept in a dry place. Its concentrated aqueous solution remains for a considerable time unaltered, but ultimately becomes sour, from the production of acetic acid. The disposition to sour is increased by employing hot water in making the solution. The tendency of a weak solution to become mouldy is said to be obviated by adding a few drops of sulphuric acid, and decanting from the calcium sulphate deposited. (*A. J. P.*, 1872, p. 353.) Solution of gum arabic does not ferment upon the addition of yeast, saliva, or gastric juice; the addition of chalk and cheese, however, starts a fermentation which gives rise to lactic acid and alcohol, but not to mannite or glycerin. The addition of a solution of gum to an acidified albumen solution causes a precipitate, which disappears on further addi-

tion of gum, but the solution will then curdle and become flocculent on application of heat. Gum may be distinguished from dextrin by the following tests: 1. Gum contains no dextroglucose, which, however, is present in dextrin, and may be recognized by the copper test.* 2. Gum contains a lime compound; hence its solution is rendered milky by oxalic acid, while a solution of dextrin remains almost clear. 3. Gum gives a shiny, yellow deposit when its solution is mixed with a neutral ferric salt. (Hager, *Chem. Central.*, 1873, pp. 408 and 584.)

The properties above enumerated belong to gum arabic generally. There are, however, pharmaceutic varieties with differences which deserve notice. 1. *Gum that is transparent and readily soluble.* This constitutes by far the greater portion of the commercial varieties distinguished by the names of Turkey and Senegal gum. It is characterized by its transparency, ready solubility, and the comparatively slight degree of thickness and viscidity of its solution. Under this head may be included the *gomme blanche fendillée* of Guibourt. It is distinguished by the whiteness and deficient transparency of the pieces, attributable to the minute cracks or fissures with which they abound, and which render them very brittle and easily pulverizable. This peculiar structure is generally ascribed to the influence of solar heat and light, but is conjectured by Hayne to arise from the exudation of the juice in the frothy state noticed by Ehrenberg. Though the unbroken pieces are somewhat opaque, each minute fragment is perfectly transparent and homogeneous. This variety, in consequence of its prompt and entire solubility, is usually preferred for medical use, and for most purposes in pharmacy. 2. *Gum less transparent and less soluble.* Guibourt has proposed for portions of this gum the name of *gomme pelliculée*, from the circumstance that the masses are always apparently covered, on some part of their surface, by a yellowish opaque pellicle. Other portions of it have a mammillary appearance on the surface. It is less transparent than the former variety, is less freely and completely dissolved by water, and forms a more viscid solution. It dissolves with difficulty in the mouth, and adheres tenaciously to the teeth. It is found in all the commercial varieties of gum, but least in that from Egypt. Its peculiarities have been ascribed to variable proportions of *bassorin* or *cerasin* associated with the soluble *arabin*. Between these two varieties of gum there are insensible gradations, so that it is not always easy to classify specimens.

Specimens of gum arabic are sometimes found in commerce which are soluble in water with difficulty. According to Köchlin, if ten parts of such gum, fifty parts of water, and three parts of a 12 per cent. solution of hydrogen peroxide be heated together for two or three hours, the gum is rendered easily soluble. (*Nat. Drug.*, 1894, 176.) Related to the acacia gums are *wood-gum*, from the wood of foliage trees, yielding xylose on hydrolysis; *cherry-gum*, the gum of cherry and almond trees, yielding *b*-arabinose on hydrolysis; *peach-gum*, from the peach tree, yielding arabinose and galactose on hydrolysis; *barley-gum*, obtained in the nitrogen-free extractive material of cereals, yielding galactose and xylose. Martina examined twenty-seven varieties of gum, and the composition of some of the principal ones is given in the table:

Origin.	Source.	Ash.	Lime.	Mucic Acid.	Galactose.	Furfurol.	Penta-glucose.	Total Glucoses.
Gum Arabic	Arabia	3·60	1·84	22·98	30·66	13·57	27·14	58·3
	Senegal . . .	3·25	0·90	19·72	26·29	12·97	25·94	57·58

* See Volumetric Solution Alkaline Cupric Tartrate (PART III.). J. Henry Schroeder examined twelve specimens of powdered acacia, and states that dextrin is not frequently used as an adulterant, and that if in using the alkaline cupric tartrate test the heat be prolonged during twenty minutes, a well-defined reduction was produced even when pure Senegal gum was used. This fact should be remembered in testing gums by the official method. (*A. J. P.*, 1897, 195.) The following test is given in the *Pharm. Post*, 1894, 563. Add 3 C.c. of a solution consisting of 15 drops Liquor Ferri Chloridi, 15 drops of a saturated solution of potassium ferrocyanide, 5 drops of HCl (1·125), and 60 C.c of water to 20 per cent. solution of the gum. If the gum arabic is pure, it will remain a clear yellow for from eight to ten hours. If there is dextrin present, the color changes to a blue.

Impurities and Adulterations. In parcels of gum arabic there are sometimes pieces of a dark color, opaque, and incorporated with ligneous, earthy, or other impurities. The inferior are often mixed with, or substituted for, the better kinds, especially in powder; and portions of insoluble gum, bdellium, and other concrete juices of unknown origin, are found among the genuine. Flour or starch is sometimes fraudulently added to the powder, but is easily detected by the blue color which it produces with tincture of iodine. In consequence of the impurities and difference in quality, gum arabic should generally be assorted for pharmaceutic use. A foreign substance sometimes adheres to its surface, giving it a bitter taste, from which it may be freed by washing in water. Various adulterations of gum arabic have been practised, and substitutes offered for sale either honestly or with false labels. The high price of the genuine gum of late years has greatly stimulated the exploiting of these products. Starch, especially rice-starch, which is difficult of detection on account of the small size of its granules, dextrin, and inferior gums are often added to powdered gum arabic. These foreign substances can usually be detected by the microscope or by appropriate tests for starch or dextrin even in powdered gum. It has been proposed to change the arabinic acid of the sugar beet, by the method of Scheibler, into metarabinic acid, as the foundation of a true artificial gum arabic, but the *artificial* gums of the market have no such close chemical relation with the natural gum; many of them are mixtures of various substances, others are produced from starch by the action of sulphuric acid or by other means. *Universal gum*, a patented product obtained from potato starch, has been highly commended for the permanency and adhesiveness of its mucilage, but is said not to act well as an emulsifier. A substitute has also been made from Irish moss. (See *Chondrus.*)

Medical Properties and Uses. Acacia is used in medicine chiefly as a demulcent. By the viscidity of its solution, it serves to cover and sheathe inflamed surfaces, and, by blending with and diluting irritating matters, blunts their acrimony. Hence it is advantageously employed in catarrhal affections and irritation of the fauces, by being held in the mouth and allowed slowly to dissolve. Internally administered, it has been found useful in *inflammations* of the *gastric* and *intestinal mucous membrane;* and its employment has even been extended to similar affections of the lungs and urinary organs. Whether it is beneficial, in the latter cases, in any other manner than by the dilution resulting from its watery vehicle, is doubtful. It has been used as a food, but has very little if any nutritive value. In pharmacy, gum arabic is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches. Two kinds of powdered gum arabic are used, one a coarse powder called *granulated*, the other *finely dusted*. The granulated dissolves more readily in water, according to Hager, because it has lost during desiccation only two per cent. of moisture, whilst in preparing the "finely dusted" powder the high heat necessarily used to thoroughly dry it, drives off ten per cent. of water. Its easy solubility and absence of tendency to form "lumps" cause the coarse powder to be preferred for solutions, emulsions, etc.

ACETANILIDUM. U. S., Br. Acetanilid. [Phenylacetamide.]

$C_6H_5NH.C_2H_3O$; 134·73. (ĂÇ-Ē-TĂN-I-LĪ'DŬM.) $C_6H_5NH.C_2H_3O$; 135.

"An acetyl derivative of aniline." *U. S.* "Acetanilide, $CH_3.CO.NH.C_6H_5$, may be obtained by the interaction of glacial acetic acid and aniline." *Br.*

Acetanilide; Antifebrin.

Acetanilid is a new official compound of the Pharmacopœia of 1890; its extensive use as an antipyretic under the name of antifebrin justifying its promotion to this position. Unlike many of the antipyretics and synthetical compounds introduced into the materia medica of late years, the process for its manufacture is not patented.

Preparation. Acetanilid is made, according to Yvon, as follows. 372 grammes of pure aniline and 240 grammes of glacial acetic acid are heated for four hours to the boiling point in a flask provided with a reversed condenser; the excess of both ingredients is then distilled off on a sand-bath, this being completed when the temperature reaches 260° C. The cooled, congealed residue is crude acetanilid, which may be purified by sublimation, or better by repeated crystallization from water. The yield is about 400 Gm. It may also be prepared by acting on aniline with acetyl chloride (Gerhardt) or by heating aniline with acetamide (Kelbe). The sublimed salt is whiter and lighter than that obtained by crystallization, which has the appearance of boric acid.

Properties. Acetanilid is described by the U. S. Pharmacopœia as in "White, shining, micaceous, crystalline laminæ, or a crystalline powder, odorless, having a faintly burning taste, and permanent in the air. Soluble, at 15° C. (59° F.), in 194 parts of water, and in 5 parts

of alcohol; in 18 parts of boiling water, and in 0·4 part of boiling alcohol; also soluble in 18 parts of ether, and easily soluble in chloroform. When heated to 113° C. (235·4° F.), Acetanilid melts. Upon ignition, it is consumed without leaving a residue. Acetanilid is neutral to litmus paper. When agitated with colorless, concentrated sulphuric acid, in a clean test-tube, Acetanilid dissolves without imparting color to the liquid. On heating about 0·1 Gm. of Acetanilid with a few C.c. of concentrated solution (1 in 4) of potassium or sodium hydrate, the characteristic odor of aniline becomes noticeable. On now adding chloroform, and again heating, the disagreeable odor of phenyl isocyanide (which is poisonous) is evolved. On boiling 0·1 Gm. of Acetanilid for several minutes with 2 C.c. of hydrochloric acid, a clear solution results which, when mixed with 3 C.c. of a 5-per-cent. aqueous solution of carbolic acid, and afterwards with 5 C.c. of a filtered, saturated solution of chlorinated lime (*Calx chlorata*), acquires a brownish-red color, becoming blue upon supersaturation with ammonia. A cold saturated, aqueous solution of Acetanilid, added to ferric chloride test-solution, should not affect the color of the latter (absence of *aniline salts* and *various allied substances*)." *U. S.* "Melting point, when dry, 236·5° F. (113·5° C.). It is soluble in 200 parts of cold or 18 parts of boiling *water*, and in 4 parts of *alcohol* (90 per cent.), freely soluble in *ether*, *benzol*, and *chloroform*. On boiling with *test-solution of ferric chloride* a reddish-brown color is produced, and this is almost entirely discharged by *hydrochloric acid*. If Acetanilid be heated with *solution of potassium hydroxide* until the odor of aniline is given off, and the liquid be then warmed with a few drops of *chloroform*, the unpleasant and penetrating odor of phenyl-isonitrile (isocyanide) is developed; and an aqueous solution mixed with *solution of bromine* gives a yellowish-white precipitate (distinctions from phenacetin). Heated with free access of air it burns, leaving no residue. With *sulphuric acid* or with cold *nitric acid* it forms a colorless solution. A cold saturated aqueous solution does not affect *solution of litmus* (absence of free acid), and is not affected by *test-solution of ferric chloride* (absence of acetone, phenazone, and salts of aniline)." *Br.* Additional tests for acetanilid have been proposed by Charles Platt, for which see *Amer. Drug.*, 1896, 122.

Ritsert (*Pharm. Zeitung*, 1890, p. 306) believes that the difference in melting point of acetanilid given by various writers is due to the almost constant presence of toluidine in aniline, and the production of acettoluids which have the following melting points: *ortho*, 107°; *meta*, 65·5°; and *para*, 147° C. A very important reaction, by which acettoluid may be detected in acetanilid, is in the use of a boiling solution of potassium permanganate; acetanilid, if pure, is not altered, and does not reduce the permanganate, while acettoluid is oxidized to acetamidobenzoic acid with reduction of the permanganate; of a number of samples of acetanilid examined, only one showed a slight reduction, all the others a decided reduction.

Medical Properties and Uses. The effects of antifebrin upon man are very similar to those produced by antipyrin,—namely, after small doses, quietness; after very large doses, malaise, a little headache, singing in the ears, weakness, and a peculiar cyanosis, with some tendency to somnolence, mydriasis, and, if there has been fever, marked fall of temperature usually accompanied by, but not dependent upon, a profuse sweat. After enormous doses complete coma and collapse have been noted. It has in rare instances caused collapse and cardiac failure, and a peculiar measles-like eruption is not very uncommon. Large toxic doses have caused in animals and in man anæsthesia, loss of reflex activity, tremors, irregular failing respiration, convulsions, coma, and general paralysis. The cyanosis is due to the formation of methæmoglobin in the blood. In the animal system the antifebrin appears to break up into acetic acid and aniline, the aniline in turn undergoing oxidation into *paramidophenol*, which unites with sulphuric acid to be eliminated as paramidophenol sulphate.

Sembritzki is said to have seen collapse after five grains (0·323 Gm.) of acetanilid, and Dr. W. H. Thomas (*Indiana Med. Journ.*, Sept. 1890) details a case in which he attributes death from heart-failure to five grains (0·323 Gm.). In a number of cases a drachm (3·88 Gm.) has been followed by serious collapse; but J. Wolf reports recovery after about one ounce (31·1 Gm.).

There is a wide-spread but perhaps not well-grounded belief in the profession that accidents are more rare after antifebrin than after antipyrin, but the medical application of antifebrin seems to be identical with that of antipyrin, save only as it is modified by the insolubility of antifebrin. Antifebrin is also somewhat more powerful than antipyrin, its full dose being ten grains (0·647 Gm.), repeated if necessary; preferably administered in capsules or wafers. For details of medical use, see *Phenazonum*. Acetanilid is germicidal, and seems to be especially active in inhibiting the growth of pathogenetic organisms. It is also analgesic, and affords a very useful dressing for wounds and ulcers. The drug itself may be freely used in the form of a fine powder, or an ointment may be employed in the strength of from 10 to 50 per cent.

In certain mucous inflammations, as *vaginitis* and *urethritis*, a local application (20 to 40 grains to the fluidounce) has been found very effective. Poisoning has resulted from the too free external use of acetanilid. (See *Philada. Polyclinic*, 1897; *Atlantic Med. Weekly*, 1898.) Acetanilid may be given suspended in mucilage of acacia and syrup, or in capsule. Dose, from five to fifteen grains (0·323 to 0·97 Gm.).

ACETUM CANTHARIDIS. Br. Vinegar of Cantharides.

(Ą-CĒ'TŬM CĄN-THĂR'Į-DĪS.)

Vinaigre cantharidé, *Fr.;* Canthariden-Essig, *G.*

"Cantharides, bruised, 2 *ounces* (Imperial) or 100 grammes; Glacial Acetic Acid and Distilled Water, mixed in equal volumes, a sufficient quantity. Macerate the Cantharides in *eighteen fluid ounces* (Imp. meas.) or nine hundred cubic centimetres of the mixture of Glacial Acetic Acid and Distilled Water for twenty-four hours; transfer to a percolator; when the liquid ceases to pass, pour sufficient of the menstruum in successive portions over the contents of the percolator to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Vinegar of Cantharides." *Br.*

This preparation was formerly official in all the Pharmacopœias of the British Islands; but it was omitted in the first British Pharmacopœia, to be resumed in the last two revisions. The mode of preparation differs mainly in the partial substitution of percolation for maceration and expression. Glacial acetic acid is now directed to be mixed with an equal volume of distilled water as the menstruum. This is an improvement over the former method of mixing two kinds of acetic acid of different strengths.

This preparation is intended exclusively for external use, as a speedy epispastic. It is said, when lightly applied by a brush, to act as a rubefacient; and, when rubbed freely upon the skin for three minutes, to be followed in two or three hours by full vesication. The pain produced by the application, though more severe, is also more transient than that occasioned by the blistering cerate. From experiments made by Mr. Redwood, it may be inferred that the old Acetum Cantharidis of the London Pharmacopœia, which was prepared by maceration without heat, proved epispastic chiefly if not exclusively in consequence of its acetic acid, and that it contained little of the active principle of the flies. (*P. J. Tr.*, Oct. 1841.) Prof. Procter found that, by digestion at a temperature of 100° C. (212° F.), the active principle of the flies is readily taken up by official acetic acid, though a portion of the cantharidin is deposited upon cooling. (*A. J. P.*, xxiv. 299.) It would seem, therefore, that the vinegar of Spanish flies would be best prepared with the aid of heat; and, to a certain extent, this advantage is enjoyed in the present process.*

ACETUM IPECACUANHÆ. Br. Vinegar of Ipecacuanha.

(Ą-CĒ'TŬM ĬP-Ę-CĂC-Ū-ĂN'HÆ—ĭp-ę-căc-ū-ān'ē.)

Vinaigre d'Ipecacuanha, *Fr.;* Brechwurzel-Essig, *G.*

"Liquid Extract of Ipecacuanha, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Diluted Acetic Acid, 17 *fl. ounces* (Imp. meas.) or 850 cubic centimetres. Mix; filter, and if necessary add sufficient Diluted Acetic Acid to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Vinegar of Ipecacuanha." *Br.*

The process for this vinegar was changed materially in the last revision of the British Pharmacopœia, liquid extract of ipecacuanha diluted with a mixture of alcohol and diluted acetic acid replacing the old method of percolating the drug with diluted acetic acid. It will be found, however, that after the vinegar has been made a few months the odor of acetic ether will be developed; this is sometimes objectionable. The words in the process "if necessary" might have been omitted, as slight loss in filtration always occurs. Diluted Acetic Acid

* The *vinegar of colchicum* (*acetum colchici*) was omitted in the U. S. Pharmacopœia, 1870, although a very active preparation. The following is the article on it in the 14th edition of the U. S. Dispensatory. "Take of Colchicum Root, in fine powder, *two troyounces;* Diluted Acetic Acid *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Acetic Acid, allow it to stand for half an hour, pack it firmly in a conical glass percolator, and gradually pour upon it Diluted Acetic Acid until the filtered liquid measures two pints. Vinegar of Colchicum may also be prepared by macerating the Colchicum Root, in moderately fine powder, with two pints of Diluted Acetic Acid, in a close glass vessel, for seven days; then expressing the liquid, and filtering through paper."

Vinegar is an excellent solvent of the active principle of colchicum; and the alkaloid of the latter loses none of its efficacy by combination with the acetic acid of the former. Of the two formulas above given, the first, directing percolation, is much preferable to the second, permitting maceration, if performed by competent hands; and the same remark will apply to all the medicated vinegars in which an alternative formula is given.

Medical Uses. This preparation is effective in doses of from thirty drops to two fluidrachms (1·9–7·5 C.c.).

is a good menstruum for ipecacuanha, and this vinegar will doubtless prove effective as an expectorant. The dose is from five to forty minims (0·31 to 2·46 C.c.).

ACETUM OPII. U.S. Vinegar of Opium.

(Ą-CĒ'TŬM O'PĬ-I.)

Black Drop; Vinaigre d'Opium, *Fr.*; Opium-Essig, *G.*

"Powdered Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Nutmeg, in No. 30 powder, *thirty grammes* [or 1 ounce av., 25·5 grains]; Sugar, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Acetic Acid, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 2 pints, 14·5 fluidrachms]. Macerate the Opium and Nutmeg in *five hundred cubic centimeters* [or 1 pint] of Diluted Acetic Acid during seven days, frequently stirring; then strain through muslin of close texture, and express the liquid. Mix the residue with *two hundred cubic centimeters* [or 7 fluidounces] of Diluted Acetic Acid to a uniform magma, and strain and express again. Mix and filter the strained liquids, dissolve the Sugar in the filtrate, and pass enough Diluted Acetic Acid through the filter to make the product measure *one thousand cubic centimeters* [or 2 pints, 14·5 fluidrachms]." *U.S.*

The U. S. P. 1890 now directs this vinegar to be tested to show its alkaloidal value as follows: "To assay this preparation, transfer 100 C.c. of it to a small capsule, add 4 Gm. of precipitated calcium carbonate, or such a quantity as will be sufficient to neutralize the free acid, and then proceed further as directed under *Tinctura Opii*. It should yield from 1·3 to 1·5 Gm. of crystallized morphine."

Many will doubtless prefer to make this preparation entirely by maceration. This may be done by placing the powder in a suitable bottle and pouring on the diluted acetic acid, agitating frequently, after allowing the maceration to proceed seven days, expressing, and filtering. The vinegar of opium was introduced into the Pharmacopœias as an imitation of *Lancaster* or *Quaker black drop*, or simply *black drop*. The formula of the first edition of the U. S. P. was so deficient in precision, and so uncertain in its results, that it was abandoned in the second edition; but, as these objections were obviated in a process by Mr. Charles Ellis (*A. J. P.*, vol. ii. p. 202), it was deemed proper to restore it to its official rank at the subsequent revision of the Pharmacopœia. The advantages of the black drop over laudanum are, probably, that disturbing principles contained in opium and soluble in alcohol are left behind by the aqueous menstruum employed, while the morphine meconate is converted by the acetic acid into the acetate. In the original process, published by Dr. Armstrong, who found it among the papers of a relative of the proprietor in England, *verjuice*, or the juice of the wild crab, was employed instead of vinegar. Other vegetable acids also favorably modify the narcotic operation of opium; and lemon-juice has been employed in a similar manner with vinegar. For the process official in the first ed. U. S. Pharm., see 14th edition U. S. Dispensatory.

The vinegar of opium may sometimes be advantageously used when opium itself, or the tincture, occasions headache, nausea, or nervous disorder. Formerly black drop was double the strength of laudanum; now it has the same strength. The smallness of the dose was one of its great advantages, but since the weakening, first authorized by the U. S. Pharmacopœia of 1880, this preparation has almost entirely gone out of use. The dose of vinegar of opium may be stated at from ten to fifteen drops (0·60 to 1 C.c.).

ACETUM SCILLÆ. U.S., Br. Vinegar of Squill.

(Ą-CĒ'TŬM SQĬL'LÆ.)

Vinaigre scillitique, *Fr.*; Meerzwiebel-Essig, *G.*

"Squill, in No. 30 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Diluted Acetic Acid, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 2 pints, 14·5 fluidrachms]. Macerate the Squill with *nine hundred cubic centimeters* [or 30 fluidounces] of Diluted Acetic Acid during seven days, frequently stirring; then strain through muslin, and wash the mass on the strainer with enough Diluted Acetic Acid, until the strained liquid measures *one thousand cubic centimeters* [or 2 pints, 14·5 fluidrachms]. Finally filter." *U. S.*

"Squill, bruised, 2½ *ounces* (Imperial) or 125 grammes; Diluted Acetic Acid, 1 *pint* (Imp. meas.) or 1000 cubic centimetres or a sufficient quantity. Exhaust the Squill by the process of maceration as directed for Tinctures. The resulting Vinegar of Squill should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

Vinegar of Squill may also be prepared by percolating the Squill with the Diluted Acetic Acid after previous maceration with an equal bulk of the Diluted Acetic Acid (this precaution being necessary in order to satisfy thoroughly its tendency to swell) and filtering through paper.

The process now official differs from that of the Pharmacopœia of 1880 in directing maceration instead of percolation.

This was formerly an official of the Lond., Ed., and Dub. Colleges, but was omitted as a distinct preparation in the first British Pharmacopœia, to be reintroduced into the present edition. As vinegar of squill is apt to be injured by keeping, it should be prepared in small quantities, as wanted for use. The British preparation is a trifle stronger than that of the U. S. P. 1890. As was shown by Mr. E. Gregory (*Canad. Pharm. Journ.*, Oct. 1875), the spirit added to it in the former British formula was of no use as a preservative. In the German Pharmacopœia one part of squill is macerated in a mixture of nine parts of pure vinegar and one part of alcohol for three days, with frequent shaking, expressed, and filtered. In the Codex twelve parts of white vinegar are used to macerate one part of squill for eight days. Vinegar of squill is employed chiefly in preparing the syrup. Upon standing, it deposits a precipitate, consisting, according to Vogel, of calcium citrate and tannic acid.

Medical Uses. This preparation has all the properties of the squill in substance, and is occasionally prescribed, but the syrup is usually and very properly preferred. The dose is from fifteen minims to a fluidrachm (0·92–3·69 C.c.); but the latter quantity would be apt to nauseate. It should be given in cinnamon-water, mint-water, or other aromatic liquid.

ACIDUM ACETICUM. U.S., Br. Acetic Acid.

(ĂS′Ĭ-DŬM Ȧ-CĒT′Ĭ-CŬM.)

"A liquid composed of 36 per cent., by weight, of absolute Acetic Acid [$HC_2H_3O_2 = 59{\cdot}86$], and 64 per cent. of water." *U. S.* "Acetic acid is a product of the destructive distillation of wood, and of the oxidation of ethylic alcohol. 100 parts by weight should contain 33 parts of hydrogen acetate, $CH_3.COOH$, and 67 parts of water." *Br.*

Acidum Aceticum Dilutum, *P. G.;* Acetum Concentratum; Acide acétique, *Fr.;* Essigsäure, *G.*

ACIDUM ACETICUM DILUTUM. U.S., Br. Diluted Acetic Acid.

(ĂS′Ĭ-DŬM Ȧ-CĒT′Ĭ-CŬM DĬ-LŪ′TŬM.)

"Diluted Acetic Acid contains 6 per cent., by weight, of absolute Acetic Acid." *U. S.* "100 parts by weight should contain 4·27 parts of hydrogen acetate, $CH_3.COOH$." *Br.*

Acetum, *P. G.;* Acetum Destillatum; Acide acétique dilué, *Fr.;* Reiner Essig, *G.*

ACIDUM ACETICUM GLACIALE. U.S., Br. Glacial Acetic Acid.

$HC_2H_3O_2$; 59·86. (ĂS′Ĭ-DŬM Ȧ-CĒT′Ĭ-CŬM GLĀ-CĬ-Ā′LĒ.) $HC_2H_3O_2$; 60.

"Nearly or quite absolute Acetic Acid." *U. S.* "100 parts by weight should contain 99 parts of hydrogen acetate, $CH_3.COOH$." *Br.*

Acidum Aceticum, *P. G.;* Acidum Aceticum Concentratum; Acetum glacialé, Acide acétique concentré, Vinaigre glacial, *Fr.;* Essigsäure, Eisessig, *G.*

Three strengths of acetic acid are now official in the U. S. and Br. Pharmacopœias. These are *Acidum Aceticum Glaciale*, of sp. gr. 1·058, *U. S.* and *Br.*, *Acidum Aceticum*, of sp. gr. 1·048, *U. S.*, and 1·044, *Br.*, and *Acidum Aceticum Dilutum*, sp. gr. 1·008, *U. S.*, and 1·006, *Br.*

We shall consider these grades separately, in the order of their strength.

Acidum Aceticum Glaciale. A process for this preparation was given in the British Pharmacopœia of 1864, which consisted in first heating sodium acetate so as to drive off all its water of crystallization, then, after cooling, distilling it with concentrated sulphuric acid, and, finally, if the resulting acetic acid, upon being tested with a mixture of solution of potassium iodate and a little mucilage of starch, was found to contain sulphurous acid, agitating the distilled acid with perfectly dry black manganese oxide, and again distilling. The object of the process was to furnish an acid of the maximum strength. But, on trial, it was not found to be satisfactory, as the resulting acid was not truly glacial, and always contained sulphurous acid. (C. H. Wood, *P. J. Tr.*, July, 1867, p. 17.) The following modification of the process does, however, yield a pure product. After the crystallized salt has been fused in an iron dish in its own water of crystallization, and has dried out, by increased heat it is again brought to fusion, whereby, if the heat applied be not too strong, no acid is decomposed or vaporized. The anhydrous salt is then treated with half a molecule of sulphuric acid (for 32 parts anhydrous acetate 49 parts of strongest sulphuric acid), which according to Mohr, *N. Rep. Phar.*, 22, p. 28 (1873), and Buchner, *N. Rep. Phar.*, 22, p. 32 (1873), suffices, instead of twice the amount, usually employed. No sulphurous acid is liberated in this case. A process to be followed on a large scale, practically the counterpart of this, is given in a footnote, page 18, 14th ed. U. S. Dispensatory.

Acetic acid of maximum strength may also be obtained by distilling acid potassium acetate at a heat between 199° C. (390° F.) and 299° C. (570° F.) One molecule of monohydrated acetic acid distils over, and neutral potassium acetate is left. The acid acetate may be formed by evaporating a mixture of the neutral acetate with an excess of watery acetic acid. In this process, the same potassium acetate serves repeatedly for conversion into acid acetate, and subsequent decomposition. This process is said to be employed by manufacturers on a large scale in some parts of the continent of Europe. It originated with M. Melsens.

Acidum Aceticum, *U.S.*, *Br.* (sp. gr. 1·048, *U.S.*, 1·044, *Br.*). *Acetic Acid.* This is the acid resulting from the purification of the crude acetic acid obtained by the destructive distillation of wood. It is the acid most useful to the apothecary. As this grade of acid has its source in the impure acetic acid obtained by the destructive distillation of wood, it will be proper to premise some account of the crude acid, called *crude pyroligneous acid.*

Wood, when charred, yields many volatile products, among which are an acid liquor, an empyreumatic oil, and tar containing creosote and some other proximate principles. When the carbonization is performed in close vessels, these products, which are lost in the ordinary process of charring, may be collected, and, at the same time, a large amount of charcoal be obtained.

Senff has furnished some comparative results in respect to the dry distillation of wood. The points worked out are a comparison of the products of distillation under similar conditions yielded by wood from various parts of the same trees, and from the same wood in a healthy and in an unsound state; also a comparison of the products from one and the same wood distilled slowly and distilled rapidly. It has been found that when similarly distilled the yield by weight of crude acid, tar, charcoal, and gas from the most diverse species of wood does not essentially differ, but that the percentage of real acid in the crude acid obtained varies considerably, and in this respect the wood from ordinary foliage trees compares favorably with that from needle-leaved trees; also that stem-wood yields more acid than branch-wood, that wood yields more acid than bark, and that sound wood yields more acid than unsound wood. (*Ber. d. Deutsch. Chem. Ges.*, xviii. p. 60; *P. J. Tr.*, 1885, p. 696.) These results are readily seen in the accompanying table:

		Charcoal.	Tar.	Crude Pyroligneous Acid.	Containing Actual Acid.	Gases.
Red Beech	slowly heated	26·7	5·9	45·8	5·2	21·7
	rapidly heated	21·9	4·9	39·5	3·9	53·8
Birch	slowly heated	29·2	5·5	45·6	5·6	19·7
	rapidly heated	21·5	3·2	39·7	4·4	35·6
Oak	slowly heated	34·7	3·7	44·5	4·1	17·2
	rapidly heated	27·7	3·2	42·0	3·4	27·0
Pine	slowly heated	30·3	4·4	41·0	2·7	24·4
	rapidly heated	24·2	9·8	42·0	2·4	24·1

This is the crude pyroligneous acid, sometimes called *pyroligneous vinegar.* It is a dark-brown liquid, having a strong smoky smell, and consists of acetic acid, diluted with more or less water, and holding in solution some creosote and empyreumatic oil, with pyroxylic spirit. It is from this crude acid that the U. S. and British acetic acid, corresponding to the acetic acid of commerce, is obtained. The purification is effected as follows. The acid is saturated with milk of lime, whereby calcium acetate is formed in solution, and thus most of the tarry matter is precipitated. The solution of calcium acetate is then mixed with a concentrated solution of sodium sulphate, and, by double decomposition, sodium acetate is formed in solution, and calcium sulphate precipitated. The solution of sodium acetate is next subjected to evaporation, during which further impurities that separate on the surface are skimmed off. The solution, being duly concentrated, is set aside to crystallize; and the impure salt thus obtained, after having been partially purified by solution and recrystallization, is fused in an iron vessel, stirred until it dries, and, the heat being carefully raised, subjected to incipient carbonization, whereby remaining empyreumatic matters are carbonized, with little damage to the salt. The mass is then dissolved in water, and the solution, being strained and recrystallized, furnishes pure sodium acetate. (See *Sodii Acetas.*) Finally, this salt, distilled with from 34 to 35 per cent. of its weight of sulphuric acid, yields the acetic acid of commerce, the residue being sodium sulphate, which is reserved for decomposing fresh portions of calcium acetate. The acid has still an empyreumatic flavor, which is removed by filtering it through animal charcoal or rectifying with potassium bichromate. The odor is due to *fur-*

furol, $C_5H_4O_2$, which, as Victor Meyer has shown, can be detected even in glacial acetic acid by the red coloration it gives with aniline. It may be removed from pyroligneous acid by agitating the liquid with 2 or 3 per cent. of benzene. The aqueous layer, after separation from the benzene, is stated to give by a single distillation a palatable table vinegar.

Acetic acid, according to Dr. Squibb, improves very much by age, and a sample examined for odor when freshly distilled would not be recognized as the same three months afterward.

An excellent quality of acetic acid is made by Dr. E. R. Squibb by an improvement on the process of Schwartz, the principal feature being the careful regulation of the heat, whereby the excessive charring of the wood is prevented and the formation of the tarry substances so reduced as to leave the acetic acid almost entirely free from empyreuma. The retorts, which are rectangular in shape, are supported by wheels secured to shafts, rotating in bearings connected with the sides, and are run upon car-tracks into the ovens, after they have been loaded with some billets of oak wood from the transfer car, in an ingenious and simple manner. In the construction of the ovens, care is taken to economize the fuel and to secure control of the temperature by the use of corrugated bottoms to the retorts and dampers in the flues; when necessary, the vapors are condensed in earthenware air condensers. Experience has shown that the production and liberation of acetic acid take place at a considerably lower temperature than that sufficient to convert the wood into charcoal, Dr. Squibb having proved that wood begins to char at 218·3° C. (425° F.); indeed, the wood which is removed from the retorts after the operation is over is sold as kindling-wood, and has the color of black walnut. The crude acetic acid does not require the tedious method of purification usually employed, but is treated with soda ash, forming sodium acetate, which is decomposed by sulphuric acid, and the acetic acid recovered in a purified condition by distillation.

The sp. gr. of the different acetic acids increases with their strength up to the density of 1·0748 (maximum), after which it decreases until it reaches 1·0553, the density of the strongest acid (*glacial acid*).

But it will be noticed upon an examination of the following table of Oudemans* that the specific gravity of the glacial (100 per cent.) and the 43 per cent. acid is practically the same, and that the 80, 79, 78, and 77 per cent. acids have exactly the same density, the variations between 67 and 89 per cent. being very slight. It will thus be seen that specific gravity cannot be relied upon as a criterion for strength. The glacial acid may, however, be distinguished from the 43 per cent. acid by adding 10 per cent. of water, when, if the density increases, the specimen is the stronger acid.

Percentage of Absolute Acetic Acid in Acetic Acid of Different Densities.

Temperature 15° C. (59° F.).

Per Ct.	Sp. Gr.	Per Ct.	Sp. Gr.	Per Ct.	Sp. Gr.	Per Ct.	Sp. Gr.	Per Ct.	Sp. Gr.

* Oudemans' more recent researches upon the specific gravities of acetic acid of varying strength are given in preference to Mohr's tables, used in previous editions of the U. S. Dispensatory, as it is believed that Mohr's experiments were conducted with an acid containing 5 per cent. of water. (Hoffmann, *Sammlung aller wichtigen Tabellen, Zahlen und Formeln*, p. 114.)

ACIDUM ACETICUM GLACIALE. *U.S., Br. Glacial Acetic Acid.* This acid, sometimes called *radical vinegar*, is a colorless, volatile, inflammable liquid, possessing a corrosive taste, and an acetous, pungent, and refreshing smell. It boils at 117° to 118° C. (242·6° to 244·4° F.). It crystallizes when cooled to 15·5° C. (60° F.), and remains crystalline until heated above 48° C. (*Br.*). It possesses the property of dissolving a number of substances, such as volatile and fixed oils (*P. J. Tr.*, Sept. 11, 1875), camphor, resins and gum resins, fibrin, albumen, etc. As it attracts humidity from the atmosphere, it should be preserved in well-stoppered bottles. Its combinations with salifiable bases are called acetates. "When the Acid is cooled to a temperature as near as possible to 15° C. (59° F.), but yet in a liquid form, its specific gravity should not be higher than 1·058, corresponding to at least 99 per cent. of absolute acid. At a temperature somewhat below 15° C. (59° F.), the Acid becomes a crystalline solid. When crystallized by cold, it becomes liquid again at about 15° C. (59° F.). Glacial Acetic Acid corresponds in properties to Acetic Acid (see *Acidum Aceticum*), and should respond to the same tests of purity; but the tint produced by the addition of 2 drops of potassium permanganate decinormal volumetric solution to 2 C.c. of the Acid diluted with 10 C.c. of water, contained in a clean, glass-stoppered vial, should not be changed to brown within two hours. To neutralize 3 Gm. of Glacial Acetic Acid should require not less than 49·5 C.c. of potassium hydrate volumetric solution (each C.c. corresponding to 2 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.* "It crystallizes when sufficiently cooled, and remains crystalline until the temperature rises above 60° F. (15·5° C.). Specific gravity 1·058, and this is increased by the addition of 10 per cent. of *water* (distinction from a diluted acid of 46 per cent., which has the same specific gravity). Each gramme diluted with 50 cubic centimetres of *water* should require for neutralization 16·6 cubic centimetres of the *volumetric solution of sodium hydroxide*. It must be free from the impurities indicated under 'Acidum Aceticum.'" *Br.* The anhydride has been isolated by C. Gerhardt, who finds it to be a limpid liquid, heavier than water, and having the constant boiling point of 138° C. (279° F.).*

Properties of the Acid of Commerce (*Acidum Aceticum*, U.S., Br.). "A clear, colorless liquid, having a strong, vinegar-like odor, a purely acid taste, and a strongly acid reaction. Specific gravity, about 1·048 at 15° C. (59° F.). Miscible with water or alcohol in all proportions. When heated, the acid is volatilized without leaving a residue." *U. S.*

"On adding to Acetic Acid enough ammonia water to neutralize it or to leave the Acid in slight excess, and then adding ferric chloride test-solution, the liquid will acquire a blood-red color, which is discharged by strongly acidulating with sulphuric acid. When the Acid is slightly supersaturated with ammonia, the liquid should not have a bluish tint (absence of *copper*), nor should any residue be left after evaporating the alkaline liquid on the water-bath (absence of *other fixed impurities*). Acetic Acid diluted with 20 volumes of water should neither become colored nor yield a precipitate with hydrogen sulphide test-solution (absence of *lead*, *copper*, etc.). Acetic Acid diluted with 10 volumes of water should not yield a precipitate or turbidity with barium chloride test-solution (absence of *sulphuric acid*), or with silver nitrate test-solution (absence of *hydrochloric acid*). If a portion of the Acid be just neutralized by ammonia, then mixed with some silver nitrate test-solution, and warmed, the liquid should not turn dark-colored or deposit a dark-colored precipitate (absence of *formic* or *sulphurous acid*). When the Acid is slightly supersaturated by sodium or potassium hydrate test-solution, the liquid should not have a smoky odor or taste. And if 5 drops of potassium permanganate decinormal volumetric solution be mixed with 2 C.c. of the Acid previously diluted with 10

* *Acidum Chloraceticum*, Chloracetic Acid. Three forms of this acid are known, mono-, di-, and tri-chloracetic acids, having the following formulas respectively, $C_2H_3ClO_2$, $C_2H_2Cl_2O_2$, and $C_2HCl_3O_2$. *Monochloracetic Acid* may be prepared by acting upon glacial acetic acid containing 10 per cent. of iodine with dry chlorine, reserving the portion distilling over between 180° C. and 188° C. *Dichloracetic Acid* distils over between 189° C. and 191° C. *Trichloracetic Acid*, discovered by Dumas in 1838, may be most conveniently prepared by treating chloral hydrate with three times its volume of fuming nitric acid, and placing the whole mixture in the sunlight until the red fumes have disappeared; the liquid is then distilled, and the portion coming over at 195° C. is pure trichloracetic acid. All the chloracetic acids are powerful caustics, destroying the epidermis. They form various salts, most of which are easily soluble in water. The mono- and tri- acids are solid, crystalline, deliquescent bodies; dichloracetic acid is a colorless liquid having a suffocating odor, and crystallizing at 0° C. Trichloracetic acid has been used as a caustic in practical medicine by Dumas, by Urner, by Sigmund, by Von Stein, and by Lanz. A small crystal placed on a *papilloma* is said to produce immediately a white, smooth, dry, adherent scurf, which falls off in a few days, leaving a rapidly-healing ulcer. The pain is said to be quite trifling, and may be entirely prevented by the previous use of a cocaine solution. *Vascular nævi* have also been destroyed; and Lanz affirms that in *obstinate gleet* cauterization with a 20-per-cent. solution is often most advantageous (*London Med. Rec.*, March, 1891). The acid has also been proposed as a test for albumen.

C.c. of water, and contained in a clean, glass-stoppered vial, the pink tint should not change at once to brown, but should change only gradually, and not become entirely brown, or free from pinkish brown, in less than half a minute (limit of *empyreumatic substances*). To neutralize 6 Gm. of Acetic Acid should require 36 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.* The British Pharmacopœia requires that "Each gramme should require for neutralization 5·5 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no residue on evaporation, and no characteristic reaction with the tests for lead, copper, arsenium, chlorides, nitrates, sulphates, and sulphites. It should not darken in color when exactly neutralized with *solution of ammonia* and warmed with *solution of silver nitrate* (absence of formates). 2 cubic centimetres of Acetic Acid diluted with 10 cubic centimetres of *water* should not immediately discharge the color of one drop of *solution of potassium permanganate*, but at the end of half a minute the mixture should retain a shade of crimson (limit of empyreumatic matter)."

Of the British acid (sp. gr. 1·044) the strength in hydrogen acetate is 33 per cent. The U. S. official acid is somewhat stronger than the British. In the arts *Acetic Acid No. 8* (sp. gr. 1·040) has long been used; it derives its name from the fact that one part added to sufficient water to make eight parts, by measure, constitutes so-called distilled vinegar used in pickling; the latter is not equal to the official diluted acetic acid in strength (one-fifth weaker). See *Acidum Aceticum Dilutum*, below. Calcium phosphate has been largely detected in acetic acid sold as pure, and was copiously precipitated by ammonia added in excess. (Bruckner, *A. J. P.*, Sept. 1870, p. 389.) Victor Meyer has met with glacial acetic acid contaminated with 0·108 Gm. furfurol in a litre. (*Ber. Chem. Ges.*, 1878, p. 1870.)

It is difficult to ascertain the strength of acetic acid by saturating it with the carbonated alkalies, when the operator depends upon test-paper for ascertaining the point of its neutralization. The difficulty is caused by the fact that the potassium and sodium acetates, though neutral in composition, are alkaline to test-paper. Hence the liquid begins to be alkaline to test-paper while some free acid yet remains, but insufficient to overcome the alkaline reaction of the salt formed. It follows, therefore, that by the use of test-paper the strength of the acetic acid will be underrated. The degree of inaccuracy, where test-paper is used, is much diminished by saturating the acetic acid with a solution of calcium saccharate of a known strength, as proposed by Mr. C. G. Williams. (*P. J. Tr.*, May, 1854, p. 594.) A still better way is to add to the acid a weighed excess of barium carbonate, and to calculate its strength by the amount of the carbonate decomposed, ascertained by deducting the undissolved from the total used. (*Redwood.*) Equally accurate results may be obtained by the use of calcium carbonate in a similar manner. (E. C. Nicholson and D. S. Price, *Chem. Gaz.*, Jan. 15, 1856.)

Charles F. Squibb has made numerous experiments proving the value of many strengths of acetic acid as menstrua for exhausting the valuable organic principles of drugs by percolation; he found even diluted acetic acid a reliable menstruum. J. P. Remington preferred a 10 per cent. acetic acid, and suggested a class of preparations termed "*acetracts*" to replace solid extracts. Acetic acid is a powerful solvent and can frequently be made to take the place of the more expensive alcoholic menstrua. (*A. J. P.*, 1897, p. 121.)

Uses of Crude Pyroligneous Acid. This acid having been incidentally described as the source of the acetic acid of commerce, it may be proper in this place to notice its uses. It has been employed as an application to *gangrene* and ill-conditioned *ulcers*. It acts on the principle of an antiseptic and stimulant; the former property being in part due to the presence of creosote.

The crude acid is advantageously applied to the preservation of animal food. Mr. William Ramsey made some interesting experiments with it for that purpose. Herrings and other fish, simply dipped in the acid and afterwards dried in the shade, were effectually preserved, and when eaten were found very agreeable to the taste. Herrings, slightly cured with salt by being sprinkled with it for six hours, then drained, next immersed in pyroligneous acid for a few seconds, and afterwards dried in the shade for two months, were found by Mr. Ramsey to be of fine quality and flavor. Fresh beef, dipped in the acid in summer for a minute, was perfectly sweet in the following spring. Professor Silliman states that one quart of the acid, added to the common pickle for a barrel of hams, at the time they are laid down, will impart to them the smoked flavor as perfectly as if they had been smoked in the ordinary way.

Acidum Aceticum Dilutum. *U. S.*, *Br.* *Diluted Acetic Acid.* "Acetic Acid *one hundred grammes* [or 3 fluidounces, 108 minims]; Distilled Water *five hundred grammes* [or 16 fluidounces,

435 minims]. To make *six hundred grammes* [or about 20 fluidounces]. Mix them. Specific gravity, about 1·008 at 15° C. (59° F.). It corresponds, in properties, to Acetic Acid (see *Acidum Aceticum*), and should respond to the same tests of purity. To neutralize 24 Gm. of Diluted Acetic Acid should require 24 C.c. of potassium hydrate volumetric solution (each C.c. corresponding to 0·25 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.*

"Acetic Acid, 2½ *fl. ounces* (more exactly, 2·49, Imperial measure) or 1137 *grains*, or 124·7 cubic centimetres or 130·2 grammes; Distilled Water, a sufficient quantity. Dilute the Acetic Acid with sufficient Distilled Water to form *one pint* (Imp. meas.) or one thousand cubic centimetres of Diluted Acetic Acid." *Br.* "Specific gravity, 1·006. Each gramme should require for neutralization 7·1 cubic centimetres of a *decinormal volumetric solution of sodium hydroxide*. It must be free from the impurities indicated under 'Acidum Aceticum.'" *Br.*

The object of having this preparation is to possess a weak solution of *pure* acetic acid which may be substituted for distilled vinegar in all formulas in which nicety is required. For a long period diluted acetic acid has been made by mixing one part of acetic acid with seven parts of water by measure. The official diluted acid was made considerably stronger in the U. S. P. 1880, and the strength has not been altered in the U. S. P. 1890. Distilled vinegar contains a little organic matter, which is always darkened or precipitated when its acid is saturated with an alkali, a change which does not take place when the diluted acetic acid is employed.

Medical Properties of Acetic Acid of Commerce (*Acidum Aceticum*, U. S., Br.). Acetic acid is very rarely used internally, but is refrigerant and astringent when sufficiently diluted. Owing to its volatility and pungency, its vapor is frequently applied to the nostrils as an excitant in *syncope*, *asphyxia*, and *headache*. When employed for this purpose, it is generally added to a small portion of potassium sulphate, so as to moisten the salt, and the mixture is put into small glass bottles with ground stoppers.*

It is a mild caustic, and has been used in cancer, by injection into the diseased tissue, but the general result has not been favorable. Two or three ounces of it taken internally undiluted very nearly caused death in an adult. (*Lancet*, July, 1867.) The prominent symptoms were, at first, slight collapse, and asphyxia from closure of the glottis. Recovery was secured by tracheotomy; after the reaction, great thirst, salivation, pain in the fauces, and inability to swallow, but without serious gastric, pulmonary, or cardiac disturbance, were present.

Medical Properties of the Glacial Acid. This acid is used only externally, and acts as a rubefacient, a vesicant, or a caustic, according to the length of time it is applied. Its application requires caution. It is sometimes employed as a substitute for cantharides, when a speedy blister is desired. It may be applied by means of blotting-paper or cambric moistened with the acid. It is a good corrosive for destroying *warts* and *corns*.

ACIDUM ARSENOSUM. U. S. (Br.) Arsenous Acid. [Arsenic Trioxide. White Arsenic.]

As_2O_3; 197·68. (ĂĢ'Ĭ-DŬM ĂR-SĒ-NŌ'SŬM.) As_2O_3; 197.8.

"Arsenious Anhydride, or arsenious oxide, As_4O_6, is obtained by roasting certain arsenical ores." *Br.*

Acidum Arseniosum, *Br.;* Arsenious Acid, Arsenicum Album, *Ed.;* Acidum Arsenicosum (*P. G.*); Arsenious Oxide, Arsenic, Arsenious Anhydride, White Arsenic; Acide arsénieux, Arsenic blanc, Fleurs d'Arsenic, *Fr.;* Arsenige Säure, Arsenichte Säure, Weisser Arsenik, *G.;* Arsenik, *Dan., Swed., Pol.;* Acido arsenioso, Arsenico, *It.;* Arsenico blanco, *Sp.*

Arsenous acid is prepared in Bohemia and Saxony, where it is procured on a large scale, as a collateral product, during the smelting of cobalt ores, which are almost invariably accompanied by arsenic, and in England from the mineral *arsenopyrite*, also called *mispickel* or *arsenical iron*, which is associated with the ores of tin and copper. The German process is that

* *Acidum Aceticum Camphoratum* (*Ed., Dub.*). *Camphorated Acetic Acid.* This is an old official remedy. It was prepared as follows. "Take of Camphor *one ounce* [av.]; Rectified Spirit *one fluidrachm;* Strong Acetic Acid *ten fluidounces*. Reduce the camphor to powder by means of the Spirit; then add the Acid, and dissolve." *Dub. Pharm.*

The use of the alcohol is simply to facilitate the pulverization of the camphor, and a few drops are sufficient. Acetic acid in its concentrated state readily dissolves camphor. In this preparation, the whole of the camphor is taken up by the acid. In consequence of the powerful chemical agency of the solution, and its extreme volatility, it should be kept in glass bottles accurately fitted with ground stoppers. Camphorated acetic acid is an exceedingly pungent perfume, which when snuffed up the nostrils produces a strongly excitant impression, and may be resorted to in fainting or nervous debility. It was an official substitute for Henry's *aromatic spirit of vinegar*.

A better *aromatic vinegar* is prepared by adding one and a half fluidrachms of best oil of rose geranium, and fifteen minims of oil of cloves, to four fluidounces of glacial acetic acid.

usually quoted as the older and better known. According to this, the ores are roasted in reverberatory furnaces with long horizontal flues. The arsenic is converted by combustion into arsenous acid, which rises in vapor and condenses on the sides of the flues. In this state it is impure, and requires a second sublimation, which is performed in cast-iron vessels, fitted with conical heads of the same material, having an opening at the summit. The vessels are placed over a furnace, and brought to a red heat, when a portion of the impure arsenous acid is thrown in through the opening, which is immediately stopped. This portion being sublimed, a second portion is introduced in a similar manner. Finally, the vessels are allowed to cool; and upon removing the heads the purified acid is found attached to them in vitreous layers, at first as transparent as glass, but gradually becoming, by contact with the air, opaque at their surface. These are broken into fragments of a convenient size, and thrown into commerce. The arsenous acid so obtained is generally packed in casks, containing from two to five hundred pounds, and is shipped principally from the ports of Hamburg and Bremen. The English process differs somewhat in its details, and essentially in its final product, which is fine and crystalline rather than amorphous. In this process the crude arsenic of the first sublimation is refined by introducing it into another furnace or series of furnaces, where it is again volatilized by the heat. When it condenses in the long series of chambers through which the vapors are carried, it is, if the process be fully successful, in the form of a perfectly white crystalline solid, which needs only to be ground and packed into kegs to be made ready for the market. The unground arsenic is, as stated, all in the *crystalline* condition, the temperature of the chambers being too low to allow of the formation of the glassy variety.

Properties. Arsenous acid is entirely volatilized by heat. As the German make of arsenic occurs in commerce, it is in masses, with a vitreous fracture, and of a milk-white color externally, but, internally, often perfectly transparent. As first sublimed, the whole mass is transparent; but it gradually becomes white and opaque, the change proceeding progressively from the surface inwards. This change has not been well explained, but probably depends upon the absorption of moisture, causing a gradual passage of the acid from the amorphous to the crystalline state. (*Pereira.*) Hence the masses "usually present a stratified appearance, caused by the presence, in separate layers, of the crystalline and opaque and of the amorphous and vitreous allotropic modifications of arsenious anhydride." *Br.* The U. S. Pharmacopœia, 1890, describes arsenous acid as follows: "Frequently the same piece has an opaque, white, outer crust enclosing the glassy variety within. Contact with moist air gradually changes the glassy into the white, opaque variety. Both are odorless and tasteless." According to Guibourt, the sp. gr. of the transparent variety is 3·73, of the opaque 3·69. The experiments, however, of Dr. J. K. Mitchell and Mr. Durand make the density of the former variety from 3·208 to 3·333. The English make of arsenic is always powdered, and, under a lens, is seen to consist of small crystals perfect in form, or of small fragments of larger crystals. In a poisoning case in 1880 (State of Conn. *vs.* Hayden) much was made to hinge upon the differences observed between this crystalline English arsenic and the commoner amorphous or German arsenic. (*Microscop. Exam. of Samples of Commercial Arsenic*, E. S. Dana. F. D. Linn & Co., Publishers, Jersey City, 1880.) As it occurs in the shops for medical use, it is often in the form of a white powder, almost as fine as flour. In this state it is sometimes adulterated with powdered lime or chalk, or calcium sulphate or arsenite, a fraud which is very easily detected by exposing the powder to a heat sufficient to evaporate the arsenous acid, when these impurities will be left behind. In consequence of the liability of the acid to contain impurities when in powder, it was directed in the U. S. Pharmacopœia of 1870 to be kept in masses, so that the apothecary may powder it for himself as it is wanted. It has been erroneously stated to have an acrid taste. Dr. Christison asserts that it possesses hardly any taste; inasmuch as it produces merely a faint sweetish impression on the palate. In strong, hot solution, it has an austere taste, most nearly resembling that of zinc sulphate. (*Mitchell* and *Durand.*) It has no smell, even in vapor; but when thrown on ignited charcoal it emits a garlicky odor, in consequence of its deoxidation, and the volatilization of the reduced metal. Its point of sublimation, according to Berzelius, is at an incipient red heat; but, according to Mitchell and Durand, it is lower than that of metallic arsenic, being only 218° C. (425° F.). In the British Pharmacopœia it is said to be entirely volatilized at a temperature not exceeding 204.4° C. (400° F.). Taylor gives the subliming point at 188° C. (370° F.); Wm. A. Guy states that arsenous acid rises in vapor at about 138° C. (280° F.). (*P. J. Tr.*, Feb. 1868.) When slowly sublimed, it condenses in regular octohedral crystals of a sparkling lustre.

It may also be obtained crystallized in fine octohedrals by the slow cooling of a solution of the acid in boiling diluted hydrochloric acid. (*Journ. de Pharm.*, 1873, p. 246.) "0·25 gramme, dissolved quickly in boiling *water* with five times its weight of *sodium bicarbonate*, should, after the cooled solution is well shaken with three successive drops of *hydrochloric acid*, discharge the color of 50·8 to 50·9 cubic centimetres of the *volumetric solution of iodine*." *Br.*

"In cold water both varieties dissolve very slowly, the glassy variety requiring about 30, the porcelain-like about 80 parts of water at 15° C. (59° F.). Both are slowly but completely soluble in 15 parts of boiling water. In alcohol, Arsenous Acid is but sparingly soluble, but it is soluble in about 5 parts of glycerin. Oil of turpentine dissolves only the glassy variety. Both varieties are freely soluble in hydrochloric acid, and in solutions of alkali hydrates and carbonates." *U. S.* "It is soluble in 100 parts of cold *water*, in 10 parts of boiling *water*, and in 5 parts of *glycerin;* it is moderately soluble in solutions of alkaline hydroxides and carbonates, in *hydrochloric acid*, and in mixtures of that acid and *water*." *Br.* The following is given on the authority of Bussy. The transparent acid dissolves much more rapidly than the opaque. By prolonged ebullition with water, the opaque variety attains the same solubility as the transparent, and may be supposed to be converted into the latter. Thus, at the boiling temperature, a pint of water dissolves 807 grains of either variety. The transparent variety, in cold saturated solution, gradually lessens in solubility, until it reaches the solubility of the opaque, no doubt in consequence of being changed into the latter. Pulverization lessens the solubility of the transparent variety, without affecting that of the opaque. The mixture of the two varieties of the acid in the same solution serves to explain the anomalies heretofore observed in its solubility. (*Journ. de Pharm.*, Nov. 1847.)* "When heated to 204·4° C. (400° F.), Arsenous Acid is completely volatilized without melting. When thrown on ignited charcoal, it emits an alliaceous odor. When its vapor is passed through red-hot charcoal, in an arsenic-tube, it is deoxidized, and metallic arsenic is deposited on the cooler portion of the tube as a mirror having a metallic lustre. An aqueous solution of Arsenous Acid has a faintly acid reaction upon litmus paper. Silver ammonium nitrate test-solution produces in the solution a lemon-yellow precipitate, which dissolves on addition of ammonia water; when this solution is heated, metallic silver is deposited (distinction from *arsenic acid*). Copper ammonium sulphate test-solution produces a bright green precipitate, which dissolves in ammonia water with a deep blue color. Hydrogen sulphide test-solution colors the solution of Arsenous Acid yellow; if a few drops of hydrochloric acid are added, it precipitates lemon-yellow arsenic trisulphide, which should be completely soluble in ammonium carbonate test-solution (absence of *antimony*, *tin*, and *cadmium*). When Arsenous Acid is carefully heated in a dry test-tube of hard glass, it should sublime without leaving a residue, and the sublimate should not at first show a yellow color (absence of *non-volatile matter* and of *arsenic sulphide*). If 1 part of Arsenous Acid be dissolved in 10 parts of ammonia water, with the aid of a gentle heat, the solution should neither leave an *insoluble residue*, nor show a yellow or other *color;* nor should the addition of a slight excess of hydrochloric acid produce a precipitate (absence of *metallic impurities*, *sulphides*, etc.). If 0·1 Gm. of Arsenous Acid be dissolved, together with 1 Gm. of sodium bicarbonate, in 20 C.c. of water by the aid of a gentle heat, it should decolorize not less than 20 C.c. of iodine decinormal volumetric solution (corresponding to at least 98·8 per cent. of Arsenic Trioxide)." *U. S.* "Its aqueous solution, which is odorless, tasteless, and faintly acid to *litmus*, gives with *solution of silver ammonio-nitrate* a canary-yellow precipitate readily dissolved by *solution of ammonia* and by *nitric acid*. Sprinkled on ignited charcoal, it emits an alliaceous odor. It is volatilized at 400° F. (204·4° C.). It should yield no characteristic reaction with the tests for lead, cadmium, antimony, tin, or sulphides. It should dissolve completely in *solution of ammonia*, and the resulting liquid when diluted with an equal volume of *water* and acidulated with *hydrochloric acid* should not have a yellow color (absence of arsenious sulphide)." *Br.*

Medical Properties. The official preparations of arsenic are all of them, when in sufficient concentration, violent irritants or escharotics.† Taken internally in sufficient dose they

* Experiments of M. L. A. Buchner on the solubility of arsenous acid in its various forms gave the following results. A liter of water saturated at 15° C. with crystallized arsenous acid contains gr. 2·821; with the amorphous and vitreous acid, gr. 9·306; while the same solutions, made by boiling and then allowed to cool for 24 hours, down to 15° C., contain of the crystallized acid gr. 27·839 per liter, and of the amorphous and vitreous, gr. 34·056 per liter. These results serve to confirm those of M. Bussy referred to in the text. (*Journ. de Pharm.* 1873, p. 247.)

† *Kakodylic acid*, a compound of arsenic, having the formula $AsO(CH_3)_2OH$, containing 54·35 per cent. of the metal, equivalent to 71·4 per cent. of the arsenous oxide, has been stated by various investigators to be free from

are exceedingly poisonous to both man and the lower animals. When properly administered they are alteratives, affecting in some unknown way the nutrition, especially of the nervous system. They are often of service in simple *nervous debility*, but are especially useful in *chorea* and in *chronic malaria*. When given for their tonic effect only, they should be used in doses so small as not to cause any general symptoms; but when a specific action, as in chorea, is desired, it is proper to begin with small doses and rapidly increase them until the limit of tolerance is reached. Not rarely, such doses produce gastro-intestinal irritation, especially pain and diarrhœa. To avoid this as much as possible, the remedy should be given after meals. When either gastro-intestinal irritation or the more peculiar effects of arsenic are caused, the dose should at once be lessened. The specific symptoms of *arsenicalism* are a general disposition to œdema, especially of the face and eyelids, a feeling of stiffness in these parts, itching of the skin, tenderness of the mouth, loss of appetite, and uneasiness and sickness of the stomach. The peculiar swelling produced is called *œdema arsenicalis*. In some instances the internal use of arsenic causes a rash not unlike that of measles, and, as in that affection, attended with catarrhal symptoms. (Tilbury Fox, *Med. T. and Gaz.*, March, 1868.) Sometimes salivation is produced, and occasionally the hair and nails fall off. It is stated by M. Charcot that he has seen, in two cases, decided anaphrodisiac effects from the prolonged use of arsenic, which disappeared several months after its discontinuance, and in one instance returned upon its resumption. (*Ann. de Thérap.*, 1865, p. 267.)

Arsenous acid has been exhibited in a great variety of diseases, the principal of which are *scirrhus* and *cancer*, especially cancer of the lip; anomalous *ulcers;* various *cutaneous diseases; intermittent fever; chorea; chronic rheumatism*, particularly those forms of it attended with pains in the bones; *rheumatic gout;* diseases of the bones, especially *nodes*, and firm swellings with deformity of the small joints of the hands; *chronic syphilitic affections; frontal neuralgia; hemicrania;* intermittent *neuralgic pains* of the stomach and bowels. In intermittent fever it is inferior only to Peruvian bark and its alkaloids; and probably no remedy surpasses or even equals it in *rheumatic gout*. In cutaneous affections, especially those of a scaly character, as *lepra* and *psoriasis*, it is an invaluable remedy. There would seem to be no objection against the very protracted use of this remedy in disease. Many years since, Tschudi drew attention to the so-called "*arsenic-eaters*" of Styria and the Tyrol. The habits of these people have been grossly exaggerated by some, whilst by others their existence has been denied, but the truth is that among the lower orders in the countries mentioned, there are many persons who habitually take small amounts of the poison. According to the report of a government commission, the dose of 0·62 grain is rarely exceeded. The "ratsbane-eaters" are said not to suffer in their health, and to be unusually strong and vigorous people.

The external application of arsenic has been principally restricted to *cancer*, and anomalous and malignant ulcers, especially of the kind denominated *noli me tangere*. Dupuytren used with advantage a powder composed of one part of arsenous acid and twenty-four parts of calomel, as a topical application to *herpes exedens*, and to the foul *ulcers* occurring after mercury.

Arsenic is the chief ingredient in nearly all the empirical remedies for the cure of *cancer* by external application. *Plunket's caustic*, a remedy of this kind of great celebrity, consisted of the *Ranunculus acris* and *Ranunculus flammula*, each an ounce, bruised and mixed with a drachm of arsenous acid and five scruples of sulphur. The whole was beaten into a paste, formed into balls, and dried in the sun. When used, these balls were rubbed up with yolk of egg, and spread on pig's bladder. The use of the vegetable matter is to destroy the cuticle; for, unless this is done, the arsenic will not act. In *onychia maligna*, Mr. Luke, of London, regarded an ointment composed of two grains of arsenous acid and an ounce of spermaceti ointment as almost a specific. (Pereira, *Mat. Med.*)

In Paris, an *arsenical paste* of the following composition has been used as an application to malignant *ulcers:*—red sulphide of mercury 70 parts; dragon's blood 22 parts; arsenous acid 8 parts. It is applied, made up into a paste with saliva. The pain produced by this composition is very severe, and its application dangerous. The *arsenical paste of Frère Côme*

poisonous properties, whilst in the hands of others it has appeared to be an active toxic agent. A very elaborate research made by Drs. John Marshall and Howard Green (*Amer. Chem. Journ.*, May, 1886) appears to have settled the question. It was first found that kakodylic acid of American commerce produces in rabbits symptoms similar to those caused by arsenous acid, although in a very mild degree. Analysis, however, showed that this kakodylic acid contains free arsenous acid. Chemically pure kakodylic acid was then used. When introduced into the stomach in repeated doses of seven grains it caused in the lower animals vomiting and diarrhœa, profuse salivation, staggering, weakness, and death in one instance. Kakodylic acid may be looked upon as a very mild arsenical preparation. It has been highly recommended by Danlos in *psoriasis*, four grains three times a day. Balzer and Griffon have recorded cases in which eight grains a day caused extensive desquamative erythema.

has been applied advantageously by M. Biett to the ulcerated surfaces in *yaws*. The precaution was used of not applying it, at one time, over a surface larger than that of half a dollar. This paste is made by mixing water with a powder consisting of ten grains of arsenous acid, two scruples of red sulphide of mercury, and ten grains of powdered animal charcoal. The practice of sprinkling unmixed arsenous acid on ulcers is fraught with the greatest danger. Mr. S. Cooper characterizes it as a murderous practice.

Febure's remedy for cancer consisted of ten grains of arsenous acid, dissolved in a pint of distilled water, to which were added an ounce of extract of conium, three fluidounces of solution of lead subacetate, and a fluidrachm of tincture of opium. With this the cancer was washed every morning. Febure's formula for internal exhibition was, arsenous acid two grains, rhubarb half an ounce, syrup of chicory q. s., distilled water sufficient to make a pint. Of this mixture, a tablespoonful, containing about the sixteenth of a grain of the acid, was given every night and morning. The dose was gradually increased to six tablespoonfuls.

Arsenous acid may be given in doses of from one-thirtieth to one-twentieth of a grain (0·002 to 0·003 Gm.), three times a day, in the form of pill. It is usually combined with opium, which enables the stomach to bear the medicine better. The *Asiatic pills*, so called, consist of arsenous acid and black pepper, in the proportion of 1 part of the former to 80 parts of the latter. A preparation much used on the continent of Europe is *Boudin's solution*, which is simply an aqueous solution of arsenous acid with the addition of wine, and is made by boiling one gramme (15·4 grains) of the acid with one liter (2·1 pints) of distilled water till entirely dissolved, then cooling, filtering, adding enough distilled water to supply the loss, and finally mixing with one liter of white wine. Of this solution a fluidounce contains about one-quarter of a grain of arsenous acid.

Properties of Arsenous Acid as a Poison. Arsenous acid, in an overdose, whether internally or externally, acts with very great energy, and generally destroys life in a short time; but in rare instances no well-marked symptoms have been developed until eight or nine hours after the ingestion of the poison. Dr. Edward Hartshorne relates a case of recovery in which at least a drachm of arsenous acid had been swallowed, and where the symptoms of poisoning were delayed for sixteen hours. (*Med. Examiner*, 1855, p. 707.) The symptoms produced by the poison are—an austere taste; fetid state of the mouth; frequent ptyalism; continual hawking; constriction of the pharynx and œsophagus; the sensation of the teeth being on edge, hiccough; nausea; anxiety; frequent sinkings; burning pain at the præcordia; inflammation of the lips, tongue, palate, throat, bronchi, and œsophagus; irritable stomach, so as not to be able to support the blandest drinks; vomiting of matters, sometimes brown, at other times bloody; profuse serous or bloody stools; small, frequent, and irregular pulse, but occasionally slow and unequal; palpitations; syncope; insatiable thirst; burning heat over the whole body, or a sensation of icy coldness; difficult respiration; cold sweats; suppression of urine, or scanty, red, bloody, and sometimes albuminous urine; change in the countenance; a livid circle round the eyelids; swelling and itching of the body; livid spots over the surface, and occasionally a miliary eruption; prostration of strength; loss of feeling, especially in the feet and hands; delirium; convulsions, often accompanied with insupportable priapism; falling off of the hair, detachment of the cuticle, etc. In some cases there is inflammation with burning pain in the urino-genital organs. It is very rare to observe all these symptoms in the same individual. Sometimes, indeed, they are nearly all wanting, death taking place without any pain or prominent symptom. Occasionally the phenomena have a perfect resemblance to those of Asiatic cholera in the stage of collapse. In rare cases stupor is a very prominent symptom; and the diarrhœa may not be pronounced. After death, the morbid appearances are various. In some instances no vestige of lesion can be discovered. The appearances, however, in the generality of cases, are the following. The mouth, stomach, and intestines are inflamed; the stomach and duodenum exhibit spots resembling eschars, and perforations of all their coats; and the villous coat of the former is in a manner destroyed, and reduced to the consistence of a reddish-brown pulp. Wide-spread fatty degeneration has also been noted. In cases of recovery, it has been a question how long it takes for the poison to be eliminated from the system. In an instance, reported by Dr. D. Maclagan, in which about two drachms of the poison had been swallowed, and in which magnesia was used successfully as an antidote, arsenic was detected in the urine by Marsh's test as late as the twentieth day.

A milder grade of arsenical poisoning, yet sometimes serious in its consequences, has resulted in many instances from the inhalation of the air of apartments lined with green wall-paper, which owes its color to copper arsenite, and from which a fine poisonous dust sometimes

escapes when the paper has not been well prepared. (See *Chem. News*, March 24, 1860.) The burning of green tapers is sometimes attended with an arsenical odor; and chemical examination has shown that, though in relatively rare instances, they do contain arsenous acid in injurious quantities. (*Lancet*, 1873, p. 715.) Death has also resulted, in more than one instance, from working in the manufacture of green artificial leaves. (*Chem. News*, Nov. 30, 1861.) Ulceration of the anus has resulted from the habitual use of green paper.

In view of the numerous accidents and crimes caused by the use of arsenous acid, its sale should be regulated by law in all the States of the Union. In 1851 an act for this purpose was passed by the British Parliament.

There can be no doubt that, when applied to any ulcerated surface, arsenic may be absorbed with fatal result; death has indeed occurred in a number of cases from the use of arsenic as an escharotic to tumors, cancerous ulcers, etc. As indicated by Mr. Blackader, absorption is less apt to follow the use of large than of small quantities; the larger amount probably killing the part to which it is applied, and thereby preventing absorption. If this dangerous caustic be used at all, it should be in accordance with these facts. Harles's observations also seem to show that when the surface is that of a chronic ulcer, either simple or malignant, absorption is less prone to occur than from a fresh wound.

Treatment of Poisoning by Arsenous Acid. If the antidote be not directly at hand, free vomiting should be induced by the finger, the feather part of a quill, and the administration of an emetic. The same object is promoted by the use of the stomach-pump. Demulcent drinks should be freely given, such as milk, white of eggs and water, or flour and water, which serve to encourage the vomiting and to envelop the poison.

The antidote having been faithfully applied, the subsequent treatment consists in the administration of mucilaginous drinks, and the treatment of symptoms as they arise. Convalescence is generally long and distressing: usually dyspeptic symptoms mark the presence of gastro-intestinal inflammation or even ulceration, whilst not rarely violent neuralgic pains, with loss of power, wasting of the muscle, and other trophic changes, show that a peripheral neuritis has been produced; and hence it is of the greatest importance to attend to the diet, which should consist exclusively of milk, gruel, cream, rice, and similar bland articles.

The antidote above referred to is *ferric hydrate*, in the *moist* or *pulpy* state. As soon as it is ready, it must be given in doses of a tablespoonful to an adult, of a dessertspoonful to a child, every five or ten minutes, until the urgent symptoms are relieved. It is calculated that the quantity taken should be at least twelve times the supposed amount of the poison swallowed; but, as the antidote is perfectly innocent, it is prudent to give it in larger quantities. According to the experiments of E. Riegel, one part of arsenous acid in solution is so fully precipitated by ten parts of the dry oxide, that, after its action, not a trace of the poison can be detected, even by Marsh's test. Its efficacy is of course greater the sooner it is administered after the ingestion of the poison; but even after delay its use will prove advantageous, so long as any portion of the poison still remains in the stomach. The antidote acts by producing with the poison, by a transfer of oxygen from the oxide to the acid, an insoluble, and therefore inert, ferrous arsenate $2(Fe_2(OH)_6) + As_2O_3 = Fe_3(AsO_4)_2 + 5H_2O + Fe(OH)_2$. This antidote for arsenous acid was discovered by Drs. Bunsen and Berthold, of Göttingen, in 1834; and its efficacy has been abundantly confirmed by experiments on inferior animals, and by its successful application to numerous cases of poisoning in the human subject. Various observations have been made as to the best forms of the oxide for use, but as long ago as 1842 Prof. William Procter (*A. J. P.*, xiv. 29) proved that the hydrate gradually decreases in its power of neutralizing arsenous acid the longer it is kept, and that this decrease in power is more rapid when it is mixed with much water than when in the form of a thick magma. The cause of this diminution of neutralizing power, by being kept, is explained by the experiments of G. C. Wittstein. This chemist finds that ferric hydrate, recently precipitated, dissolves readily in acetic and other vegetable acids in the cold, but becomes nearly insoluble when kept for some time under water. It should be an invariable rule to prepare the antidote at the time it is wanted from materials always kept at hand. A very efficient antidote may be made by precipitating the tincture of the chloride of iron with sodium bicarbonate.

Dialyzed iron has been frequently suggested as an antidote for arsenic (*Phila. Med. Times*, Dec. 8, 1877; *A. J. P.*, Jan. 1878), especially if its administration be followed by a dose of common salt, which precipitates the ferric hydrate in the stomach; but Edward Hirschsohn (Dorpat, Russia) cautions against the use of dialyzed iron, because his experiments show that the resulting combination parts with its arsenic in the presence of acids much more readily

than does the *Antidotum Arsenici* of the Russian Pharmacopœia—made by diluting one ounce of solution of ferric sulphate (Monsel's solution) with four fluidounces of water, then adding a mixture of three drachms of calcined magnesia with four fluidounces of water. (See *Ferri Oxidum Hydratum cum Magnesia.*)

Dr. Köhler, of Halle, believes that saccharine oxide of iron in solution is preferable to all other preparations, in poisoning by arsenous acid. This forms, like the hydrated powder, an insoluble compound with the acid. He bases his opinion upon experiments with the lower animals, and gives the details of a case in which it proved successful in the human subject after the swallowing of more than half a drachm of the acid in powder. He gave a large teaspoonful of the saccharine oxide with a drachm of water immediately afterwards, which was repeated every 15 minutes for two hours, followed by an emetic dose of ipecacuanha, and then repeated every half-hour. The patient recovered. (*Br. and F. Med.-Chir. Rev.*, 1870.)

Bussy has proposed light magnesia, or the kind which has not been too strongly calcined, as well as recently precipitated gelatinous magnesia, as an antidote for arsenous acid; and a case is given by him in which it appeared to prove efficacious. (*Journ. de Pharm.*, x. 81.) The dense kind has very little efficacy. Dr. Christison saw a case in which this antidote seemed very serviceable. A successful case is also reported by Cadet de Gassicourt (*Journ. de Pharm.*, Mars, 1848), and another by Dr. E. Bissell, of Norwalk, Conn. (*Am. Journ. of Med. Sci.*, July, 1848). For the full precipitation of arsenous acid, eighteen times its weight of anhydrous magnesia are required. (*E. Riegel.*) Like the ferric hydrate, the magnesian antidote is most conveniently kept, in a pulpy state, under water in stopped bottles. M. Schroff has made some experiments on rabbits, to determine the comparative efficacy, as antidotes, of the ferric hydrate and magnesia, and gives the preference to the latter. The hydrated magnesia is best prepared extemporaneously by quickly forming a solution of magnesium sulphate, and precipitating this by ammonia water, which is preferable to potassa, as any portion of the latter, remaining in the preparation, might act injuriously by favoring the solubility of the arsenous acid. Notwithstanding these statements, however, it is asserted by T. and H. Smith, of Edinburgh, on the basis of experiment, that magnesia is incapable of neutralizing arsenous acid, and is utterly useless as an antidote (*Pharm. Journ.*, 1865, p. 144), and that it would be unwarrantable to rely on it when the ferruginous antidote is attainable. Probably the best antidote known is the combination of ferric hydrate with magnesia, now recognized by the U. S. Pharmacopœia.

Reagents for detecting Arsenous Acid. As arsenic is so frequently employed for criminal purposes, it becomes important to detect its presence in medico-legal investigations. The tests for it may be divided into those which indicate indirectly its presence, and those which demonstrate its presence incontestably, by bringing it to the metallic state. The former embrace all the liquid reagents so called; the latter, the processes for metallization. It is necessary, however, to be aware of the fact that many of the substances employed as tests for arsenic are themselves often contaminated with arsenic, and unless great care be exercised to select reagents perfectly free from this impurity, there will be danger that the results may be fallacious.

The most characteristic reagents are *hydrogen sulphide*, *ammoniacal silver nitrate*, and *ammoniacal copper sulphate*. In the opinion of Dr. Christison, the concurrent indications of these three tests are all-sufficient for detecting arsenous acid; but we think that in questions involving life the metallization of the poison should never be omitted.

In using hydrogen sulphide, the solution must be neutral or slightly acid. An excess of alkali may be neutralized with acetic acid, and an excess of nitric or sulphuric acid by potassa. A slight excess of acetic acid is not hurtful, but rather favors the subsidence of the precipitate, which is the arsenic tersulphide, and is soluble in ammonia, ammonium carbonate, and potassium bisulphate, and gives, moreover, a metallic sublimate when heated in a tube with reducing agents, as described below. According to Dr. Christison, this test is so exceedingly delicate that it detects the poison when dissolved in one hundred thousand parts of water. The color it produces is lemon- or sulphur-yellow; but the presence of vegetable or animal matter commonly gives it a whitish or brownish tint. If yellow, it might be mistaken for tin sulphide or cadmium sulphide, which are also yellow, but the latter is quite insoluble in ammonia, while the former gives no metallic sublimate when heated with reducing agents. If it be brownish, it may still contain arsenic, but must first be freed from organic matter.

The ammoniacal silver nitrate gives a yellow precipitate of silver arsenite, readily soluble to a clear solution in ammonia and in nitric or acetic acid.

The ammoniacal copper sulphate is a test of very great delicacy. The precipitate occasioned by it is the copper arsenite, of an apple-green or grass-green color. Its operation is prevented

by hydrochloric, nitric, sulphuric, acetic, citric, and tartaric acids in excess; as also by ammonia.

Of the three tests mentioned, perhaps hydrogen sulphide is the most delicate; and it has the advantage of yielding a precipitate eligible for subsequent reduction. But they are all liable to the objection of being obscured in their indications, where the amount of poison is small, by the presence of organic matter; a complication constituting the most difficult problem for the medical jurist. As this case includes all others of more easy solution, we shall suppose it to occur, and shall indicate the steps to be pursued.

Having obtained general indications of the presence of arsenic, the first step will be to separate the organic matters; the second, to throw down the arsenic by means of the hydrogen sulphide; and the third, to reduce the precipitate obtained to the metallic state. It is proper to state here that, in a communication to the Paris Academy, Dr. Blondlot, of Nancy, asserts, as the result of numerous experiments, that the smallest quantity of oily or fatty matter has the effect of diminishing, even to one-twentieth, the solubility of arsenous acid, and consequently of very much increasing the difficulty of detecting it. (See *A. J. P.*, 1860, p. 220.)

The following are the directions given by Prof. Wormley (*Micro-Chemistry of Poisons*, 2d ed., p. 299) for separating the organic principles. After the addition of water, if necessary, the mass is intimately mixed with about one-eighth of its volume of pure hydrochloric acid, and maintained at near the boiling temperature until the organic solids are entirely disintegrated. The mixture is then allowed to cool, transferred to a clean muslin strainer, and the matters retained by the strainer washed with water; the strainer with its contents may be reserved for future examination. The strained liquid is concentrated at a moderate heat if necessary, allowed to cool, and again filtered.

A given portion of the filtrate thus obtained is examined by the method of Reinsch (see page 29), successive slips of the copper being added as long as they receive a deposit. Any pieces of the metal that have thus become coated, after being thoroughly washed and dried, are heated in a suitable reduction tube, and the result examined in the usual manner. Another portion, or the whole, of the remaining filtrate may be exposed for several hours to a slow stream of the hydrogen sulphide gas, then gently warmed, and allowed to stand until the supernatant liquid has become perfectly clear. The precipitate thus produced is collected upon a small filter, washed, and, while still moist, digested with pure water of ammonia; this liquid will readily dissolve any arsenic sulphide present, whilst the organic matter may remain undissolved. The ammoniacal solution is filtered, and the filtrate carefully evaporated at a moderate heat to dryness. Should the residue contain organic matter and only a minute quantity of the sulphide, it may require further purification before its arsenical nature can be determined.

If, however, it be moderately pure arsenic sulphide, it may be at once reduced to the metallic state, which can be accomplished by the method of Fresenius. The sulphide is mixed with sodium carbonate and potassium cyanide, and the mixture placed in the wide part of a tube of hard German glass drawn out at one end to capillary fineness. Carbonic anhydride properly dried is then passed through the tube, and the portion containing the mixture heated to redness; in this way the arsenical sulphide is reduced and the metal condensed in the capillary portion, where the smallest quantity can be recognized.

Dr. E. Davy, of Dublin, has recommended (*Chem. News.*, vol. iii. p. 288) potassium ferrocyanide previously dried at 100° C. (212° F.) as a substitute for the potassium cyanide. It has the advantage over the latter that it does not readily absorb moisture from the atmosphere.

In order to facilitate the detection of arsenic in the solid tissues, as the liver, spleen, stomach, etc., it is necessary first to destroy the animal matter, and then to dissolve out the poison. Various agencies have been resorted to for this purpose, but the method of Fresenius and Babo is generally accepted as the best. According to this, the finely divided fragments of solid matter are heated with pure hydrochloric acid, and potassium chlorate is added from time to time until the mass becomes homogeneous and of a light yellow color. It is then heated until the odor of chlorine has disappeared. After filtration any arsenic present will exist in the filtrate as arsenic acid. This is reduced by sulphurous acid gas or a solution of sodium bisulphite, so that the arsenic is brought to the condition of arsenous acid, in which condition it is more readily acted upon by hydrogen sulphide gas.

After thorough precipitation of the sulphide and purification of this precipitate by treatment with ammonia as already described, if the residue from the evaporation of the ammonia still contain organic matter mixed with the arsenous sulphide, it is best purified as follows. Treat the residue with a small quantity of concentrated nitric acid, and evaporate the mixture again

to dryness, this operation with nitric acid being repeated, if necessary, until the moist residue has a yellow color. The residue is then moistened with a few drops of a concentrated solution of caustic soda, a small quantity of pure powdered sodium carbonate and sodium nitrate added, and the well-mixed mass cautiously evaporated to dryness; the heat is then very gradually increased until the mass becomes colorless, when the organic matter will have been entirely destroyed. The nitric acid and the soda compounds employed should be free from chlorine, or a portion of the arsenic may be volatilized as chloride. (Wormley, *Micro-Chemistry of Poisons*, 2d ed., p. 303.)

Another method of separating arsenic in solution from organic matters, now frequently employed, is by the process of dialysis, invented by Prof. Graham. (See *Dialysis.*) By means of an instrument called the dialyser, watery solutions of saline and other crystallizable substances may be separated from those not crystallizable, such as gelatinous, albuminous, mucilaginous, and amylaceous liquids, the latter refusing to pass through a diaphragm of some porous substance, which is readily permeable by the former. Thus, a circular piece of parchment paper, folded in the form of a common filter, is placed in a vessel containing distilled water; the suspected liquid, having been heated so as to effect a more complete solution of the arsenic, is poured into the filter, and the vessel set aside for twenty-four hours. At the end of this time, the crystallizable matter, including the arsenic, will have, to a great extent, passed through into the distilled water, leaving the organic matters behind, and a solution will have been obtained in a condition fit for the application of the different tests.

The passage of the arsenic through the membrane is, however, rarely a complete one, and the test cannot allow us to dispense with more thorough methods of examination.

Following up a suggestion of Dr. Clarke, of Aberdeen, that arsenic might be separated by taking advantage of the volatility of its chloride, Dr. Andrew Fyfe, of the same place, applied the principle to the detection of the metal when mixed with organic matter. For this purpose, he heated the arsenical liquid with sulphuric acid, free from arsenous acid, in a flask to which a bent tube and cooled receiver were adapted. When the mixture was brought to the boiling point, a little dried sea-salt was added, the receiver was connected, and the distillation continued for some time. Hydrochloric acid was evolved, which, by reacting with the arsenous acid, produced arsenic terchloride, which distilled over free from organic matter. The arsenic terchloride was then precipitated by a stream of hydrogen sulphide gas to obtain the yellow arsenic tersulphide, or subjected to the action of Marsh's test. (*Philos. Mag.*, 4th series, ii. 487.) By keeping present a larger amount of salt than can be decomposed by the sulphuric acid, the formation of sulphurous acid is avoided, and no danger is run of converting arsenous acid into the arsenic compound, as is the case in the presence of free chlorine. Arsenic acid is not converted into a volatile chloride, and would therefore escape detection in this process. Indeed, it is proposed to distinguish between arsenous and arsenic acids in mixtures by this reaction. After all the arsenous acid has been distilled off as arsenous chloride, the arsenic acid can be reduced by sulphurous acid and then distilled for itself. (*Handwörterbuch der Chem.*, i. 746.) The reduction of arsenic acid to arsenous acid is very conveniently effected, according to E. Fischer, by ferrous chloride used in connection with hydrochloric acid. (*Ber. der Chem. Gesellschaft*, xiii. 1778.) Dr. Penny and Mr. W. Wallace bear testimony to the value of the plan of converting the arsenic into terchloride, as a means of separating the metal from organic matter, but think it will be found more convenient to produce the terchloride by the direct agency of hydrochloric acid than by sulphuric acid and sodium chloride as recommended by Dr. Fyfe.

One formula for reduction, that of Fresenius, has been given. Still another method, and one in which the whole process from beginning to end may take place in a single tube, is the following. The sulphide is mixed with sodium oxalate (a salt which contains no water of crystallization), and the dry mixture is transferred to a suitable tube sealed at one end. An arsenical mirror is readily obtained, and if the heat is continued long enough no arsenic remains behind—an excellent and easy method, in which the reducing gas is carbonic oxide, in an atmosphere of carbonic anhydride. (Blyth, *Poisons, Effects and Detection*, p. 542.) If any doubt be felt as to the nature of the crust, it may be driven up and down the tube, so as to convert it into sparkling octohedral crystals of arsenous acid, the triangular facets of which may be seen with a magnifying glass. Finally, the crystals may be dissolved in a drop or two of distilled water, and the solution will react characteristically with the liquid tests.

Another method of testing for arsenic was proposed by Mr. Marsh, and is perhaps the best known of the arsenic tests. It consists in taking advantage of the power, which nascent

hydrogen possesses, of decomposing the acids of arsenic, with the result of forming water and arsenuretted hydrogen, as illustrated by the subjoined reaction:

$$As_2O_3 + (H_2)_6 = (H_3As)_2 + (H_2O)_3.$$

The liquid from the stomach, or obtained from its contents by boiling water, is added to the materials for generating hydrogen (pure dilute sulphuric acid and zinc), contained in a self-regulating generator of hydrogen. Dr. Canudas y Salva prevents the possible explosion of the apparatus, resulting from the ignition of the hydrogen before all the air has been expelled, by placing in the lateral exit tube two metallic meshes, enclosing between them very loose cotton. (*N. R.*, April, 1878.) Fresenius proposed the same years ago. If the liquid from the stomach contain arsenic, the nascent hydrogen will combine with the metal, and the nature of the compound gas formed may be ascertained by burning a jet of it from a fine jet-pipe connected with the generator. The flame will have a characteristic blue color; and, by holding a porcelain plate against it, a thin film of metallic arsenic,* forming a black stain, will be deposited. Liebig and Mohr bear testimony to the delicacy of this test; but to remove every source of fallacy it is necessary to be sure of the purity of the materials for generating the hydrogen by a preliminary trial of the gas before the suspected liquid is added; as zinc and sulphuric acid are both liable to contain arsenic. This trial is made by holding a plate against the burning hydrogen, which, if pure, will produce no stain. The pieces of zinc employed should be changed after every experiment. Magnesium or aluminum may be advantageously substituted for zinc, as they contain no arsenic, or, still better, sodium amalgam (made by adding about 5 per cent. of metallic sodium to some warmed mercury), as proposed by E. W. Davy. This can be used then in a neutral solution, the evolution of nascent hydrogen being due to the decomposition of the water by the sodium.

If the sulphuric acid used to act upon the zinc contains nitrous compounds, the liberation of arsine may be prevented. To obviate this difficulty a solution of stannous chloride in hydrochloric acid should be added towards the end of the operation. This liberates any arsenic present because of its reducing action, and arsine will be formed from it.

Still another modification is Fleitmann's test, in which the use of zinc, magnesium, or aluminum is retained, but the development of nascent hydrogen is brought about by the addition of caustic potassa or soda. Under these circumstances arseniuretted hydrogen is produced, but antimoniuretted hydrogen cannot be formed. A modification of Marsh's apparatus consists in having the tube which delivers the hydrogen arsenide narrowed in several places. If, then, while the gas is passing, heat be applied a little this side of the narrowed place, the compound is decomposed and a bright mirror of metallic arsenic is deposited in the contraction. As ever so small a deposit can be changed subsequently into oxide or sulphide, both of which are characteristic, this test is quite delicate.

It has been objected to Marsh's test, that antimony forms a compound with hydrogen, very similar to arseniuretted hydrogen, both in the color of its flame, and in the metallic spot which it deposits during combustion on cold surfaces. Still, the two metals may be distinguished by acting on the metallic spot with a drop or two of fuming nitric acid, with the aid of heat. Arsenic will thus be converted into soluble arsenic acid, precipitable brick-red by nitrate of silver; antimony, on the other hand, into insoluble antimonic acid. Another way of distinguishing them is to apply to the stain a solution of sodium hypochlorite, which instantly dissolves the arsenical spot, without affecting that of antimony, or solution of stannous chloride, which has no action on metallic arsenic, while it dissolves slowly but completely the antimony stain. (Blyth, *Poisons, Effects and Detection*, p. 526.) Sodium nitroprusside also, while it has no effect upon arsenic spots, will dissolve those of antimony completely and easily. (*Handwörterbuch der Chem.*, i. 757.) In case the metallic mirror is obtained in the tube by Berzelius's modification of Marsh's test, a stream of hydrogen sulphide may be passed, whilst immediately behind the stain a gentle heat is applied. Arsenic is changed thereby to yellow sulphide, while antimony produces an orange or black sulphide; if dry hydrochloric acid gas is now transmitted, the arsenical sulphide is unchanged, while antimony sulphide is converted into chloride of antimony, which volatilizes without the application of heat. (Blyth, *loc. cit.*) Ammonium sulphide dissolves the arsenical spot with difficulty, leaving on evaporation a yellow stain; it readily dissolves the antimonial, and yields an orange-red spot. Marsh's test may be still further modified as proposed by Lassaigne. The current of hydrogen arsenide

* Retgers (*Pharm. Centralh.*, 1894, 445) believes that the spots on the porcelain are not metallic arsenic, but arseniuretted hydrogen in the solid state, of the formula AsH.

is conducted into solution of silver nitrate, when it is decomposed according to the reaction

$$AsH_3 + (AgNO_3)_6 + (H_2O)_3 = H_3AsO_3 + (HNO_3)_6 + (Ag_2)_3.$$

Here arsenous acid is formed, which goes into solution, and metallic silver separates out. Hydrogen antimonide passed into silver nitrate solution gives a black precipitate of silver antimonide, in which all the antimony is contained.

Gutzeit's modification of this test is to carry out the reaction in a test-tube, which is then covered by paper moistened with silver nitrate. A black stain indicates the presence of arsenic. Ritsert (*Pharm. Zeit.*, 1889, 368) has increased the delicacy of this by using ammoniacal silver nitrate. It is asserted that 0·0005 milligramme of arsenous oxide will cause a brown stain.

Professor Reinsch has proposed a method for detecting arsenic in organic liquids, which is extremely delicate and at the same time has the merits of facility and celerity. It consists in acidulating the suspected liquid with hydrochloric acid, which converts the arsenous acid into the terchloride, and boiling in it, for ten minutes, a slip of copper foil, on which the arsenic is deposited as an alloy consisting of one part arsenic to five parts copper; and then separating it in the state of arsenous acid, by subjecting the copper, cut into small pieces, to a low red heat in the bottom of a small glass tube. The peculiar crystalline appearance of arsenous acid, mentioned in the preceding page, is conclusive of its presence; and, besides, if collected and dissolved in water it will answer to the ordinary tests for the poison. The merit of Reinsch's procedure is not so much that it gives a characteristic deposit on the copper—for bismuth, tin, zinc, and antimony also give deposits—as that the copper collects all the arsenic from the organic liquid, and presents it in a convenient form for applying the liquid and subliming tests. But Reinsch's method is not without its fallacies. Thus, it has been ascertained that the presence of a nitrate or chlorate in the suspected material prevents the characteristic action of the arsenic on the copper until the whole of these substances have been consumed by reaction with the metal. Besides, both hydrochloric acid and copper are liable to contain arsenic, and therefore to afford fallacious results. This, however, is less true of the hydrochloric acid prepared in this country than of the European, as the sulphuric acid employed in its preparation is obtained generally from native sulphur, instead of from pyrites as abroad. Nevertheless, no conclusion from Reinsch's test can be certainly relied on unless the hydrochloric acid has been ascertained to be free from arsenic. With the copper there is less risk, as the arsenic in it can act only by solution of the copper itself, and this is known by the green color imparted to the liquid; so that, if the arsenical deposit should be produced without discoloration of the liquid, the indication of the presence of the poison may be considered as satisfactory. (*Odling* and *Taylor.*)

If the process of Reinsch is to be applied to the arsenic sulphide, it will be necessary to bring this into the liquid form. For this purpose Prof. J. C. Draper, of New York, makes use of ammonia, which dissolves the sulphide, and is also capable of attacking copper. The substance supposed to contain the sulphide, having been covered, in a suitable vessel, with water of ammonia, is set aside in a warm place, and permitted to stand for a few hours. The solution of the sulphide is then separated by filtration, strips of clean, bright copper are introduced into it, and the whole is gently heated. The copper gradually becomes coated with a deposit like that which is formed in Reinsch's process. (*N. Y. Med. Journ.*, 1865, p. 13.)

The power of hypophosphites to reduce arsenical solutions, precipitating metallic arsenic, has also been proposed as the basis of a test. In sensitiveness it is said to rank between the tests of Gutzeit and Bettendorff. (*Apotheker Zeit.*, 1890, p. 263.)

Still another method of detecting arsenic is the *electrolytic*, consisting in exposing the suspected liquid, in connection with diluted sulphuric acid, to a voltaic current, through the influence of which, if arsenic be present, even though associated with large quantities of organic matter, arseniuretted hydrogen (*hydrogen arsenide*) is evolved. It is, however, only the arsenous acid that will respond to this test, so that if the arsenic be present as arsenic acid it must first be reduced to the arsenous condition by some reducing agent like sulphurous oxide or hydrogen sulphide. For an account of the process, and of the method of rendering arsenic acid sensible to the test, and of counteracting the influence of antimony and mercury, see papers by Mr. C. L. Bloxam in *P. J. Tr.* (1860, p. 376, and 1861, p. 528).

It has been shown by MM. Malaguti and Sarzeau that for the detection of minute quantities of arsenic in exhumed bodies the best method of proceeding is to distil the viscera with aqua regia, made by mixing one part of nitric with three of hydrochloric acid. The animal matter (the liver, for example), cut into small pieces, is dried by a gentle heat, and mixed with a quantity of the aqua regia equal to the weight of the matter before it was dried. The mixture is

distilled, and the arsenic, if present, comes over in the form of the volatile terchloride, which may be converted into the tersulphide in the usual manner.

Arsenic may be detected in exhumed bodies long after death. M. Blondlot found it in the brain of a body that had been buried twenty years. In this case it was ascertained that no arsenic existed in the earth of the cemetery. (See *Brit. and For. Med.-Chir. Rev.*, 1855, p. 222.) It is necessary also to be guarded against the possible presence, about the body, of metals which may contain arsenic; as, for example, brass and copper. L. A. Buchner has found, in the intestines of persons who had been poisoned with arsenous acid, examined some months after death, the poison in the state of yellow arsenic sulphide, into which it had been converted by the hydrogen sulphide developed by the putrefactive process that had taken place in the bowels, showing that even in poisonous doses arsenic has not always the property of preserving the body from corruption. (*Neues Repertorium*, xvii. 21.)

ACIDUM BENZOICUM. U.S., Br. Benzoic Acid.

$HC_7H_5O_2$; 121·71. (ĂÇ'Ĭ-DŬM BĔN-ZŌ'Ĭ-ÇŬM.) $HC_7H_5O_2$; 122.

"An organic acid, usually obtained from benzoin by sublimation, or prepared artificially, chiefly from toluol. It should be kept in dark amber-colored, well-stoppered bottles, in a cool place." *U. S.* "Benzoic Acid, $C_6H_5.COOH$, is obtained from benzoin by sublimation. It may also be obtained from toluene, from hippuric acid, and from other organic compounds." *Br.*

Acidum Benzoicum Sublimatum, Flores Benzoes (Flowers of Benzoin); Acide benzoïque, Fleurs de Benjoin, *Fr.*; Benzoesäure, Benzoeblumen, *G.*

Both the U. S.* and Br. Pharmacopœias have omitted processes for the preparation of benzoic acid: the British defines it to be an "acid obtained from benzoin, and prepared by sublimation, not chemically pure."

Formerly the benzoin before sublimation was mixed with sand; but this is now usually omitted, as not only useless, but probably injurious by favoring the production of empyreumatic substances. The acid, which exists in the benzoin combined with resin, is volatilized by the heat, and condensed in the upper part of the apparatus. Unless the temperature be very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid, and gives it a brown color, from which it cannot be entirely freed by bibulous paper; and this result, even with the greatest caution, sometimes takes place. The process for subliming benzoic acid may be conducted in a glazed earthen vessel, surmounted by a cone of paper, or by another vessel with a small opening at the top, and a band of paper pasted round the place of junction. After the heat has been applied for an hour, the process should be suspended till the condensed acid is removed from the upper vessel or paper cone, when it may be renewed, and the acid again removed, and thus alternately till colored vapors rise. Mohr, after many experiments, recommends the following plan as unobjectionable. In a round cast-iron vessel, eight or nine inches in diameter and two inches deep, a pound or less of coarsely powdered benzoin is placed, and uniformly strewed over the bottom. The top of the vessel is closed by a sheet of bibulous paper, which is secured to the sides by paste. A cylinder of thick paper in the form of a hat, just large enough to fit closely around the sides of the pot, is then placed over it, and in like manner secured by paste. A moderate heat is now applied by means of a sand-bath, and continued for three or four hours. The vapors pass through the bibulous paper, which absorbs the empyreumatic oil, and are condensed within the hat in brilliant white flowers, having an agreeable odor of benzoin. (*Annal. der Pharm.*, xxix. 178.) The process official in U. S. P. 1870 was based upon Mohr's, but it frequently happens that the sublimed crystals, after they have formed in the cap, and whilst the sublimation is still going on, fall upon the bibulous paper, and if this paper should happen to be heated to only 120° C. (248° F.) the crystals will melt, and soon stop up the pores of the paper. If coarse muslin be substituted for the bibulous paper, it serves the purpose of retaining any empyreumatic substances, and yet permitting the vapors to pass through without becoming glazed by a deposit of melted acid. Strips of paper passed at irregular intervals across the cap prevent the falling back of crystals. The remaining acid of the benzoin may be extracted, if deemed

* The following is the process official in 1870: "Take of Benzoin, in coarse powder, *twelve troyounces*. Spread the Benzoin evenly over the bottom of an iron dish eight inches in diameter; cover the dish with a piece of filtering paper, and, by means of paste, attach it closely to the rim. Then, having prepared a conical receiver or cap of thick, well-sized paper, of rather larger diameter than the dish, invert it over the latter, so as to fit closely around the rim. Next apply heat by means of a sand-bath, or of the iron plate of a stove, until, without much empyreuma, vapors of Benzoic Acid cease to rise. Lastly, separate the receiver from time to time, and remove the Benzoic Acid from it and the paper diaphragm, as long as the Acid continues to be deposited." *U. S.* 1870.

advisable, by treating the residue of the balsam with lime or sodium carbonate. From the mode of preparing benzoic acid by sublimation, it was formerly called *flowers of benzoin.*

Another mode of separating the acid from benzoin is by combining it with a salifiable base and precipitating with an acid. Such is the process of Scheele. It consists in boiling the powdered benzoin with lime hydrate and water, filtering the solution of calcium benzoate thus obtained, and precipitating the benzoic acid with hydrochloric acid. In order to get the benzoic acid in the ordinary form, it has been proposed to sublime the acid after its precipitation.

Several other modes of extracting the acid have been recommended. The following is the process of Stolze. One part of the benzoin is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by sodium carbonate dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off; and the sodium benzoate contained in the residuary liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which lets fall the acid when it cools. By this process Stolze obtained 18 per cent. of acid from benzoin containing 19·425 per cent. By the process of Scheele he obtained 13·5 per cent.; by the agency of sodium carbonate, 12 per cent.; by sublimation, only 7·6 per cent. Professor Scharling has prepared benzoic acid by means of heated steam, and obtained 8 per cent. (*A. J. P.*, xxiv. 236.)

The acid is manufactured very cheaply by synthetic methods. The two most commonly employed are those which start either with *toluene*, $C_6H_5CH_3$, or *naphtalin*, $C_{10}H_8$. In the first method the toluene is changed to benzotrichloride, $C_6H_5.CCl_3$, and this heated with water to 150° C. (302° F.) in closed vessels generates benzoic acid. By the second method naphtalin is changed first into naphtalin tetrachloride, and this by the action of nitric acid into phthalic acid, $C_6H_4(COOH)_2$. This is converted into a calcium phthalate and strongly heated with lime hydrate, whereby the phthalate is converted into calcium carbonate and benzoate; this latter salt is then treated with hydrochloric acid, and the benzoic acid thus set free. This acid is frequently resublimed in contact with benzoin, in order to give it the vanilla-like odor of the acid sublimed from the gum. A method of making benzoic acid from tannin or gallic acid is described in *Pharm. Era*, 1892, 172 P. Schulze produced benzoic acid by heating benzal chloride or benzotrichloride in the presence of ferric benzoate or metallic iron. The process is patented. (*Pharm. Centralh.*, 1896, 221.)

Under the name of *German benzoic acid*, there has been largely imported into the United States benzoic acid prepared from the urine of cattle and horses by boiling the calcium hippurate with hydrochloric acid. By boiling the hippuric acid thus separated with hydrochloric acid, it is split into benzoic acid and glycocoll,* according to the reaction $C_9H_9NO_3 + H_2O = C_2H_5NO_2 + C_7H_6O_2$. It is white, has a fine lustre, and is said to be very pure, but sometimes has a slight urinous odor indicative of its origin. (*A. J. P.*, xxvii. 23; *P. J. Tr.*, July, 1875.) Owing to the scarcity in the market of benzoin yielding paying quantities of benzoic acid, it is asserted that the English manufacturers employ certain varieties of Botany Bay gum (*Gum acroides*), and obtain a larger yield of an acid which was at one time regarded as cinnamic, but has been shown to be benzoic acid. (*N. R.*, Feb. 1879.)

Properties. Sublimed benzoic acid is in "white, or yellowish-white, lustrous scales or friable needles, odorless, or having a slight, characteristic odor resembling that of benzoin, and of a warm, acid taste; somewhat volatile at a moderately warm temperature, and rendered darker by exposure to light." From solution the acid crystallizes in transparent prisms. When quite pure it is inodorous; but prepared by sublimation from the balsam it has a peculiar, agreeable, aromatic odor, dependent on the presence of an oil, which may be separated by dissolving the acid in alcohol and precipitating it with water. Its taste is warm, acrid, and acidulous. It is unalterable in the air, but at 121·5° C. (250° F.) melts, and at a somewhat higher temperature rises in suffocating vapors. Sp. gr. 1·29. The Br. Pharmacopœia gives as its melting point 121·4° C. (250·5° F.); "but when obtained from benzoin, it melts at about 248° F. (120° C.), forming a yellowish liquid which becomes brownish but not red as the temperature rises (absence of hippuric acid), and boils at about 462° F. (238·9° C.). When heated to the last-named temperature, it passes off in vapor which burns with a bright-yellow flame, and leaves only a slight residue." *Br.* It is inflammable, burning without residue. One hundred parts of 90 per cent. alcohol dissolve about forty parts, whilst the same quantity of pure ether will dissolve about thirty parts. (*Bourgoin.*) The addition of borax or sodium

* Cazeneuve recommends the precipitation of the acid from urine by the use of zinc sulphate, as zinc hippurate, decomposing with hydrochloric acid. (*Zeitschr. Oest. Ap. Ver.*, 1879, p. 2.)

phosphate increases its solubility. It is readily dissolved by alcohol, and by concentrated sulphuric and nitric acids, from which it is precipitated by water. "Soluble, when pure, in about 500 parts of water, and in 2 parts of alcohol at 15° C. (59° F.); in 15 parts of boiling water, and in 1 part of boiling alcohol. Also soluble in 3 parts of ether, 7 parts of chloroform, and readily soluble in carbon disulphide, benzol, fixed and volatile oils, but sparingly soluble in benzin." *U. S.* "It is soluble in 400 parts of cold or 17 parts of boiling *water*, in its own weight of *absolute alcohol*, in 3 parts of *alcohol* (90 per cent.), in 2·5 of *ether*, in 7 of *chloroform*, and in the fixed and volatile oils; also in solutions of the alkalies and of *calcium hydroxide*, forming benzoates, and it is precipitated from these on the addition of *hydrochloric acid* unless the solutions are very dilute." *Br.* It is entirely soluble in solutions of potassa, soda, or ammonia, from which it is precipitated by hydrochloric acid. On carefully neutralizing any of these solutions and adding solution of ferric sulphate previously diluted with water, a flesh-colored precipitate is produced. Its solution reddens litmus paper, and it forms salts with salifiable bases called benzoates.

"Benzoic Acid volatilizes freely with the vapor of water. On heating it to 100° C. (212° F.), it begins to sublime. At 121·4° C. (250·5° F.) it melts, and at a higher temperature it is consumed without leaving a residue. The acid sublimed from benzoin has a lower melting point, and a greater solubility in water. Benzoic Acid has an acid reaction. On heating Benzoic Acid gradually, with 3 parts of freshly slaked lime, in a retort, benzol is evolved. The Acid is freely soluble in solutions of alkali hydrates. On carefully neutralizing such a solution, and adding ferric chloride test-solution, previously diluted with 2 volumes of water, and neutralized, if necessary, by ammonia, a flesh-colored precipitate of ferric benzoate is produced. A solution of Benzoic Acid in pure, cold sulphuric acid, when gently warmed, should not turn darker than light brown; if it is then poured into water, the Benzoic Acid should separate as a white precipitate, and the liquid should be colorless (absence of *readily carbonizable, organic matters*). If 0·5 Gm. of the Acid and 0·8 Gm. of calcium carbonate be mixed with a little water in a crucible, the mixture dried, gently ignited, and then dissolved in water, with the aid of nitric acid in slight excess, so as to obtain 20 C.c. of filtrate, the addition of silver nitrate test-solution to the latter should not produce much more opalescence (if at all) than is produced by the same reagent in a solution measuring 20 C.c. prepared by dissolving 0·8 Gm. of the same calcium carbonate in water with the aid of nitric acid (absence of more than traces of *chlorine*). On warming 0·5 Gm. of the Acid with 5 C.c. of water and 0·5 Gm. of potassium permanganate in a test-tube loosely stoppered and placed in a water-bath heated to about 45° C. (113° F.), then tightly stoppering, and cooling the test-tube with cold water, upon removing the stopper, no odor of oil of bitter almond should be discernible (absence of *cinnamic acid*)." *U. S.* "When 0·5 gramme is heated in a closed crucible with twice its weight of *calcium carbonate*, the mass dissolved in *diluted nitric acid*, and *solution of silver nitrate* added, only the slightest cloudiness should result (absence of chlorobenzoic acid). It should yield no characteristic reaction with the tests for oxalates. It should not develop the odor of benzaldehyde when warmed with its own weight of *potassium permanganate* and ten times its weight of *diluted sulphuric acid* (absence of cinnamic acid). 0·2 gramme suspended in 10 cubic centimetres of *water* should not immediately discharge the color of two drops of *solution of potassium permanganate* (absence of hippuric and cinnamic acids)." *Br.*

Benzoic acid is a characteristic constituent of the balsams, and has been found in various other vegetable and some animal products. When heated, it should sublime without residue; but the Br. Pharmacopœia allows a slight residue for impurities.

Potassium permanganate has been depended upon more than any other reagent to distinguish between benzoic acids as obtained from different sources. Schacht proposes the following modification of the German Pharmacopœia test: if 3 grains of benzoic acid be dissolved in 96 minims of solution of potassa, sp. gr. 1·777, diluted with 96 minims of distilled water, and 10 drops of a solution made by dissolving 1 grain of potassium permanganate in 200 grains of water be added to it and the whole heated to boiling, dark green liquids (in which brown precipitates gradually appear) are produced if the benzoic acid be obtained from urine, from toluol, or from commercial benzoin, whilst if the benzoic acid be from Siam benzoin (sublimed or made by wet process) decoloration of the liquids and brown precipitates are produced, due to the presence of cinnamic acid. (*Pharm. Centralhalle*, 1881, 565.) The odor of bitter almonds confirms the presence of cinnamic acid. It is claimed that benzoic acid from benzoin can be distinguished from that from other sources by adding resorcin and sulphuric acid to the alcoholic solution of the acid. The benzoic acid gives a beautiful red color,

due probably to a trace of vanillin or other aldehyde in the natural product. (Göldner, *Pharm. Zeit.*, 1892, p. 697.)

Medical Propertie and Uses. Benzoic acid is irritant to the alimentary mucous membrane, and as a stimulant expectorant is of some value in *chronic bronchitis* and the later stages of the acute disorder. Led by his belief that it has the power of converting uric acid into hippuric acid, Dr. Alexander Ure many years ago proposed benzoic acid as a remedy for the dissolving of deposits of the urates, but it is now proved that the hippuric acid which appears in the urine of those taking benzoic acid is formed out of the benzoic acid itself. This conversion would appear to take place in the kidneys, since, after the exhibition of large doses, benzoic and not hippuric acid can be detected in the blood; whilst even small amounts of hippuric acid injected into the blood produce violent poisoning. Moreover, Bunge and Schmiedeberg have succeeded in converting benzoic acid into hippuric acid by passing blood containing benzoic acid slowly through kidneys immediately after their removal from the body. In rare cases, according to Meissner and Shepard, the benzoic acid is converted into succinic instead of hippuric acid. When it is given very freely a portion of the benzoic acid escapes unchanged. Where the nitrogen necessary for the conversion of the benzoic into hippuric acid comes from is at present unknown. *A priori* it would seem probable that the source of this nitrogen was the urea, but the testimony as to the effect of the injection of benzoic acid upon the urea and uric acid of the urine is entirely contradictory. Investigators are about equally divided in their findings that the uric acid is very much diminished, and that it remains normal; a fact which is also true of urea. In our own experience benzoic acid has seemed to be a very useful remedy in *uric acid gravel*, though without specific influence on the uric acid diathesis.

The urine is always strongly acidified by the free administration of benzoic acid, so that the remedy is useful in *phosphatic gravel* and in *ammoniacal cystitis* with a tendency to a deposit of the phosphates. Its beneficial influence, of course, continues only during its administration, and it is necessary to give it in very large doses—up to a drachm a day. It has been strongly recommended in *nocturnal incontinence*, and has also sometimes been given with advantage in various forms of *cystitis* and even in acute *gonorrhœa*. As first pointed out by Dougall in 1872, benzoic acid is a powerful antiseptic. Bucholz found that 0·2 per cent. of it has a decided influence upon the development of the organisms of putrefaction; and F. Baden Benger (*P. J. Tr.*, 1875, p. 211) states that one-fourth of a grain of it added to a fluidounce of infusion of orange, buchu, or gentian will cause the infusion to keep unchanged for at least one month.

Benzoic acid may be readily dissolved in water by the addition to it of four parts of sodium phosphate, or one part and a half of sodium biborate. The dose is from 10 to 30 grains (0·648–1·9 Gm.). It may be administered in pill, using soap as an excipient. It is an ingredient in some cosmetic washes, and has been employed by way of fumigation as a remedy in affections of the skin. It has also been employed as a local hæmostatic, in connection with alum, with considerable asserted success; but there can be little doubt that alum is the more efficient ingredient.

ACIDUM BORICUM. U.S., Br. Boric Acid. [Boracic Acid.]

H_3BO_3; 61·78. (ĂS'Ĭ-DŬM BŌ'RĬ-CŬM.) H_3BO_3; 62.

Acidum Boracicum; Boracic Acid; Hydrogen Borate; Acide borique, *Fr.*; Borsäure, *G.*

"A weak acid having the formula H_3BO_3. Obtained by the interaction of sulphuric acid and borax, and by the purification of native boric acid." *Br.*

Boric acid occurs in small amount, most probably in combination as a magnesium salt, in sea-water and in certain mineral waters, as the hot springs of Wiesbaden, Aix-la-Chapelle, and Vichy; in certain mineral substances, such as the *borocalcite* which occurs in considerable quantities in the nitre-beds of Chili; in the natural borax or *tincal*, first found in the basins of dried-up lagoons in Central Asia, and afterwards in large amount in Clear Lake, California; in *ulexite* (sodium and calcium borate) and *colemanite* (calcium borate). The last of these minerals now yields by far the largest amount of the boric acid obtained on the Pacific coast. It is found in a large vein deposit in San Bernardino County, California, where it is mined and shipped to the works of the Pacific Coast Borax Company at Alameda, California. Boric acid itself is extracted, under the name of *sassolin*, from the lagoons of the volcanic districts of Tuscany, and from the crater of Vulcano, one of the Lipari Islands.

Preparation. In the neighborhood of Monte Rotondo, Lago Zolforeo, Sasso, and Larderello are found numerous hillocks and fissures, the latter of which emit hot aqueous vapor containing boric acid and certain gases. Around one or several of these fissures, called *suffioni*, a circular basin of masonry is built, which is filled with water and called a lagoon. By the jets of vapor constantly breaking through it, the water becomes gradually impregnated with boric acid and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is allowed to rest and deposit mechanical impurities. From this reservoir the solution is made to pass into leaden evaporating pans, heated by the natural vapor, where it receives sufficient concentration to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid thus obtained contains from 74 to 84 per cent. of boric acid; the impurities consisting chiefly of alum, the double ammonium and magnesium sulphate, and calcium sulphate. The production of Tuscan boric acid for the year 1887 was stated to be 3500 tons, in addition to 500 tons of borax made direct at the works, while that for 1891 was 3831 metric tons.

The native borax minerals of California supply, at present, the entire American demand for boric acid. The American production of refined borax, including boric acid, was 13,506,356 pounds in 1895, 15,258,014 pounds in 1896, and 21,422,300 pounds in 1897. The free acid is obtained by decomposing the salt in aqueous solution with strong hydrochloric acid.

Properties. Boric acid forms "Transparent, colorless scales, of a somewhat pearly lustre, or, when in perfect crystals, six-sided, triclinic plates, slightly unctuous to the touch, odorless, having a faintly bitterish taste, and permanent in the air. Soluble, at 15° C. (59° F.), in 25·6 parts of water, and in 15 parts of alcohol; also soluble in 10 parts of glycerin. Addition of hydrochloric acid increases its solubility in water." *U. S.* "Soluble in 30 parts of cold *water*, in 4 of *glycerin*, in 30 of *alcohol* (90 per cent.), and in 3 of boiling *water*." *Br.* Boric acid has a sp. gr. of 1·434, dissolves in three parts of boiling water and in volatile oils, but is insoluble in ether. On evaporation of the alcoholic solution, the boric acid volatilizes even more readily than from the aqueous solution. Glycerin, when heated, dissolves a very large quantity of boric acid. (See *Glyceritum Boroglycerini;* also *Boroglyceride*, PART II.*) Its aqueous solution tastes somewhat acid, colors litmus paper a wine red, and changes turmeric paper to a brown color, analogous to that produced by alkalies, even when hydrochloric acid is present. On moistening the paper so browned and then dried with caustic alkali solution, it turns first blue and then a dirty gray color. "When heated to 100° C. (212° F.), Boric Acid loses water, forming metaboric acid (HBO_2), which slowly volatilizes at that temperature. Heated to 160° C. (320° F.), it fuses to a glassy mass of tetraboric (or pyroboric) acid ($H_2B_4O_7$); at a higher temperature the fused mass swells up, loses all of its water, and becomes boron trioxide (B_2O_3), which fuses into a transparent, non-volatile mass. From a boiling solution, Boric Acid readily volatilizes. The solution in alcohol or glycerin burns with a flame enveloped with a green-colored mantle. An aqueous solution (1 in 50) of Boric Acid colors blue litmus paper red, but yellow turmeric paper brownish-red after drying, even when the solution had been acidulated with hydrochloric acid; this brownish-red color is changed to bluish-black by ammonia water." *U. S.* "It changes the color of *litmus* to wine-red in the cold, a hot saturated solution giving a bright red color; *turmeric paper* moistened with an aqueous solution, even when slightly acidulated with *hydrochloric acid*, becomes brownish-red on gently drying, and this color changes to a greenish-black if *solution of potassium hydroxide* be added. The solution in *alcohol* burns with a flame tinged with green, especially when the solution is acidulated with *sulphuric acid*. Boric Acid liquefies when warmed, and on careful heating loses 43·6 per cent. of its weight, the product solidifying, on cooling, to a brittle glass-like mass. It should yield no characteristic reaction with the tests for lead or copper, and only the slightest reactions with the tests for iron, calcium, magnesium, potassium, sodium, ammonium, chlorides, and sulphates." *Br.*

Boric acid is a weak acid, or may even act as a base. Thus, with sulphuric and phosphoric acids it forms compounds which may be considered as salts. Its compounds with bases, when in solution, are readily decomposed by other acids, but at red heat boric oxide will displace many of the stronger but more volatile acids. "A 2-per-cent. aqueous solution of the Acid should not be precipitated by barium chloride test-solution (absence of *sulphate*); silver nitrate test-solution with nitric acid (absence of *chloride*); ammonium sulphide test-solution (*lead, copper, iron*, etc.); ammonium oxalate test-solution (*calcium*); or sodium phosphate test-solution

* *Antibacteride.* For an account of this substance see U. S. D., 16th ed.

and ammonia water (*magnesium*). No odor of *ammonia* should be evolved by heating the Acid with potassium or sodium hydrate test-solution. In a solution of 1 Gm. of Boric Acid in a mixture of 1 C.c. of hydrochloric acid and 49 C.c. of water, 0·5 C.c. of potassium ferrocyanide test-solution should not at once produce a blue color (limit of *iron*). A fragment heated on a platinum wire (thoroughly cleansed by washing and heating, until it no longer colors the flame) should not impart to the non-luminous flame a persistent yellow color (absence of *sodium*)." *U. S.* M. Schäuffele, of Paris, has drawn attention to a commercial boric acid containing lead. (*N. R.*, July, 1877.)

Boric acid requires thirty parts of water to dissolve it, and this fact has led to many attempts to increase its solubility without interfering with its usefulness. The use of glycerin has been officially sanctioned. Scholz and Mansier recommend the use of magnesium carbonate (11 per cent.), but such an addition is not always permissible. When equal parts of boric acid and borax are dissolved in boiling water a crystalline mass separates on cooling, which has been termed *boro-borax*. Its advantages are increased solubility and neutral reaction. The remarkable volatility of boric acid when in alcoholic solution has been observed by Dr. Schneider and the fact utilized in its quantitative determination. (*Zeitschr. Oest. Apoth. Ver.*, 1896, 791.)

Medical Properties and Uses. The physiological action of boric acid and its salts is a very feeble one, yet severe and even fatal cases of poisoning from it have been reported. The symptoms have been great depression of spirits, fall of bodily temperature, a pulse which is either rapid or slow but always very feeble, nausea, violent vomiting, hiccough, sometimes an erythematous eruption accompanied with much œdematous swelling, ecchymoses, disturbance of respiration, and, very late in the poisoning, coma followed by death. The acid escapes rapidly from the system, and to some extent through all the secretions, but especially by the urine. It has been demonstrated by E. T. Stewart and H. C. Wood to act as a depressant upon the spinal centres, and also to have a depressant influence upon the heart itself.

Boric acid and its salts are usually poisonous to the lower forms of life, and have considerable antiseptic power, but the experiments of Sternberg and of Andrews have shown that this influence is too feeble to be depended upon against pathogenetic germs. The acid acts upon mucous membranes as a soothing detergent, is nearly free from irritating properties, and is much used as a local application in mucous membrane inflammations, such as *conjunctivitis*, *aphthous ulceration of the mouth*, and even *diphtheria*.

In antiseptic surgery the remedy has been tried, but has failed to take rank with more powerful agents. A lint made by saturating ordinary patent lint, or an ointment produced by melting one part each of spermaceti and white wax with six parts of vaseline and adding while hot two to four parts of a saturated glycerite of boric acid, may be used. In treating wounds, it is often desirable to use a solution containing more than 4 per cent. of boric acid (the extent of its solubility in water). Jaenicke proposes for this purpose a mixture of equal parts of boric acid and borax, of which 16 per cent. is soluble in water at ordinary temperature. It is said to be non-irritating, non-poisonous, and efficacious: being soluble to the extent of 30 per cent. in water at the temperature of the blood, the solution can be applied to the interior of organs, and on cooling the crystals of the compound separate. (*A. J. P.*, 1892, 97.) In *ammoniacal cystitis* boric acid may be given internally, and the washing out of the bladder with a saturated solution of the acid or of borax often acts most happily. Dose of the acid, ten grains (0·647 Gm.) three to six times a day; strength of the solution for use on the conjunctiva or other mucous membrane, from five grains to the ounce up to saturation.

Fatal cases of boric acid poisoning have been produced by the immoderate use of its solution in washing out internal cavities. Two ounces of boric acid in the vagina produced violent poisoning, but were recovered from.

The tendency of the crystals of boric acid to slip from under the pestle renders the process of pulverization very tedious. It is essential that the acid be in an impalpable powder when it is desired to make an ointment. The gradual addition of ether to the acid has been suggested as a valuable aid to trituration. Boric acid ointment (Lister's) is made from one part each of boric acid and white wax, and two parts each of oil of sweet almonds and paraffin.

ACIDUM CARBOLICUM. U. S., Br. Carbolic Acid. (Phenol.)

C_6H_5OH; 93·78. (ĂC'Ĭ-DŬM CĂR-BŎL'Ĭ-CŬM.) C_6H_5HO; 94.

"A constituent of coal-tar, obtained by fractional distillation, and subsequently purified. Carbolic Acid should be kept in dark amber-colored, well-stoppered vials." *U. S.* "Phenol,

C_6H_5OH, commonly termed carbolic acid, is obtained from coal-tar oil by fractional distillation." *Br.*

Acidum Phenicum s. Phenylicum Crystallisatum; Phenic Acid; Phenylic Acid; Phenol; Phenylic Alcohol; Acide carbolique, Hydrate de Phényle, Acide phénique, *Fr.*; Carbolsäure, Phenylsäure, Phenylalkohol, *G.*

This important medicine was discovered in 1834, in the tar of coal, by Runge, who gave it the name of carbolic acid. When on the subject of its composition, we shall have occasion to show that, although more closely related chemically with the alcohols than the acids, it belongs to a peculiar class known in common as *phenols*. The British Pharmacopœia no longer officially recognizes the name of carbolic acid, but uses "phenol" as the English name for this substance.

Preparation. For the commercial preparation of carbolic acid the light oil fraction is collected until a sample of the oil that runs from the still sinks in water. This fraction, with a sp. gr. of from 0·94 to 0·99, boils between 90° and 250° C. and contains from 4 to 10 per cent. of acids, and therefore nearly all the carbolic acid or true phenol which boils at 182° C. The oil from which the phenol is to be extracted is agitated with a weak solution of caustic soda, 10 per cent. strength being strong enough. If a stronger solution is used many impurities, like naphtalene, are dissolved and contaminate the finished acid. After agitation, the mixture, on standing, separates into two layers, the upper consisting of the extracted oil and the lower the solution of sodium carbolate. To this solution, after separation from the oily layer, an amount of hydrochloric or dilute sulphuric acid calculated from a special test with a small portion, as just sufficient, is then added in order to set the carbolic acid free. It separates as an oily layer upon the surface, and, after being washed with a saturated solution of common salt, is dried over calcium chloride and again distilled. The product thus obtained crystallizes out largely on a cooled surface, and, after removing the crystals from adhering liquid, and drying them by pressure, they are again submitted to the same process of distillation. Only by such a detailed procedure can carbolic acid be separated from its homologues, like cresol (cresylic acid), $C_6H_4(CH_3)OH$, which accompany it, smell exactly like it, and boil between 185° C. (365° F.) and 200° C. (392° F.).

Prof. Church (*Chem. News*, Oct. 13, 1871) proposes to prepare *pure* carbolic acid by agitating the best commercial product with 20 parts of water, siphoning off the clear solution from the undissolved portion which retains the impurities, and adding to the solution pure common salt to saturation, when the purified acid rises to the top, and may afterwards be dehydrated by distillation with lime.

Within recent years German manufacturers have put upon the market "*synthetical carbolic acid*," for which is claimed a greater purity than that extracted from coal-tar. It may be made synthetically in one of two ways,—either from benzene, which is converted into *benzene-sulphonic acid*, the sodium salt of which is then fused with an excess of caustic soda, producing sodium carbolate and sodium sulphite, from which, on the addition of sulphuric or hydrochloric acid, the phenol separates and may be distilled off; or a pure aniline oil is taken, neutralized with sulphuric acid, and to the acid solution sodium nitrite is added. The nitrous acid liberated forms at first *diazobenzene sulphate;* but this at once decomposes into phenol, sulphuric acid, and nitrogen, the reactions being as follows:

$$(C_6H_5NH_2)_2H_2SO_4 + 2HNO_2 = (C_6H_5N{=}N)_2SO_4 + 4H_2O;$$
$$(C_6H_5N{=}N)_2SO_4 + 2H_2O = 2C_6H_5OH + H_2SO_4 + 4N.$$

The synthetic acid melts at 41°–42° C., and boils at 178° C. (352·4° F.). It is as yet considerably dearer than the coal-tar carbolic acid.

Commercial Forms. In one of his publications in reference to carbolic acid, Dr. F. Crace Calvert, to whom probably more than to any other person is owing the introduction of this substance into use in Great Britain and the United States, informed us that the carbolic acid obtained by Laurent, melting at 34° C. (93° F.), and boiling at 186° C. (367° F.), was not quite pure. By successive steps of improvement in the process employed by the manufacturing house at Manchester with which he is connected, they had at length succeeded in preparing the pure crystallized acid, without color or sulphurous odor; but, unfortunately, this statement is not accompanied with an account of the means by which the end had been attained. As the products of this factory are those now generally used, a brief notice, derived from the same source, of the forms of the drug prepared by them, and now circulating in the market, is desirable. 1. A pure acid is prepared, crystallizing in white prismatic crystals, but, as usually sold, in a white, hard, fused mass, which differs from Laurent's in being soluble in 20 parts of water instead of 33 parts, fusible at 41° C. (106° F.) instead of 34° C. (93° F.), and boiling at 182° C. (359° F.) instead of 186° C. (367° F.). This should be preferred for internal

use. 2. The second form is less pure. Like Laurent's, it is white, solid, and fusible at 34° C. (93° F.), and may be employed for external purposes, whether in medicine or surgery. 3. A third quality is known in commerce as solution No. 4, which is not crystallizable at ordinary temperatures, and contains at least 10 per cent. of water, with varying quantities of homologous acids. 4. The fourth and cheapest form is that of a nearly colorless liquid, which is a mixture of carbolic and cresylic acids. Diluted with 100 parts of water or more, it may be used for the coarser antiseptic and disinfecting purposes out of doors, as in cess-pools and sewers. Besides these forms of carbolic acid, which issue from the manufacturing establishment of the Messrs. Calvert, there are others from different sources, generally in the liquid state, which are usually of a brownish color, and consist of mixtures of carbolic acid with cresylic acid, coloring matter, etc., and of which carbolic acid often constitutes but a small proportion. These are often imported from Germany. They should not be used internally; but for disinfectant and antiseptic purposes they are probably equal to solutions of the pure acid, as the cresylic acid is said to be quite as powerfully disinfectant as the carbolic, if not more so.

These impure liquors are sold sometimes under the improper name of *coal-tar creosote*. They are recognized in the U. S. Pharmacopœia under the name of "Acidum Carbolicum Crudum."

Properties. Carbolic acid, in its pure state, is a solid at ordinary temperatures, crystallizing in minute plates or long rhomboidal needles, white or colorless, of a peculiar odor recalling that of creosote, and an acrid burning taste. Its sp. gr. is 1·065. (*Lemaire.*) It is apt to be colored pinkish or brown under the influence of light and air. This reddening has been ascribed to various causes, such as ammonia and ammonium nitrite in the air, rust-spots in tinned iron vessels, alkali in glass vessels, organic matter, etc. It is said to be due to oxidation; stannous chloride solution acquires a green color when shaken with the red-colored acid. Demant recommends the removal of the red color by adding to 89 parts of the melted acid 11 parts of alcohol, subjecting the mixture to freezing, and then draining off the portion remaining liquid. Perfectly white crystals can be thus obtained. A slight discoloration does not interfere with any of the medical uses of the acid. Carbolic acid deliquesces on exposure, and becomes liquid; and the presence of water in the smallest proportion causes it to liquefy. It is customary to add 10 per cent. of water or glycerin to carbolic acid for dispensing, as it is more convenient to use in a liquid form. (See p. 41.) When diluted it has a sweetish taste with a slightly burning after-taste, and a faintly acid reaction. When quite pure it melts at 41° C. (106° F.), forming an oily looking, colorless liquid, and boils at 182° C. (359° F.). (*Calvert.*) But, as often met with, its point of fusion is lower, and that of volatilization higher, than those named. "When gently heated, Carbolic Acid melts, forming a highly refractive liquid. It is also liquefied by the addition of about 8 per cent. of water. If the Acid be liquefied by a gentle heat, and then slowly cooled, under constant stirring, until it is partly recrystallized, the semi-liquid mass should show a temperature (remaining stationary for a short time) not lower than 35° C. (95° F.). The Acid should have a boiling point not higher than 188° C. (370·4° F.). A lower boiling point, or a higher melting point, indicates a purer or less hydrated acid. When heated upon a water-bath, the Acid should be volatilized without leaving a residue. The vapor of the Acid is inflammable." *U. S.* The Br. Ph. gives its melting point at not lower than 102° F. (38·8° C.), and its boiling point not higher than 359.6° F. (182° C.). Specific gravity at the melting point from 1·060 to 1·066. It is "soluble, at 15° C. (59° F.), in about 15 parts of water, the solubility varying according to the degree of hydration of the acid. Very soluble in alcohol, ether, chloroform, benzol, carbon disulphide, glycerin, fixed and volatile oils. Almost insoluble in benzin." *U. S.* "Freely soluble in *alcohol* (90 per cent.), *ether*, *benzol*, *chloroform*, *carbon bisulphide*, *glycerin*, in the fixed and volatile oils, and in solutions of alkalies. Exposed to moist air it may acquire a pinkish tinge. At 60° F. (15·5° C.), 100 parts of Phenol should be liquefied by the addition of 10 parts of *water*, should form a clear liquid with 30 to 40 of *water*, and should be completely dissolved by 1200 of *water*. The aqueous solution should be clear and colorless." *Br.* Its solubility in water increases on heating the water; at 84° C. (183·2° F.) both liquids are miscible in all proportions. Its solution is, if pure, colorless, and remains so; but, if impure, is colored brownish by exposure. It is but slightly soluble in cold petroleum benzin, but dissolves largely on heating. *Sodium sulphoricinate* has been used to increase the solubility of phenol, the advantage being that it will retain 40 per cent. of phenol in solution without destroying its antiseptic power, making a solution without causticity.

"The aqueous solution of the Acid yields, with bromine water, a white precipitate which at

first redissolves, but becomes permanent as more of the reagent is added, and appears crystalline when viewed under the microscope. On adding to 10 C.c. of a 1-per-cent. aqueous solution of the Acid, 1 drop of ferric chloride test-solution, the liquid acquires a violet-blue color which is permanent; and on adding Carbolic Acid either to albumen or to collodion, coagulation takes place (difference from *creosote*). One volume of cold, liquefied Carbolic Acid (rendered liquid by the addition of 8 per cent. of water) forms, with 1 volume of glycerin, a clear liquid which is not rendered turbid by the addition of 3 volumes of water (absence of *creosote* or of *cresylic acid*). If 0·039 Gm. of Carbolic Acid be tested by the method immediately following, there should be required for its complete conversion into tribromophenol not less than 24 C.c. of bromine decinormal volumetric solution (each C.c. of the volumetric solution corresponding to 4 per cent. of absolute Phenol)." *U. S.* "Phenol does not immediately redden *blue litmus* paper. It does not rotate the plane of a ray of polarized light. It coagulates *solution of albumen* and *collodion*, and liquefies Camphor. *Test-solution of ferric chloride* strikes a deep purple color, and excess of *solution of bromine* gives a white precipitate, with a cold aqueous solution of Phenol. An aqueous solution of Phenol mixed with one-fourth of its volume of *solution of ammonia*, and then with a few drops of *solution of chlorinated soda*, becomes blue after a time or immediately on gently heating. One volume of Phenol, liquefied by the addition of 10 per cent. of *water*, forms with 1 volume of *glycerin* a clear liquid which is not rendered turbid by the addition of 3 volumes of *water* (absence of cresol)." *Br.*

The U. S. Pharmacopœia of 1890 gives a method of valuing carbolic acid as follows:

"**Valuation of Carbolic Acid.** Dissolve 1·563 Gm. of the Carbolic Acid to be valued, in a sufficient quantity of water to make 1000 C.c. Transfer 25 C.c. of this solution (containing 0·039 Gm. of the acid) to a glass-stoppered bottle having a capacity of about 200 C.c., add 30 C.c. of bromine decinormal volumetric solution (which is 5 C.c. more than would be required if the carbolic acid in the solution were absolute phenol, the excess being added to promote the formation and separation of tribromophenol), then 5 C.c. of hydrochloric acid, and immediately insert the stopper. Shake the bottle repeatedly in the course of half an hour, then remove the stopper just sufficiently to introduce quickly 5 C.c. of a 20-per-cent. aqueous solution of potassium iodide, being careful that no bromine vapor escapes, and immediately stopper the bottle. Shake the latter thoroughly, remove the stopper and rinse it and the neck of the bottle with a little water, so that the washings may flow into the bottle, and then add, from a burette, sodium hyposulphite decinormal volumetric solution, until the iodine tint is exactly discharged, using towards the end a few drops of starch test-solution as indicator. Note the number of C.c. of sodium hyposulphite decinormal volumetric solution consumed. Deduct this from 30 (the number of C.c. of bromine volumetric solution originally added), and multiply the remainder by 4. The product will, approximately, represent the percentage of absolute Phenol in the Carbolic Acid tested." *U. S.*

Though nearly neutral to test-paper, it combines feebly with some bases; its salts being decomposed by carbonic acid, and those with the alkalies having an alkaline reaction. The potassium carbolate is said to be decomposed even by water. Nitric acid converts it into picric acid, for the manufacture of which it is largely used. It reduces many metallic salts, especially those of silver and copper, and coagulates collodion. Bromine water, added in excess to a weak solution, produces a flocculent white precipitate. This precipitate, which consists of tribromophenol, is so insoluble that it separates even in the most dilute solutions, and affords an extremely delicate test. In 24 hours a solution containing but $\frac{1}{60000}$ of phenol gives the reaction. (Allen, *Com. Org. Analysis*, 2d ed., vol. ii. p. 540.) If an aqueous solution of phenol be gently warmed with ammonium and solution of sodium hypochlorate (avoiding excess), a deep blue color is obtained, which is lasting, but turns to red on the addition of acids. Solutions containing 1 part of phenol in 5000 parts of water react well when 20 C.c. are employed. Much smaller quantities give the reaction after a time. (*Ibid.*, p. 539.) Ferric chloride (avoiding excess) gives a fine violet color, by which 1 part of phenol in 3000 parts of water can be detected. The presence even of neutral salts often interferes with this reaction.

Carbolic acid in solution coagulates albumen and collodion, arrests fermentation, instantly destroys the lower forms of vegetable and animal life, and, in very small proportion, prevents mouldiness in vegetable juices, and protects animal substances against putrefaction.

The substances with which carbolic acid is most likely to be confounded are cresylic acid and creosote, the former, like it, extracted from coal-tar, the latter from wood-tar exclusively. As cresylic acid is incapable of crystallizing at ordinary temperatures, the two cannot be confounded in the solid state, and, as before observed, its presence in the liquid state is of little

consequence, as its virtues are of the same kind, and at least equal. Its boiling point, however, is considerably higher than that of carbolic acid, being about 400°; and it may, therefore, be supposed to be present in any suspected liquid which will not crystallize at any common temperature, or boil under 202° C. (395° F.) to 204° C. (400° F.). It is also distinguished by being less soluble in water, ammonia, glycerin, and solution of soda than is the case with carbolic acid, but it is more soluble in petroleum benzin. (Allen.) (*A. J. P.*, Jan. 1879.) Creosote is distinguished by its lower density, its liquid form, and its higher boiling point; by its insolubility in strong ammonia, or in 6-per-cent. soda solution, as well as its insolubility in pure glycerin (see *Creosotum*); by not coagulating collodion and albumen; and by the different effects on it of strong nitric acid, which with carbolic acid produces pure picric or trinitrophenic acid, and with creosote, oxalic acid, resinous matter, and but a small proportion of picric acid. (Calvert, *Lancet*, 1863, p. 523.) Carbolic acid differs also in having no effect on polarized light.

The commercial carbolic acid powders and liquids all contain not only cresylic acid, but also nearly inactive and valueless neutral tar oils, and it is important to be able to determine the percentage of the *tar acids* and that of simple *tar oils* in a commercial sample. Prof. John Muter (*A. J. P.*, Nov. 1887, p. 581) has worked out a simple method for this, based upon the following four observed facts: 1st, phenol, cresol, and their homologues are completely soluble when shaken up with a 5-per-cent. solution of sodium hydrate; 2d, liquefied phenol and the corresponding cresol are insoluble in a saturated solution of sodium chloride; 3d, in the presence of a sufficient excess of alkali even a largely diluted solution may be boiled down without the slightest appreciable loss of phenol or cresol; 4th, tar oils and naphtalin are only very slightly dissolved by alkali, and may be perfectly removed from the solution by agitating it with benzol.

Prof. E. W. Davy proposes, as a test for carbolic acid, sulpho-molybdic acid, made by dissolving 1 part of molybdic acid in 10 or even 100 parts of pure concentrated sulphuric acid; 3 or 4 drops of this solution are added to the carbolic acid placed on white porcelain: a beautiful blue coloration will be produced upon standing, particularly if the liquid be gently heated; if this reagent is applied to wood creosote in aqueous solution, a brownish-red color is produced. Carbolic acid in creosote may be detected by distilling an aqueous solution of the mixture: the first portion of the distillate will give the reaction for creosote, the last portion that for carbolic acid. (*P. J. Tr.*, June 22, 1878.)

Composition. The view of the composition of carbolic acid now universally accepted is that it is the hydroxyl (OH) derivative of benzene, C_6H_6, and its formula would therefore be C_6H_5,OH. This would ally it to the alcohols, and it may be compared in fact to what are known as *tertiary* alcohols. The *primary* alcohols, like ethyl alcohol, C_2H_5OH, yield corresponding aldehydes and acids on oxidation. The counterpart of these in the aromatic series are the aromatic alcohols, like $C_6H_5.CH_2OH$, which yield benzoic acid, C_6H_5COOH, on oxidation. The name *phenols* has therefore been given to these derivatives in which H of the benzene group is replaced by OH. It is commonly called *carbolic acid*, but its claims to be considered as an acid are very feeble; as, though it combines with salifiable bases, it is incapable of neutralizing the alkalies, does not affect the color of litmus, and may be separated from its combinations with great facility, sometimes, it is asserted, even by water. Shaken in the liquid form with one-fourth of water, and cooled to 40° F., it crystallizes in the form of a hydrate, $C_6H_5,OH + H_2O$, which fuses at 17° C. (62·6° F.).

Medical Properties and Uses. Carbolic acid, in the liquid form, is locally, powerfully irritant and anæsthetic, and, applied undiluted to the skin, causes a sharp pain followed by numbness, and accompanied with a whiteness of the surface, due to the coagulation of albumen. In contact with mucous surfaces it acts in the same way, and if continued long enough may produce a superficial caustic effect. When applied externally or taken internally with sufficient freedom it is a most fatal, rapidly-acting poison. The symptoms are usually developed very rapidly; indeed, death has occurred in two or three minutes, the patient dying in immediate coma and collapse. After small amounts the symptoms, which may be delayed for several minutes, are nausea, cold sweats, marked pallor of the skin, stupor rapidly deepening into complete insensibility, a feeble pulse, which is usually rapid, but has been in some cases much slower than normal, and great disturbance of the breathing. The respirations are usually hurried and shallow, often very irregular, sometimes paroxysmally arrested. There is usually paralysis both of sensation and motion, but in some cases violent epileptiform convulsions have occurred. An almost diagnostic symptom is a blackish coloration of the urine. In severe

poisoning the latter fluid is apt to contain both albumen and tube-casts. Half an ounce of carbolic acid has caused death, and one and a half ounces have been recovered from. When carbolic acid is employed externally the symptoms develop slowly: the dark discoloration of the urine is especially marked, and its presence should be the signal for disuse of the remedy. Death is generally due to paralysis of the respiratory centres; although the heart is powerfully depressed and death may happen by syncope: indeed, carbolic acid is an overpowering, paralyzing poison to all higher tissues. The lesions found after death have been whitish or blackish corrugated spots on the gastric mucous membrane, imperfect coagulability of the blood, and in some instances fatty degeneration of the hepatic cell and of the renal epithelium.

In therapeutic doses carbolic acid has no appreciable effect upon the general system. It is eliminated by all the emunctories, having been found by Lemaire in the breath of animals, but especially escapes through the kidneys, chiefly as a sulphocarbolic and glyco-uronic acid; but, after toxic doses, to some extent unchanged, and probably also in some part oxidized in hydrochinon, oxalic acid, and other educts. As an internal medicament carbolic acid is, at present, used almost solely for its sedative influence upon the gastro-intestinal mucous membrane and its antifermentative action upon the contents of the primæ viæ. It is especially useful in *vomiting* or *diarrhœa* when dependent upon excessive irritability of the gastric or intestinal mucous membrane. In yeasty vomiting, in flatulence, in diarrhœa with offensive passages, in *flatulent dyspepsia*, and in the fermentative diarrhœa connected with *intestinal dyspepsia*, it is very valuable in doses of from one to three drops, not oftener than once in two hours.

By far the most important property of carbolic acid, both as a therapeutic and as a sanative agent, is its destructive influence over the lower grades of organic life, whether vegetable or animal. In a solution containing only one part of the acid in 500 parts of water, it instantly destroys vegetable mould, both plant and spores, and operates with equal destructiveness upon minute or microscopic animalcules. Hoppe-Seyler gives as the result of his observation that all inferior organisms perish in a liquid containing 1 per cent. of the acid. (*Arch. Gén.*, 1873, p. 633.) Rosenbach injected dogs and rabbits with unhealthy pus with and without admixture of carbolic acid, and found that death generally followed in the former case, while with the addition of 5 per cent. of carbolic acid no permanent injury resulted. (*Med. Record*, 1873, p. 427.) Through this power it checks the different proper fermentations, including the putrefactive, and thus acts powerfully as an antiseptic or disinfecting agent. In sufficient concentration it is undoubtedly capable of destroying germs of various diseases. Experiments have determined that, mixed with vaccine matter in the proportion of 2 per cent., it entirely destroys its efficacy, while in a much smaller proportion it has no effect. (*Arch. Gén.*, 1873, p. 632.)

But it is more as a topical than as an internal and systemic remedy that carbolic acid has been used; and its employment in this way has reference in general to its antiseptic and antizymotic property. As regards the mere correction of offensive odor by decomposition or neutralization of the effluvia on which the odor depends, there are other medicines much more energetic than carbolic acid, as chlorine, bromine, and potassium permanganate. Indeed, the probability is that it exercises no deodorizing influence beyond that of merely disguising the smell of the offensive exhalations by its own bad odor. Its real action is upon the cause of the exhalations. Most of these offensive odors depend upon a species of fermentation, the putrefactive for example, and carbolic acid, even in very dilute solution, is powerfully destructive of the organisms which cause fermentations, and consequently acts much more by preventing putrefactive exhalations than by destroying them. A piece of offensive animal matter is less speedily deodorized by carbolic acid than by potassium permanganate; but the former in a short time entirely suppresses the putrefaction, and the matter consequently ceases to smell because it ceases to putrefy; whereas under the mere chemical agent it is only by its constant presence that the odor is prevented, and the putrefaction goes on unchecked.

Through its parasiticidal influence, carbolic acid is highly useful, as a local application, in all the diseases which are connected with or dependent on the presence of microscopic plants or animals. Hence its use in *scabies*, in which it destroys the itch insect, in the different forms of *porrigo* and *trichosis*, in *pityriasis versicolor*, in the *thrush* of infants, and in all cases of minute vermin affecting the human body. In these cases it is applied to the parts affected in weak solution, or in the form of ointment, but care must be taken to avoid poisoning by it. Offensive diphtheritic exudations, putrid ulcers wherever they can be reached, and suppuration with a similar offensive odor, whether on the outer surface, or from the mucous passages, as of the nose, bronchial tubes, external meatus, urinary outlets, the rectum, and, in females, the vagina, afford similar indications for its use. Its use as a vermicide is too dangerous to be justifiable.

It is a very valuable remedy in the treatment of compound fractures, and other surgical or accidental wounds. As success in the so-called *antiseptic* surgery is dependent upon close attention to numerous details, the reader is referred to works upon antiseptic surgery for further information upon the subject. It has been highly recommended as a dentifrice in carious teeth with offensive breath, and to keep the teeth and gums clean from tartar or other morbid deposit consequent upon, or at least connected with, the presence of minute parasitic organisms in these parts. Introduced on cotton, in a concentrated liquid state, into the cavity of a carious tooth, it quickly relieves pain by its local anæsthetic action; but care must be taken to prevent it from touching the lips or the internal surface of the mouth. In cases, too, of morbidly offensive secretion in the axilla and groin, between the toes, etc., it may be used in the form of solution or ointment with hope of benefit.

Independently of its disinfectant properties, it may be employed locally, in weak solution, as a gentle irritant or alterative, or concentrated, as a mild escharotic,* in chronic indolent or flabby *ulcers*, or in those of a specific character, as the syphilitic, in cutaneous eruptions independent of cryptogamic cause, and in non-suppurative chronic or even acute inflammation of the mucous membranes, as in common *angina*. In *scalds* and *burns* it is said to have proved very useful. In concentrated form carbolic acid is a mild caustic, which may be used with advantage in the treatment of *warts*, *corns*, and other epidermal growths.

The stomach pump or the india-rubber tube siphon should be employed in carbolic acid poisoning, after the administration of the antidote, the benumbing of the stomach being such that emetics usually will not act. M. Husemann recommended as an antidote the *saccharate of lime*, prepared by dissolving 16 parts of sugar in 40 parts of distilled water, adding 5 parts of caustic lime, digesting it three days with occasional agitation, then filtering and evaporating to dryness. The resulting saccharate should be given in solution. (*Journ. de Pharm.*, 1873, p. 222.) The discovery, however, of Baumann and Hueter that the *soluble sulphates*, especially the *sodium sulphate*, form with carbolic acid harmless sulpho-carbolates, and are capable of neutralizing the poison even after its absorption into the blood, has been abundantly confirmed by Dr. David Cerna and others, and in *sulphuric acid* and *the innocuous soluble sulphates* we have very certain antidotes, which should be given freely, promptly, and continuously.

Of the tests for carbolic acid in cases of suspected poisoning by this substance, the three most characteristic are: the ammonia and hypochlorite test, the test with ferric chloride, and the bromine test. One part of carbolic acid in 5000 of water may be shown by adding to the solution first about one-quarter its volume of ammonium hydrate and then a small quantity of sodium hypochlorite solution, when a blue color will appear. One part of phenol in 3000 of water can be detected by the addition of a solution of ferric chloride, when a fine violet color will develop, although the color is often interfered with in complex liquid mixtures. The most satisfactory test is that with bromine water. A whitish precipitate of tribromphenol will form even in very dilute solutions on standing. One part in 60,000 can be detected in this way. The precipitate is insoluble in water and acid liquids, but soluble in alkalies, ether, and absolute alcohol.

The dose of carbolic acid is one to three grains (0·064–0·19 Gm.), or of the acid in its concentrated liquid form one to three drops (0·06–0·18 C.c.), which may be given in half a fluidounce or a fluidounce of sweetened water. An excellent menstruum is glycerin, which dissolves it in all proportions; and a preparation is at present official in the British Ph., consisting of an ounce of carbolic acid dissolved in four fluidounces of glycerin, of which about four minims represent a grain of the acid. From this solution formulas may be readily prepared, either for internal or for external use, by diluting it with water. (See *Glyceritum Acidi Carbolici.*)

For external use the strength varies greatly according to the object desired. When applied with a view to its superficial escharotic action, as in gangrenous or specific ulcers, it may be used in the solid state properly comminuted, or in the strongest liquid form. In this condition it may be readily obtained by placing the bottle containing it in hot water. Bufalini recommends its combination with camphor, under the name of *Camphorated Phenol*, asserting that the camphor moderates the caustic and disorganizing action of the phenol without destroying its useful effects; he prepares it by mixing one part of carbolic acid with two parts of

* Dr. Robert Battey, of Rome, Ga., in the *Amer. Pract.*, Feb. 1877, suggests a combination with iodine, as a uterine escharotic and alterative, under the name of *Iodized Phenol*, prepared by "gently warming one ounce of crystallized carbolic acid with half an ounce of iodine." This may be diluted, if necessary, with an equal bulk of glycerin. Under the name of *Iodated Phenol* a weaker preparation has been used, made by dissolving 4 grains each of iodine and carbolic acid in 10 drachms of glycerin. *A. J. P.*, 1886, p. 14.

camphor, allowing the mixture to stand some hours, and purifying by washing with water; it is a liquid of reddish-yellow color, having the smell of camphor, insoluble in water, and soluble in alcohol and ether. For the skin affections one part of the acid may be dissolved in one hundred or two hundred parts of water; or the impure liquid acid may be used, diluted in the same proportion. M. Bazin uses a solution of one part in forty parts of acetic acid of 8° B. and 100 of water, in *tetter* and *psora*, and states that a single application will destroy the itch insect. A solution containing a grain to the fluidounce of water may be used for application, in the form of *spray*, to the fauces, larynx, and bronchial tubes, by means of the atomizer; and the strength may be increased up to four or five grains or more to the fluidounce.

Various fabrics are impregnated with carbolic acid for surgical use.* Prof. *Lister's gauze* may be made by soaking a loose cotton cloth with a mixture of 5 parts resin, 7 parts paraffin, and 1 part carbolic acid. Prof. Bruns improves upon this, making a more flexible dressing, by dissolving 400 grammes of powdered resin in 2 litres of alcohol, adding 40 grammes of castor oil and 100 grammes of carbolic acid; this will impregnate 2 pounds of the gauze, which is to be dried by spreading it out in the air. (See also Lund's process, *A. J. P.*, Feb. 1874.) *Carbolized jute* may be made by Rosenwasser's process by soaking in a percolator 1 pound of jute with a solution of crystallized carbolic acid 700 grains, paraffin 700 grains, resin 2800 grains, benzin 3 pints. (*Am. Journ. Med. Sci.*, 1879, p. 458. See also *N. R.*, April, 1879, and April, 1880.) For burns and scalds 1 part of carbolic acid in 6 parts of olive oil may be applied on lint. For the dressing of cancerous and other foul ulcers, a cerate (five grains to the ounce) may be used. There is an official ointment. A carbolic acid paper, used in packing fresh meats, in order to preserve them, may be prepared by melting 5 parts of stearin with a gentle heat, stirring in thoroughly 2 parts of carbolic acid, adding 5 parts of melted paraffin, stirring the mixture till it cools, and finally melting, and applying in the usual manner to the paper in quires. (*Chemist and Druggist*, Dec. 1871.)

The impure liquid acid sold in the shops usually contains from 70 to 90 per cent. of carbolic and cresylic acids jointly (*Squibb*), and, as the latter acid is quite equal to the former in disinfecting power, yields, if dissolved in water in the proportion of 1 to 80 parts, a solution equivalent on the average to that produced by dissolving 1 part of the pure acid in 100 parts of water.

ACIDUM CARBOLICUM CRUDUM. U. S. Crude Carbolic Acid.

(ĂC'Ĭ-DŬM CĂR-BŎL'Ĭ-CŬM CRŪ'DŬM.)

"A liquid consisting of various constituents of coal-tar, chiefly cresol and phenol, obtained by fractional distillation." *U. S.*

Acide phénique cru, *Fr.*; Rohe Carbosäure, *G.*

With great propriety, we think, the revisers of the U. S. Pharmacopœia, 1880, gave a distinct heading to this form of carbolic acid, and directed it to be used only externally; for, while its impurity, and its more or less uncertain composition and strength, unfit it for internal employment, it is equally efficacious with the purer acid as a local remedy and disinfectant. Crude carbolic acid is officially described as "a nearly colorless, or reddish, or brownish-red liquid, of a strongly empyreumatic and creosote-like odor; having a benumbing, blanching, and caustic effect upon the skin or mucous membrane; and gradually turning darker on exposure to air and light. The aqueous solution of Crude Carbolic Acid has a slightly acid reaction on litmus paper. In an aqueous solution of the Acid, bromine water produces a white precipitate. Crude Carbolic Acid should not be soluble in less than 15 parts of water at 15° C. (59° F.), and the aqueous solution should not have an alkaline reaction (absence of *alkalies*). If 50 volumes of the Acid be thoroughly agitated with 950 volumes of water, in a capacious vessel, on allowing the mixture to separate, the undissolved portion should not exceed 5 volumes, or 10 per cent. by volume of the acid (limit of other *less soluble constituents of coal-tar*)." *U. S.*

ACIDUM CARBOLICUM LIQUEFACTUM. Br. Liquefied Phenol.

(ĂC'Ĭ-DŬM CĂR-BŎL'Ĭ-CŬM LĬQ-UĘ-FĂC'TŬM.)

"Phenol to which distilled water has been added in the proportion of ten parts by weight of the water to one hundred parts by weight of the Phenol. It is commonly termed liquefied carbolic acid." *Br.*

This official of the British Pharmacopœia (practically a 90 per cent. phenol) is a valuable liquid. Its introduction was doubtless due to the habitual use of the same preparation in dispensing, so as to avoid weighing the acid.

* See *Carbasus Carbolata*, N. F.

It is described as "a liquid at first colorless, but usually acquiring a pinkish hue. It forms a clear solution on the addition of 18 to 27 per cent. of *water* at 60° F. (15·5° C.). Specific gravity 1·064 to 1·069 at 60° F. (15·5° C.). Boiling point gradually rising to a temperature not higher than 359·6° F. (182° C.)." *Br.* Peter Boa prefers to replace a portion of the water used for liquefying the phenol with alcohol, and he found the following mixture to remain fluid even at a temperature of 40° F.: 100 parts of phenol, 7½ parts of water, and 2½ parts of alcohol. Dose, two minims (0·12 C.c.), practically equivalent to one grain of the acid.

ACIDUM CHROMICUM. U. S., Br. Chromic Acid.

CrO_3; 99·88. (ĂC′I-DŬM ĈHRŌ′MI-CŬM.) CrO_3; 100·4.

"Chromic Acid should be kept in glass stoppered bottles, and great caution should be observed to avoid bringing it in contact with organic substances, such as cork, tannic acid, sugar, alcohol, etc., as dangerous accidents are liable to result." *U. S.* "Chromic Anhydride, CrO_3, commonly termed chromic acid, is produced by the interaction of sulphuric acid and potassium bichromate." *Br.*

Chromic Anhydride, Chromium Trioxide, Anhydrous Chromic Acid; Acide chromique, *Fr.*; Chromsäure, *G.*

This is not a true acid, but an acid anhydride. It may be obtained by the process official in the former British Pharmacopœia: "Bichromate of Potassium, 30 ounces (av.); Sulphuric Acid, 57 fluidounces (Imp. meas.); Distilled Water, a sufficiency. Dissolve the bichromate of potassium in a mixture of 50 fluidounces (Imp. meas.) of the water and 42 fluidounces (Imp. meas.) of the acid. Set aside for twelve hours, and decant the liquor from the crystals of acid sulphate of potassium that have separated. Heat the liquor to about 185° F. (85° C.), and add the remainder of the acid, and water sufficient to just redissolve any crystals of chromic acid that may have been formed. Allow to cool, collect and drain the crystals, and dry them on porous tiles at a temperature not exceeding 100° F. (37°·8 C.) in an air-bath. From the mother liquor more crystals may be obtained on evaporation." *Br.*

This process yields crystals which are more or less contaminated with sulphuric acid. Dr. Vulpius (*Archiv d. Pharm.*, 1886, p. 964) shows that commercial chromic acid sometimes contains as much as 7 per cent. of sulphuric acid, and that pure chromic acid is not scarlet in color, but dark brown-red and steel-glistening, and not deliquescent in ordinary air.

The best yield of pure crystals is said to be according to the method of Zettnow (*Pogg. Ann.*, cxliii. 471), in which 300 Gm. of potassium bichromate are mixed with 500 C.c. of water, and 420 C.c. of concentrated sulphuric acid added, and the mixture allowed to stand for twelve hours in order that the acid potassium sulphate may crystallize out. The mother-liquor is then heated to from 80° to 90°, and 150 C.c. of sulphuric acid added, together with enough water to dissolve the crystals of trioxide which at first separate out. After standing for twelve hours the liquid is poured off from the crystals which have separated, and a second and a third crop may be obtained by concentration. The crystals having been drained upon a porous plate and washed with pure nitric acid, 1·46 gravity, are dried in a current of warm air. For a method by M. Duviller, in which barium chromate is treated by nitric acid, and chromic acid crystallized out of the mother-liquor, see *A. J. P.*, 1873, p. 23.

Properties. Chromic acid, as ordinarily seen in commerce, is in the form of anhydrous, acicular crystals, of a brilliant crimson red color and an acid metallic taste, deliquescent, and very soluble in water, forming an orange-red solution. The requirements of the U. S. Pharmacopœia of 1890 are that even traces of sulphuric acid shall be absent, and that the color of the crystals be not scarlet. "Small, needle-shaped crystals, or rhombic prisms, of a dark purplish-red color and metallic lustre; odorless; destructive to animal and vegetable tissues; deliquescent in moist air. Very soluble in water, forming an orange-red solution. When brought in contact with alcohol, ether, glycerin, and other organic solvents, decomposition takes place, sometimes with dangerous violence. When Chromic Acid is heated, its color darkens, and finally becomes black, but is restored on cooling. At 192° to 193° C. (377·6° to 379·4° F.) it fuses to a reddish-brown liquid, which, on cooling, forms a dark red, brittle mass (often enclosing cavities filled with crystals), furnishing a scarlet powder. Above 250° C. (482° F.) it begins to decompose into green chromic oxide and free oxygen, and, after protracted heating, leaves a residue of pure chromic oxide, which should yield nothing soluble to water." *U. S.* "It is very soluble in *water* and in *ether*. Warmed with *hydrochloric acid*, chlorine is evolved. Mixed with cold *alcohol* (90 per cent.), aldehyde is produced, and a green residue remains. If placed in contact with relatively small proportions of either *alcohol* (90 per cent.), *ether*, *glycerin*, or some other organic matters, sudden combustion or explosion may ensue. 1 gramme dissolved in 50

cubic centimetres of *water* and acidulated with *hydrochloric acid* should afford only a slight opalescence with *solution of barium chloride* (absence of more than traces of sulphates)." *Br.*

Chromic acid is a teroxide of the metal chromium, having the formula CrO_3. At a heat above the melting point it gives off half its oxygen, and is converted into the green sesquioxide, Cr_2O_3. It is a powerful oxidizing and bleaching material, and gives up its oxygen with great facility to organic matter. The oxidation of weaker alcohol is attended with the production of aldehyde, recognized by the odor; that of stronger alcohol, by inflaming. "A solution of 1 Gm. of Chromic Acid in 100 C.c. of water previously acidulated with a few C.c. of hydrochloric acid should not be rendered turbid on the addition of 1 C.c. of barium chloride test-solution (absence of *sulphuric acid*)." *U. S.*

Medical Properties and Uses. As an antiseptic and disinfectant, chromic acid is asserted by Dr. John Dougal (*Lancet*, Dec. 16, 1871), who founds his conclusions on experiment, to be second to none, and in some respects to surpass even carbolic acid. A piece of fresh beef immersed in a solution of chromic acid containing only 1 part in 2000 of water became in two days quite black, in six as hard as wood, and at the end of three months remained perfectly free from mould or taint. It is a powerful coagulant of albumen, being, according to Dougal, 10 times stronger than carbolic acid, 15 times stronger than nitric acid, and 20 times stronger than corrosive sublimate. It is, therefore, one of the best tests for albumen. Besides coagulating albuminous substances, it oxidizes decaying organic matter, combines with and neutralizes the escaping ammonia, and decomposes the hydrogen sulphide, reducing it to water and free sulphur. It is also one of the most powerfully destructive agents to inferior organic life, greatly exceeding carbolic acid in this respect. Chromic acid has been used medically only as an escharotic, in which capacity it acts by rapidly oxidizing and thus decomposing the tissues, while by the loss of one-half its oxygen it is itself converted into the inert sesquioxide. It was first employed as a caustic by Prof. Sigmund, of Vienna, on the recommendation of Dr. Heller. Used in substance, made into a paste with water, its action is exceedingly slow and gradual, but deeply penetrating. In saturated solution its action is less penetrating and less gradual. By using a solution more or less dilute, the effect may be graduated according to the degree desired. Prof. Sigmund commends concentrated solution for the destruction of *condylomata*. But caution is necessary, as it may give rise to a deep slough if too largely applied; and, according to M. Gubler, patients have been poisoned, through absorption, by its too extensive application. (*Ed. Med. Journ.*, Sept. 1871, p. 281.) It has been recommended to destroy growths in the mouth and larynx, and, from its combined escharotic and disinfecting properties, in *hospital gangrene*, *scorbutic or gangrenous ulcers* of the mouth, *phagedænic ulcers*, *bites of rabid animals*, *poisoned wounds*, etc.; as a wash to arrest fetid discharges; as an injection in *ozæna*, *leucorrhœa*, and *gonorrhœa*; to prevent suppuration and putrefaction in wounds, etc.; and for the disinfection of cholera and fever stools, as well as for correcting fetid odors from all sources. The occasional application of a five per cent. solution of chromic acid has been found in Prussia very useful in the treatment of *sweating* or *tender feet*, amongst the soldiery. Care should be taken not to prescribe chromic acid in combination with glycerin, or any substance which will cause it to part rapidly with its oxygen: a compounded prescription containing 8 grains of chromic acid and 1 drachm of glycerin exploded violently. (*Zeitschr. Oester. Apoth. Verein*, June 1, 1875.) It is best to use a simple aqueous solution. The solution, or even the pure acid, is used by gynæcologists to destroy intra-uterine growths; but great care is requisite.

Chromic acid is very rarely, if ever, used internally; if employed, the dose should not exceed one-quarter of a grain (0·016 Gm.).

ACIDUM CITRICUM. U. S., Br. Citric Acid.

$H_3C_6H_5O_7 + H_2O$; 209·50. (ĂÇ'Ĭ-DŬM CĪ'TRĬ-CŬM.) $H_3C_6H_5O_7, H_2O$; 210.

"An organic acid, usually prepared from lemon-juice." *U. S.* "Citric Acid, or hydrogen citrate, $C_3H_4.OH.(COOH)_3, H_2O$, may be obtained from the juice of the fruit of various species of Citrus." *Br.*

Acidum Citri, s. Limonis, s. Limonum, s. Limonorum; Acide citrique, Acide du Citron, *Fr.;* Citronensäure, Citronsäure, *G.;* Acido citrico, *It., Sp.*

Citric acid is the peculiar acid to which limes and lemons owe their sourness. It is present also in the juice of other fruits, such as the cranberry, the red whortleberry, the berry of the bittersweet, the red gooseberry, the currant, the strawberry, the raspberry, the tamarind, and the red elderberry (fruit of *Sambucus racemosa rubra*). The latter berry contains citric acid so abundantly that it has been proposed as a source of the acid by M. Thibierge, of Versailles.

It is contained also largely in the fruit of *Cyphomandra betacea*, a solanaceous plant, indigenous in Mexico, Peru, and other parts of South America, where it is called *tomato de la paz*. (*Journ. de Pharm.*, Oct. 1869, p. 305.) The commercial source of citric acid is lime-, lemon-, and bergamot-juice; large quantities of *lime-juice* are made in Sicily, concentrated, and exported to England and the United States.*

The acid is extracted from lemon- or lime-juice by a very simple process, for which we are indebted to Scheele; it is one requiring some careful manipulation. The boiling juice is first completely saturated with calcium carbonate (chalk or whiting) in fine powder, and the calcium citrate thus formed is allowed to subside. This is then washed repeatedly with water, and decomposed by dilute sulphuric acid. An insoluble calcium sulphate is precipitated, and the disengaged citric acid remains in solution. This is carefully concentrated in leaden boilers until a pellicle begins to form, when it is transferred to other vessels to cool and crystallize.

The commercial lemon-juices contain free citric acid; free acids other than citric; citrates, salts of organic acids other than citric; salts of inorganic acids; and albuminous, mucilaginous, saccharine, and other indifferent bodies. Spirit is frequently added as a preservative, and mineral acids are not uncommonly employed as adulterants. Verjuice has also been used for the purpose (*Allen*). See also Montserrat lime-juice, *P. J. Tr.*, 1883, p. 606, and notes on manufacture, etc., *N. R.*, 1883, p. 47. In the U. S. Pharmacopœia, very properly, no process is given for making citric acid, as it is always purchased from the manufacturing chemist. The British Pharmacopœia gives the following process for preparing it:

"Take of Lemon Juice *four pints* [Imperial measure]; Prepared Chalk *four ounces and a half* [avoirdupois]; Sulphuric Acid *two fluidounces and a half;* Distilled Water *a sufficiency*. Heat the Lemon Juice to its boiling point, and add the Chalk by degrees till there is no more effervescence. Collect the deposit on a calico filter, and wash it with hot water till the filtered liquor passes from it colorless. Mix the deposit with a pint [Imp. meas.] of Distilled Water, and gradually add the Sulphuric Acid previously diluted with a pint and a half [Imp. meas.] of Distilled Water. Boil gently for half an hour, keeping the mixture constantly stirred. Separate the acid solution by filtration, wash the insoluble matter with a little Distilled Water, and add the washings to the solution. Concentrate this solution to the density of 1·21, then allow it to cool, and after twenty-four hours decant the liquor from the crystals of sulphate of calcium which will have formed; further concentrate the liquor until a film forms on its surface, and set it aside to cool and crystallize. Purify the crystals, if necessary, by recrystallization." *Br.*

Preparation on the Large Scale. The juice is placed in a large vat, closed at top, and is saturated with whiting (calcium carbonate). Carbonic acid gas is thus evolved, which passes out by an exit-pipe, and may be used in the manufacture of sodium bicarbonate; while calcium citrate precipitates. The supernatant liquor, containing much extractive matter, is drawn off; and the calcium citrate is decomposed by dilute sulphuric acid, liberating the citric acid, and precipitating the lime as a sulphate. The mixture of citric acid and calcium sulphate is run off into a wooden filter-back, lined with lead, furnished with a perforated false bottom, and lined throughout with stout twilled flannel. The solution of citric acid passes off through a pipe leading from the bottom of the back to suitable reservoirs.

The sulphate is washed until it becomes tasteless, and the washings are run off into the same reservoirs. The filtered acid solution is then concentrated by evaporation in wooden vessels

* The composition of some of these commercial lime-juices is given by Allen (*Com. Org. Analysis*, 2d ed., vol. i. p. 459), as follows:

	Density.	Oz. Free Acid per gallon.	Oz. Combined Org. Acid per gallon.
Lime-juice:			
Raw Sicilian	. . . . .	6 to 9	0·85
Raw English	1·04 to 1·05	11 to 13	0·3
Concentrated	1·20 to 1·25	56 to 72	6 to 8
Bergamot-juice:			
Concentrated	1·22 to 1·25	47 to 55	7 to 8
Lemon-juice:

lined with lead, through which steam is made to pass by means of coiled lead pipes. As citric acid is liable to decomposition if subjected to too high a temperature, the use of the vacuum pan is highly advantageous in concentrating the solution. When the liquor is sufficiently concentrated, it is transferred to cylindrical sheet-lead vessels, placed in a warm situation, to crystallize. The crystals at first obtained are colored. In order to purify them, they are redissolved in a small quantity of water, with the assistance of heat, and the solution is digested with purified animal charcoal, filtered, and recrystallized. The crystals, after having been washed and drained, are dried on wooden trays lined with sheet-lead, in a room heated by steam.

The calcium citrate of the above process should be decomposed without any delay; for, if kept, it will undergo fermentation, with the effect of destroying the citric acid. According to Personne, the products of this fermentation are acetic and butyric acids; carbonic acid and hydrogen being evolved. It is desirable to have a slight excess of sulphuric acid, as this rather favors than otherwise the crystallization of the citric acid. It is found necessary, also, to add occasionally a small proportion of sulphuric acid to the citric acid liquor, during the progress of its concentration. According to J. Carter Bell (*N. R.*, 1880, p. 274), the concentrated juice contains from sixty-four to ninety-six ounces of citric acid to the imperial gallon. The more recent the juice the better the quality. That which is stale will sometimes be quite sour, without containing any citric acid, in consequence of having undergone the acetous fermentation.

Citric acid by fermentation of carbohydrates is claimed by German patent No. 72,957 of 1893, and species of citromyces are especially mentioned as bringing about this fermentation. This patent is now supplemented by a new claim (German patent 91,891 of 1897), based upon the discovery that the same result may be obtained by means of *Mucor pyroformis*. The latter fungus is found on putrefying fruit, especially on pears and apples; its spore carriers grow only in a moist atmosphere and form long white filaments, terminated by brownish-black heads. It can be readily obtained in pure culture by sowing the spores in a suitable medium, such as sugar solutions, beer-wort, steamed rice, starch-paste, etc., the ordinary room temperature being favorable for its growth. The solution becomes acid from the formation of citric acid. (*Journ. Soc. Chem. Ind.*, June 30, 1897; see also *P. J. Tr.*, 1893, 182, and *P. J. Tr.*, 1894, 893.)

Properties. "Colorless, translucent, right-rhombic prisms; odorless; having an agreeable, purely acid taste; efflorescent in warm air, and deliquescent when exposed to moist air." *U. S.* Its sp. gr. is 1·6. When heated, it dissolves in its water of crystallization, and at a higher temperature undergoes decomposition, becoming yellow or brown, and forming a very sour syrupy liquid, which is uncrystallizable. By destructive distillation it gives rise at first to water and *aconitic acid*, $C_6H_6O_6$, and on further heating it is decomposed into carbon dioxide, acetone, and *itaconic* and *citraconic acids*, both of the formula $C_5H_6O_4$. "When heated to about 75° C. (167° F.), the acid begins to lose its water of crystallization; at about 135° C. (275° F.) it becomes anhydrous, and melts between 135° and 152° C. (275° and 305·6° F.). When slowly ignited, it is gradually decomposed without emitting the odor of burning sugar (difference from *tartaric acid*), and is finally consumed without leaving more than 0·05 per cent. of residue." *U. S.*

Citric acid is "soluble, at 15° C. (59° F.), in 0·63 part of water, and in 1·61 parts of alcohol; in about 0·4 part of boiling water, and in 1·43 parts of boiling alcohol; also soluble in 18 parts of ether." *U. S.* "Soluble in three-fourths of its weight of cold or in half its weight of boiling *water*, somewhat less soluble in *alcohol* (90 per cent.), and soluble to a slight extent in *ether*. The aqueous solution made by dissolving 35 grains of the Acid in 1 ounce (or 1 gramme in 12½ cubic centimetres) of *water* resembles, in acidity, an average specimen of Lemon Juice," *Br.*; but is nearly insoluble in chloroform, benzol, and benzin. A weak solution of it has an agreeable taste, but cannot be kept, as it undergoes spontaneous decomposition. It is incompatible with alkaline solutions, whether pure or carbonated, converting them into citrates; also with the earthy and metallic carbonates, most acetates, the alkaline sulphides, and soaps. It is characterized by its taste, by the shape of its crystals, and by forming an insoluble salt with lime-water when heated, and a deliquescent one with potassa. If sulphuric acid be present the acid will be hygroscopic, and the precipitate by lead acetate will not be entirely soluble in nitric acid; the insoluble portion being lead sulphate. Sometimes crystals of tartaric acid are substituted for or mixed with the citric, or the two acids may be mixed in powder, a fraud which is readily detected by adding a solution of potash to that of the suspected acids, when, if tartaric acid be present, a crystalline precipitate of potassium bitar-

trate (cream of tartar) will be formed: "On adding 1 C.c. of an aqueous solution (1 in 10) of the Acid to 50 C.c. of calcium hydrate test-solution (or so much more of the latter that the mixture has an alkaline reaction), the liquid remains clear. Upon boiling this for about one minute, it becomes opaque through the precipitation of calcium citrate, which redissolves on cooling. If 1 Gm. of the powdered Acid be dissolved in 5 C.c. of a cold solution (1 in 3) of potassium acetate, the liquid should remain clear, even after the addition of an equal volume of alcohol (absence of *tartaric* or *oxalic acid*)."* *U. S.* See Spiller, *Journal Chemical Society*, x. 110. A still more delicate method of detecting tartaric acid is to digest the suspected acid with ferric hydrate in a test-tube, afterwards to raise the heat slowly to the boiling point, and, having allowed the excess of hydrate to subside, to decant the clear liquid, and evaporate it to a syrupy consistence. If the acid be pure, the liquid remains limpid, and of a fine red color; if contaminated with tartaric acid, even to the extent of only one per cent., it becomes cloudy, and deposits tartrate. Another test is potassium permanganate, of which an alkaline solution is without action on citric acid; while under the influence of tartaric acid the manganese peroxide is deposited. "On mixing 10 C.c. of a 10-per-cent. aqueous solution of the Acid with a quantity of ammonia water insufficient to neutralize it completely, and adding to one-half of this liquid 1 C.c. of ammonium oxalate test-solution, it should remain clear (absence of *calcium*). The other half, mixed with a few C.c. of hydrogen sulphide test-solution, should not deposit a colored precipitate, nor acquire more than a faintly brownish-yellow tint (limit of *metallic impurities*). On treating 10 C.c. of a 1-per-cent. aqueous solution of the Acid with 1 C.c. of barium chloride test-solution and a few drops of hydrochloric acid, the liquid should not show any turbidity within five minutes (limit of *sulphuric acid*). To neutralize 3·5 Gm. of Citric Acid should require 50 C.c. of potassium hydrate volumetric solution (each C.c. corresponding to 2 per cent. of the pure acid), phenolphtalein being used as indicator." *U. S.* "Each gramme dissolved in *water* should require for neutralization 14·3 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no characteristic reaction with the tests for copper or iron, and only very slight reactions with those for calcium or sulphates. Its solutions should not contain any metallic particles. 10 grammes dissolved in 20 cubic centimetres of *water*, neutralized with *solution of ammonia*, and sufficient of a saturated aqueous solution of *hydrogen sulphide* added to produce 100 cubic centimetres of liquid, no darkening of color should result after 5 minutes (absence of lead). One drop of *solution of ferrous sulphate*, then a few drops of *solution of hydrogen peroxide*, and finally an excess of *solution of potassium hydroxide*, added to an aqueous solution of the Acid, no purple or even light violet coloration should result (absence of tartaric acid). Or 1 gramme placed in a test-tube with 5 cubic centimetres of *solution of ammonium molybdate*, 2 or 3 drops of *solution of hydrogen peroxide* being added, should not afford a bluish coloration after the tube has been shaken and placed in boiling water for ten minutes (absence of tartaric acid; but the presence of any metallic particles gives rise to a similar coloration). On incineration with free access of air, it should not yield more than 0·05 per cent. of ash." *Br.* Lead is frequently found in the metallic state in citric acid in small quantity, and this arises from small portions being rubbed off in breaking off the crystals from the crystallizing-vats. The presence of lead or copper may be detected as above, or by igniting in a porcelain crucible a small quantity of the acid, dissolving the ash in a few drops of nitric acid, diluting largely, and passing hydrogen sulphide through it; a black precipitate indicating the impurity. Some interesting observations about the presence of lead in citric acid and citrates are recorded by F. W. Haussmann in *A. J. P.*, 1894, 173.

Composition. The formula of the anhydrous acid is $C_6H_5O_7H_3$. It is a tribasic acid, and may therefore yield three classes of citrates according as one, two, or three atoms of hydrogen are replaced by metal, the first two classes being acid citrates, and the third class neutral citrates. When crystallized from its solution by cooling, it contains one molecule of water. Crystals of the formula $(C_6H_8O_7)_2 + H_2O$ have also been formed. (Flückiger, *Pharm. Chem.*, 1879, p. 157.) H. Witter (*Pharm. Centralhalle*, 1892, 1003) has obtained anhydrous citric acid by heating aqueous solutions of the hydrated acid to 130° C. If citric acid be heated until all its water of crystallization has been driven off, there will be produced *aconitic acid*,

* *Pusch's Method of Determining the Presence of Tartaric Acid in Citric Acid.* 1 gramme of powdered citric acid is added to 10 grammes of strong, pure, colorless, sulphuric acid in a dry test-tube, and the tube is then immersed in boiling water for an hour. The citric acid dissolves with frothing and evolution of gas, and a lemon-colored liquid is formed, which undergoes no change within half an hour if the sample be pure; but if as much as one-half per cent. of tartaric acid be present, the color is brownish and reddish-brown an hour afterward. (*Archiv d. Pharm.*, xxii. 316.)

($C_6H_3O_6H_3$), which also exists naturally in aconite, larkspur, black hellebore, equisetum, yarrow, and other plants.*

Medical Properties, etc. Citric acid acts as a poison chiefly if not solely by irritating the gastro-intestinal mucous membrane. It is, however, much less irritant than tartaric acid, and, so far as we know, no death has been caused by it. The action of therapeutic doses upon the system is not decided. In *scurvy*, citric acid is probably of some value, but is very inferior to lemon-juice. It is eliminated by the kidneys, and, as first stated by Bence Jones, when given in sufficient quantities renders the urine acid. In a free state it is very rarely, if ever, used internally, except as an imperfect substitute for lemon-juice. When added in the quantity of nine drachms and a half to a pint of distilled water, it forms a solution of the average strength of lemon-juice. Of this solution, or of lemon-juice, a scruple of potassium bicarbonate saturates three fluidrachms and a half; a scruple of potassium carbonate, four fluidrachms; and a scruple of ammonium carbonate, six fluidrachms. Half a fluidounce of lemon-juice, or of an equivalent solution of citric acid, when saturated, is considered a dose. An agreeable substitute for lemonade may be made by dissolving from two to four parts of the acid, mixed with sugar and a little oil of lemon, in nine hundred parts of water; or a scruple of the acid may be dissolved in a pint of water, and sweetened with sugar which has been rubbed on fresh lemon-peel. The dose of the acid may be stated at from five to thirty grains (0·32–1·94 Gm.).

ACIDUM GALLICUM. U. S., Br. Gallic Acid.

$HC_7H_5O_5 + H_2O$; 187·55. (ĂS'Ĭ-DŬM GĂL'LĬ-CŬM.) $HC_7H_5O_5, H_2O$: 188.

"An organic acid, usually prepared from tannic acid." *U. S.* "A trihydroxybenzoic acid, $C_6H_2(OH)_3COOH,H_2O$. It may be prepared by the action of diluted sulphuric acid on tannic acid." *Br.*

Acide gallique, *Fr.*; Gallussäure, *G.*; Trioxybenzoic Acid, Dioxysalicylic Acid, Trihydroxybenzoic Acid.

The former British Pharmacopœia process for making gallic acid is as follows: "Boil one part of coarsely powdered galls with four fluid parts of diluted sulphuric acid for half an hour, then strain through calico while hot; collect the crystals that are deposited on cooling, and purify these with animal charcoal and repeated crystallization."

The process based on the influence of sulphuric acid in favoring the change of tannic into gallic acid has the merit of requiring less time than former processes.

The U. S. 1870 process† is founded upon the fact that when galls in infusion, or in the state of moistened powder, are exposed to the air, their tannic acid is gradually converted into gallic acid. The gallic acid, being freely soluble in boiling but very sparingly in cold water, is extracted from the altered galls by decoction, and is deposited as the water cools. A repetition of the solution and deposition renders the acid more pure; but it cannot be obtained wholly colorless unless by the aid of animal charcoal. There are few processes in which it is more necessary that the animal charcoal should be purified. The presence of the slightest quantity of ferric salt interferes with the bleaching of the acid; and it is even advisable to examine the filtering paper, lest it may contain sufficient of this substance to vitiate the results of the process. The first crop of crystals in the process retains a very large proportion of water; and it will be found convenient to subject them to strong expression between folds of bibulous paper.

The elder Robiquet first suggested that galls contained a principle capable of converting tannic into gallic acid, with the presence of water, and in the absence of atmospheric air. M. Laroque proved that this principle acts as a ferment, and that the change referred to is the result of a *gallic acid fermentation* in the galls. M. Edmond Robiquet showed that galls contain *pectose* and *pectase*, the former of which, according to the experiments of M. Frémy, is the principle out of which pectin is formed in plants, and the latter a peculiar ferment which effects the transformation. He believed that in galls the pectase, aided by a proper temperature and the presence of water, changed not only pectose into pectin, but also tannic into gallic acid. Strecker previously advanced the opinion that tannic acid was a combination of gallic acid and sugar, the latter of which is destroyed in the process for procuring gallic acid, which is thus simply set free from the combination. M. E. Robiquet admitted the occasional transformation of tannic acid into gallic acid and sugar, but did not believe that the sugar pre-existed as such in the tannin. (*Journ. de Pharm.*, 3e sér., xxiii. 241.) Wittstein, in endeav-

* According to Hentschel, aconitic acid is best obtained by boiling for six hours 100 Gm. of citric acid with 50 Gm. of water mixed with 100 Gm. of pure sulphuric acid in a flask provided with a reverse condenser. Upon cooling the flask a solid cake of aconitic acid is found, which may be purified by mixing with strong hydrochloric acid, and washing until free from sulphuric acid; colorless, shining crystals are obtained. (*Archiv d. Pharm.*, 1887, p. 357.)

† See U. S. Dispensatory, 15th ed., p. 60.

oring to obtain gallic acid from *Chinese galls* by forming them into a paste with water, found that but a very small proportion of the acid was generated at the end of six weeks. Thinking that this might have resulted from the want of the ferment in the Chinese galls, he added to these one-eighth of their weight of common galls, and at the end of three weeks obtained an amount of gallic acid nearly equal to one-half the weight of the galls employed. The same result, though more slowly, followed the addition of yeast to the Chinese galls. Wittstein obtained both carbonic acid and alcohol as products of this operation, thus favoring the views of Strecker as to the constitution of tannic acid. And the idea that tannin was a glucoside convertible through exposure of galls to the air, or more rapidly by sulphuric acid, into glucose and gallic acid, was accepted without qualification, until Schiff (*Deut. Chem. Ges. Ber.*, iv. 231, 967, and *Bull. Soc. Chem.* [2], xviii. 23) proved that although crude tannic acid contains glucose, it is possible to separate a large quantity of the glucose without destroying the tannic acid. He proposes that *pure tannic acid* be called *digallic acid*, and that the term *tannin* be applied to natural tannin, *i.e.*, the *glucoside* of digallic or pure tannic acid, for when natural tannin is boiled with dilute mineral acids, or subjected to the influence of a nitrogenous ferment, it splits into digallic acid and glucose, $C_{34}H_{28}O_{22} + 4H_2O = 4C_7H_6O_5 + C_6H_{12}O_6$. Digallic acid is the first anhydride of gallic acid—$C_{14}H_{10}O_9 + H_2O = 2C_7H_6O_5$. Gallic acid is a *phenol acid*, or combination of these two classes of organic compounds, its formula being $C_6H_2(OH)_3.COOH$. It may be termed, therefore, a *trioxybenzoic acid*. It is monobasic.

Properties. Gallic acid is in delicate, silky, acicular crystals, which, as ordinarily found in the shops, are slightly brownish, but when quite pure are colorless. It is inodorous, and of a sourish, astringent taste and an acid reaction. "Soluble, at 15° C. (59° F.), in 100 parts of water, and in 5 parts of alcohol; in 3 parts of boiling water, and in 1 part of boiling alcohol. Also soluble in 40 parts of ether, and in 12 parts of glycerin." *U. S.* It is even less soluble in chloroform, benzol, and benzin. Mr. Thomas Weaver, of Philadelphia, has found that it is soluble in glycerin in the proportion of 40 grains to the ounce, and that the solution may be diluted to any extent with water without affecting its transparency. (*A. J. P.*, xxix. 82.) It produces a deep bluish-black color with solutions of ferric salts, which disappears when the solution is heated; a result which Dr. Mahla has shown to depend on the conversion of the gallic into *pyrogallic* or *metagallic acid*, by the loss of the constituents of carbonic acid and water. (*Am. Journ. of Sci. and Arts*, Nov. 1859.) It does not precipitate gelatin, or a solution of ferrous sulphate. "When heated at 100° C. (212° F.), the Acid loses its water of crystallization (nearly 9·6 per cent.). At about 222° C. (431·6° F.) it begins to melt, and at a higher temperature it is gradually decomposed. At a low red heat it is consumed without leaving a residue." *U. S.* It should leave no residue when burned, and be entirely dissipated when thrown on red-hot iron. On exposure to the air, its solution undergoes spontaneous decomposition; but it is said that by the addition of a drop of oil of cloves it may be kept for a long time without change, the absence of tannin and microscopic fungi being proved. "Gallic Acid neither colors nor precipitates pure ferrous salts, but forms a bluish-black precipitate with ferric salts. On adding to a cold, saturated, aqueous solution of Gallic Acid some calcium hydrate test-solution, a bluish-white precipitate will form, where the test-solution is temporarily in excess, and will disappear on shaking. When the test-solution has been added in excess, the precipitate no longer dissolves, and the liquid acquires a tint which is blue by reflected and green by transmitted light, and becomes pink on the addition of a large excess of calcium hydrate test-solution (distinction from *tannic acid*). An aqueous solution of the Acid should not precipitate alkaloids, gelatin, albumen, or starch test-solution (difference from and absence of *tannic acid*)." *U. S.* "It yields a bluish-black precipitate with *test-solution of ferric chloride*. The crystalline Acid loses 9·5 per cent. of its weight when dried at 212° F. (100° C.). It should yield no characteristic reaction with the tests for sulphates. Its aqueous solution is not precipitated by *solutions of isinglass, albumen*, alkaloids, or *tartarated antimony* (absence of tannic acid). It leaves no residue when burned with free access of air (freedom from mineral matter)." *Br.* By the action of arsenic it is converted almost entirely into tannic acid without the production of arsenous acid. (Schiff, *Chem. News*, xxix. 73.) Young's test, potassium cyanide, gives a reddish color with gallic acid and none with tannic acid. A mixture of ammonium chloride and ammonia produces a red coloration but no precipitate in gallic acid solution, while in tannic acid solution it produces a whitish precipitate rapidly turning reddish-brown. (*A. J. P.*, April 1889.) A test proposed by Flückiger consists in adding to the solution of gallic acid a dilute (1 to 100) solution of pure ferrous sulphate. To the colorless solution a little sodium acetate is to be added, when a deep violet color will appear, due to the formation of ferrous gallate.

The Pharmacopœia test is: "If 5 C.c. of a cold saturated aqueous solution of the Acid be treated, in a watch-glass, with 6 drops of sodium hydrate test-solution, the liquid will gradually acquire a deep green color, which is changed to reddish or brownish-red by acids." Heated to 216° C. (420° F.), gallic acid gives off carbon dioxide, and is changed into *pyrogallic acid.*

Medical Properties. Gallic acid is astringent, but less powerfully so than tannic acid. As it does not coagulate albumen, it is readily absorbed when ingested, and is rapidly eliminated by the kidneys. Its presence in the urine is under these circumstances very readily demonstrated by the addition of a soluble ferric salt. Owing to its being more readily transported by the blood, it is more effective than tannic acid in all cases of hemorrhage (*hæmoptysis, hæmaturia*, etc.) in which the bleeding vessels must be reached through the route of the circulation. But in hemorrhage from the alimentary mucous membrane, or from any other part with which tannic acid can be brought into direct contact, the latter astringent is by far the more effectual. Tannic acid is also much more efficient in *anginose or other relaxations* in which a decided astringent action is desired and in which a direct application can be made. Gallic acid has been employed with advantage in *pyrosis*, and in the *night-sweats* of *phthisis* or *exhaustion*. In *albuminuria*, when there is a very large amount of albumen excreted, gallic acid may be employed with service to diminish the flow, and the drug has even been used in acute *Bright's disease* following *scarlatina*, with asserted great advantage. (*N. R.*, Oct. 1875.) It is said not to constipate the bowels. The dose is from five to fifteen grains (0·32–0·97 Gm.) three or four times a day, and may be given in the form of pill or powder. *Ointment of Gallic Acid*, ten parts of the acid to ninety of benzoinated lard, was official in the Pharmacopœia of 1880.

ACIDUM HYDROBROMICUM DILUTUM. U. S., Br. Diluted Hydrobromic Acid.

(ĂC'I-DŬM HĪ-DRŌ-BRŌ'MĬ-CŬM DĬ-LŪ'TŬM.)

"A liquid composed of 10 per cent., by weight, of absolute Hydrobromic Acid [HBr = 80·76], and 90 per cent. of Water. Diluted Hydrobromic Acid should be kept in glass-stoppered bottles, protected from light." *U. S.* "An aqueous solution containing 10 per cent. by weight of hydrogen bromide, HBr. It may be obtained by the distillation of potassium bromide with concentrated phosphoric acid." *Br.*

Acidum Bromhydricum Dilutum, Acidum Bromohydricum; Acide hydrobromique, *Fr.*; Hydrobromsäure, Bromwasserstoffsäure, *G.*

The U. S and Br. Pharmacopœias do not give processes for this acid. Both acids are identical in strength; the former British process is as follows: "Bromine, 1 fluidounce [Imp. meas.]; Distilled Water, Sulphuretted Hydrogen, of each a sufficiency. Place the bromine in a glass cylinder and pour over it 15 ounces [Imp. meas.] of the water. Pass a current of sulphuretted hydrogen gas into the bromine until the red color of the aqueous liquid has disappeared. Filter the fluid and distil the filtrate. Reject the distillate until it is free from odor of sulphuretted compounds, and then collect it until sulphuric acid begins to distil. Dilute the distilled acid with water until it has a specific gravity at 60° F. (15·5° C.) of 1.077. Preserve in glass-stoppered bottles. From the rejected distillate more hydrobromic acid may be obtained by redistillation." *

* The following process is based upon that of Dr. E. R. Squibb:

Take of Potassium Bromide and Sulphuric Acid, each, one hundred and fifty parts, Distilled Water, a sufficient quantity. Add the Sulphuric Acid to twenty-five parts of Distilled Water, and cool the mixture. Then dissolve the Potassium Bromide in one hundred and fifty parts of water by the aid of heat, supplying the loss of water by evaporation during the heating. Carefully pour the diluted Sulphuric Acid into the hot solution with constant stirring, and set the mixture aside for twenty-four hours, in order that the Potassium Sulphate may crystallize. Pour off the liquid into a retort, break up the crystalline mass, transfer it to a funnel, and having drained the crystals, drop slowly upon them fifty parts of cold Distilled Water so as to wash out the acid liquid. Add this liquid to that in the retort, and distil nearly to dryness at a moderate heat. If red fumes of bromine are given off during any stage of the distillation, change the receiver as soon as such fumes cease to appear. Finally determine in the distillate the amount of actual Hydrobromic Acid (16·2 Gms. should require 20 C.c. of the volumetric solution of soda), and add to the remaining weighed distillate such an amount of cold Distilled Water as shall cause the finished acid to contain 10 per cent. of actual hydrobromic acid. If the bromide used contains bromate, the distillate will probably be tinged with the red color of bromine; should such contamination be produced, the acid may be rendered fit for use by carefully adding solution of sodium sulphite until the acid is deprived of color, and then rectifying it by distillation.

This process for making solution of hydrobromic acid does not differ essentially from that of Dr. E. R. Squibb (*A. J. P.*, 1878, p. 116), except in the improvement of the rather smaller proportion of sulphuric acid used, and in the fact of the difference in strength of the two hydrobromic acids, Dr. Squibb's being 34 per cent., the above 10 per cent. The advantages possessed by both methods over those frequently used are greater purity of product and more definite strength.

The most convenient process is undoubtedly that of Dr. Dewitt C. Wade (*Peninsular Medical Journal*, Feb. 1875), modelled after Buchanan's method of making hydriodic acid, which directs that 120 grains of potassium bromide be dissolved in one fluidounce of water, and 153 grains of tartaric acid be added to the solution; acid potassium tartrate is produced, the greater part of which crystallizes out on standing 12 hours at a low temperature, and a solution of hydrobromic acid is formed, sp. gr. 1·228, containing about 80 grains real hydrobromic acid to the fluidounce, equivalent to nearly 15 per cent. Fothergill's acid, although based upon Wade's formula, is weaker, the quantity of potassium bromide being 81¼ grains and that of tartaric acid 99 grains to the fluidounce, the manipulation being the same; each fluidounce of Fothergill's acid contains about 55 grains real hydrobromic acid, or about 10 per cent. Diluted hydrobromic acid made in this way is open to the objection of containing cream of tartar, and probably some undecomposed potassium bromide in solution, and thus is not strictly pure. To lessen this, Charles Rice proposes the addition of a double quantity of alcohol to facilitate the precipitation, recovering the alcohol by distillation subsequently. (*N. R.*, 1877, p. 107.) Other processes have been suggested for preparing hydrobromic acid. Edward Goebel (*N. R.*, Sept. 1880) proposes a method based on Glover's process, which is to decompose 148 grains barium bromide, dissolved in half an ounce of water, with 50·6 grains sulphuric acid, diluted with two drachms of distilled water; the precipitated barium sulphate is washed with distilled water until the filtrate weighs 810 grains to make the 10-per-cent. acid solution. Winckler proposes a plan for making hydriodic acid, which has been adapted by Charles Rice to making hydrobromic acid. (See *N. R.*, Jan. 1880.) Bromine is dissolved in carbon disulphide and hydrogen sulphide passed through the solution. The processes of Balard, Millon, and Loewig are commented upon by John M. Maisch (*Proc. A. P. A.*, 1860), who proposes some useful modifications. Prof. Markoe (*Ibid.*, 1875, p. 686) recommends an economical process, which, however, must be followed with care, and is better adapted for making the acid on a large scale. He pours a pint of water into a gallon stoneware jar, and then adds one pound or more of phosphorus, distributing it over the bottom; ice is now added until the jar is half full, a gallon glass funnel is inserted in the throat of the jar, and a funnel tube adjusted, so that the end will be a short distance above the surface of the phosphorus; the funnel is about one-third filled with broken ice, and the jar placed in a larger vessel, and broken ice packed between. Three or four pounds of bromine after being chilled are *slowly* added, in order that the fumes of hydrobromic acid and bromine that may arise may be fully condensed by the ice in the funnel, and an accumulation of bromine avoided, which might produce an explosion from too sudden reaction. The excess of phosphorus is removed after all the bromine has been added, the liquid distilled, hydrobromic acid condensed, and the strength adjusted, whilst to the residue in the retort water may be added to make diluted phosphoric acid. For other processes see Wène (*Comptes-Rend.*, 1849), Bruylants (*Journ. de Pharm. d'Anvers*, 1879, p. 343, and *A. J. P.*, Jan., 1880), Hager (*Handbuch d. Pharm. Praxis*, i. 628), Grüning (*N. R.*, 1883, p. 240), Stas (*Zeitsch. f. Anal. Chem.*, 1886, p. 213).

Properties. Diluted hydrobromic acid is a colorless, transparent liquid, entirely vaporized by heat, inodorous, strongly acid to the taste, sp. gr. 1·077* (U. S. and Br.) at 15° C. (59° F.), containing 10 per cent. absolute hydrobromic acid. "Miscible, in all proportions, with water and alcohol. By heat it is completely volatilized. On distilling it, water and weak acid first pass over. When the temperature of 126° C. (258·8° F.) is reached, an acid of 47·8 per cent. remains, which may be distilled unchanged. With litmus paper it shows a strongly acid reaction." *U. S.* Although of a pungent and irritating odor, and fuming when in contact with the atmosphere when concentrated, in its diluted state it is odorless. On adding chlorine or nitric acid to diluted hydrobromic acid, there is liberated bromine, which is soluble in chloroform or disulphide of carbon, imparting to these liquids a yellow color.

Tests. "Silver nitrate test-solution causes a yellowish-white precipitate, somewhat soluble in hydrobromic acid, insoluble in diluted nitric acid, very slightly soluble in ammonia water, but more soluble in stronger ammonia water. Copper sulphate test-solution produces a deep-red color upon addition of sulphuric acid. On being kept for some time, the Acid should not become colored. Barium chloride test-solution should not produce a turbidity or precipitate (absence of *sulphuric acid*). If 1 C.c. of the Acid be mixed with 1 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), and a small piece of pure tin-foil added, no brown coloration should appear within half an hour (limit of *arsenic*). To

* Dr. E. R. Squibb takes exception to the sp. gr. 1·077 given for the official acid, and states that Biel's table is not accurate, the proper sp. gr. for a 10-per-cent. acid at 15° C. (59° F.) being 1·0698. (*Ephemeris*, vol. i. p. 366.)

neutralize 8·08 Gm. of Diluted Hydrobromic Acid should require 10 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.* "4 grammes should require for neutralization 5 (more exactly 4 98) cubic centimetres of the *volumetric solution of sodium hydroxide*, or, for complete precipitation, 50 (more exactly 49·8) cubic centimetres of the *volumetric solution of silver nitrate.* It should yield no characteristic reaction with the tests for arsenium, barium, chlorides, phosphates, sulphates, or sulphites. It should yield no residue on evaporation to dryness." *Br.* Concentrated hydrobromic acid has been furnished by manufacturing chemists containing from 20 to 50 per cent. of absolute hydrobromic acid; Charles T. Tyrer states that the stronger acids are prone to show discoloration in a few days after being made, but that even the highly colored acids, when diluted to the official strength, become colorless; the concentrated acid attacks glass rapidly and the silica is not thrown out on dilution; he recommends acid of the sp. gr. 1·250 as having the most suitable limit of concentration for pharmaceutical purposes. (*Yearbook of Pharmacy*, 1896, 296.).

The following table by Biel will be found useful in showing from the specific gravities of solutions the percentage of absolute hydrobromic acid:

Biel's table of Percentage and Specific Gravity of Hydrobromic Acid.

Medical Properties and Uses. Dilute hydrobromic acid is very nearly identical with potassium bromide in its action, but is too irritant to the stomach to be used freely in *epilepsy* and other serious affections. In an experimental study made by Dr. Reichert, of the University of Pennsylvania, it was found to act upon animals precisely as do the bromides in general. It has been especially commended in *tinnitus aurium.* Two fluidrachms contain 12 grains of bromine, equivalent in this to 18 grains of potassium bromide, and may be given at once, well diluted with syrup. The addition of a trace of spirit of lemon to the syrup renders the resemblance of this dose to lemonade a very close one.

ACIDUM HYDROCHLORICUM. U. S., Br. Hydrochloric Acid.

[Muriatic Acid.]

(ĂQ'I-DŬM HĪ-DRQ-ȻHLŌ'RI-CŬM.)

"A liquid composed of 31·9 per cent., by weight, of absolute Hydrochloric Acid [HCl = 36·37], and 68·1 per cent. of water. Hydrochloric Acid should be kept in dark amber-colored, glass-stoppered bottles." *U. S.* "A liquid containing 31·79 per cent. by weight of hydrogen chloride, HCl, and 68·21 per cent. of water. Obtained by dissolving in water the gas produced by the interaction of sulphuric acid and sodium chloride." *Br.*

Acidum Muriaticum, *Pharm.* 1870; Acidum Hydrochloratum, s. Chlorhydricum; Spirit of Sea-Salt, Marine Acid, Muriatic Acid, Chlorhydric Acid; Acide hydrochlorique, Acide chlorhydrique, ou muriatique, *Fr.;* Salzsäure, Chlorwasserstoffsäure, *G.;* Acido muriatico, *It., Sp.*

The hydrochloric acid of pharmacy and the arts is a solution of hydrochloric acid *gas* in water. The former British Pharmacopœia gives the following process for preparing it:

"Take of Chloride of Sodium, dried, *forty-eight ounces* [avoirdupois]; Sulphuric Acid *forty-four fluidounces;* Water *thirty-six fluidounces;* Distilled Water *fifty fluidounces.* Pour the Sulphuric Acid slowly into thirty-two [fluid]ounces of the Water, and when the mixture has cooled, add it to the Chloride of Sodium previously introduced into a flask having the capacity

of at least one gallon [Imp. meas.]. Connect the flask by corks and a bent glass tube with a three-necked wash-bottle, furnished with a safety tube, and containing the remaining four [fluid]ounces of the Water; then, applying heat to the flask, conduct the disengaged gas through the wash-bottle, into a second bottle containing the Distilled Water, by means of a bent tube dipping about half an inch below the surface; and let the process be continued until the product measures sixty-six [fluid]ounces, or the liquid has acquired a sp. gr. of 1·16. The bottle containing the distilled water must be kept cool during the whole operation." *Br.*

Preparation. Hydrochloric acid is obtained mainly by the action of sulphuric acid on sodium chloride or common salt. In England it is produced in enormous quantities during the decomposition of common salt for the purpose of making sodium sulphate, from which soda-ash and sodium carbonate are afterwards manufactured in immense quantities. The decomposition of the sea-salt is performed in semi-cylindrical vessels, the curved part, next the fire, being made of iron, and the upper or flat surface, of stone. The acid gas is conveyed by a pipe to a double-necked stoneware receiver, half filled with water, and connected with a row of similar receivers, likewise containing water. As carried out on a larger scale, the decomposition of the salt takes place in hemispherical iron pans, 9 feet in diameter, covered by a brick-work dome; upon the mass of salt the requisite quantity of sulphuric acid is allowed to run from a leaden cistern placed above the decomposing-pan. Torrents of hydrochloric acid gas are evolved, which collect in the space between the pan and the brick-work dome, whence they pass by a brick-work or earthenware flue into upright towers or condensers. These towers are filled with bricks or coke, down which a small stream of water is allowed to trickle. The gas, passing upward, meets the water, and is dissolved by it; and as the acid liquor approaches the bottom of the tower, it becomes more and more nearly saturated with the gas.

Hydrochloric acid is also made on a commercial scale from magnesium chloride, which is such an abundant waste product at the rock-salt mines of Stassfurt. The process used is that of Weldon as developed by Pechiney, of Salindres, in France.

The acid, when required to be pure, is generally prepared by saturating distilled water with the gas in a Woulfe's apparatus. A quantity of pure fused common salt is introduced into a retort or matrass, placed on a sand-bath. The vessel is then furnished with an S-tube, and connected with a series of bottles, each two-thirds full of water. A quantity of sulphuric acid is then gradually added, equal in weight to the common salt employed, and diluted with one-third of its weight of water. The materials ought not to occupy more than half the body of the retort. When the extrication of the gas slackens, heat is applied, and gradually increased until the water in the bottles refuses to absorb any more, or until no more gas is found to come over. As soon as the process is completed, boiling water should be added to the contents of the retort or matrass, in order to facilitate the removal of the residue. During the progress of the saturation, the water in the several bottles increases in temperature, which lessens its power of absorption. It is, therefore, expedient, in order to obtain a strong acid, to keep the bottles cool by means of water or ice. The connecting tubes need not plunge deeply into the acid.

The process of the former British Pharmacopœia is substantially the same as the one here described, with the exception of the proportion of the acid and salt employed. In the process for hydrochloric acid, theory calls for a little less than 82 parts of liquid sulphuric acid to 100 of common salt. A moderate excess of the former may be useful to insure the complete decomposition of the salt; but the quantity of acid directed in the British process is sufficient to decompose twice the quantity of common salt taken. The intention obviously is to use enough of the acid to form the acid sulphate instead of the neutral sodium sulphate; the former being more soluble and readily removed from the retort, and the reaction requiring less heat for its completion than when one mol. of sulphuric acid is taken to two mols. of salt. The reaction for its formation is $NaCl + H_2SO_4 = HCl + HNaSO_4$. If only half the amount of sulphuric acid be used, the reaction is $(NaCl)_2 + H_2SO_4 = (HCl)_2 + Na_2SO_4$. In the first of these reactions (that of the British Pharmacopœia process), as only one mol. of salt is taken, it is obvious that there is not enough sodium furnished to neutralize the sulphuric acid completely and make the normal sulphate Na_2SO_4, so the result is the acid sulphate (bisulphate) $HNaSO_4$. On the other hand, in the second reaction, the two mols. of salt furnish just the sodium necessary to neutralize the one mol. of sulphuric acid and make the neutral sulphate Na_2SO_4.

As hydrochloric acid, prepared in the ordinary mode, often contains arsenic, so as to obscure its indications when employed in testing for that poison, it is of interest to the practical toxicologist to know that it may be obtained free from that impurity by distilling sodium or potassium chloride with oxalic acid in equivalent proportions.

The following method of freeing hydrochloric acid from arsenous acid is recommended by M. Engel as easy and entirely efficacious. It is founded on the fact that arsenous acid is held in solution by hypophosphorous acid. Into a litre (about 2 pints) of arsenical hydrochloric acid introduce 4 to 5 grammes (about 60 or 70 grains) of potassium hypophosphite, dissolved in a little water. At the end of an hour or two, the liquid becomes yellow and then brown; and a precipitate soon forms, more or less copious according to the amount of impurity. After the liquid becomes clear, which usually happens in 45 minutes, decant the hydrochloric acid and distil it. The acid thus obtained is entirely free from arsenic. This process should be conducted in a place where the direct rays of the sun may fall on the vessels; or, where this is impossible, the vessels should be subjected, by means of a water-bath, from 4 to 6 hours, to a heat little short of the boiling point of the acid. (*Journ. de Pharm.*, 1873, p. 10.) Traces of arsenic may also be removed by adding solution of stannous chloride, and after the precipitate of impure arsenic has settled, the clear liquid is re-distilled. (Bettendorff, *Zeit. für Chem.* [2], 5, p. 492.)

Properties of the Pure Acid. Hydrochloric acid, when pure, is a transparent colorless liquid, of a suffocating odor and corrosive taste. Exposed to the air it emits white fumes, owing to the escape of the acid gas and its union with the moisture of the atmosphere. When concentrated, it blackens organic substances, like sulphuric acid. Its sp. gr. varies with its strength. When as highly concentrated as possible, its density is 1·21. The *U. S. acid*, as well as that of the present British Pharmacopœia, has the sp. gr. 1·16. (*U. S.* 1·163.) "3·64 Gm. should require for complete neutralization 31·9 C.c. of potassium hydrate normal volumetric solution." *U. S.* When exposed to heat, it continues to give off hydrochloric acid gas, with the appearance of ebullition, until its sp. gr. falls to 1·094, when it properly boils, and may be distilled unchanged, or entirely volatilized.

Hydrochloric acid is characterized by forming, on the addition of silver nitrate, a white precipitate (silver chloride), insoluble in nitric acid, but readily soluble in ammonia. It is incompatible with alkalies and most earths, with oxides and their carbonates, and with potassium sulphide, potassium tartrate, tartar emetic, iron and potassium tartrates, silver nitrate, and solution of lead subacetate.

"On heating it, at first a stronger acid passes off, until, at 110° C. (230° F.), a liquid containing 20·18 per cent. of the absolute acid remains (specific gravity about 1·102 at 15° C.), which distils unchanged, leaving no residue, if the Acid was perfectly pure." *U. S.*

As it is desirable to know, on many occasions, in chemical and pharmaceutical operations, the quantity of absolute acid contained in samples of acid of different densities, we subjoin the table of Lunge and Marchlewski, with additions from the U. S. P. 1890:

Table of Percentage and Specific Gravity of Hydrochloric Acid.

LUNGE AND MARCHLEWSKI.

1·071	14·17	1·141	27·66		

It is to be understood that the values given in this table refer only to chemically pure acids. The percentage of real acid in the commercial acids, particularly when they are concentrated, is always less than that given in these tables. [Lunge.]

Impurities. This acid, when pure, will evaporate without residue in a platinum spoon. On heating it with black manganese oxide an abundance of chlorine gas is given off. If sulphuric acid be present, a solution of barium chloride will cause a precipitate of barium sulphate in the acid, previously diluted with distilled water. Iron may be detected by saturating the diluted acid with sodium carbonate, and then adding potassium ferrocyanide, which will strike a blue color if that metal be present, or by the simple addition of potassium sulphocyanate, when a blood-red coloration is produced. The absence of arsenic may be inferred if it does not tarnish bright copper foil when boiled with it. "If 10 C.c. of the Acid be evaporated from a platinum or porcelain capsule, not more than a bare trace of residue should be left (limit of *non-volatile impurities*). A few drops of chloroform, added to 1 C.c. of Hydrochloric Acid diluted with 2 C.c. of water, should not become colored, either at once, or after the addition of a few drops of freshly prepared chlorine water, or of a granule of potassium chlorate (absence of *iodine* or *bromine*). If 1 C.c. of the acid be diluted with 5 C.c. of water and 0·5 C.c. of zinc-iodide-starch test-solution added, no blue color should appear (absence of *chlorine* or *bromine*). On adding 1 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), together with a small piece of pure tin-foil, to 1 C.c. of the Acid, no coloration should occur within one hour (limit of *arsenic*). If 1 C.c. of the Acid be diluted with 5 C.c. of water, and a few drops of barium chloride test-solution added, no precipitate or turbidity should appear within one hour (absence of *sulphuric acid*), nor should the addition to this mixture of a few drops of iodine decinormal volumetric solution produce any turbidity (absence of *sulphurous acid*). When a few C.c. of freshly saturated hydrogen sulphide test-solution are poured carefully on top of an equal volume of Hydrochloric Acid, no color should develop at the zone of contact (absence of *thallium*, *arsenic*, *lead*, etc.). If 1 C.c. of Hydrochloric Acid be slightly supersaturated with ammonia water, and 1 C.c. of ammonium sulphide test-solution added, neither a color nor a turbidity should appear (absence of *iron*, *aluminum*, etc.)." *U. S.* "Each gramme, diluted with *water*, should require for neutralization 8·7 cubic centimetres of the *volumetric solution of sodium hydroxide*, and 0·1 gramme should require, for complete precipitation, 8·7 cubic centimetres of the *volumetric solution of silver nitrate*. It leaves no residue on evaporation, and when diluted with *water* should yield no characteristic reaction with the tests for arsenium, lead, copper, iron, aluminium, bromides, iodides, sulphates, or sulphites. Diluted with much *water* and *solution of potassium iodide* added, no blue color is produced on the addition of *mucilage of starch* (absence of free chlorine)." *Br.* Ammonia in excess shows the absence of iron, if it produces no precipitate.

If another portion of the diluted acid be treated with test zinc, the evolved gas should not blacken paper wet with silver nitrate test-solution (arsenous or sulphurous acid). Free chlorine or nitric acid may be discovered by its having the power to dissolve gold-leaf. Any minute portion of the leaf which may be dissolved is detected by adding a solution of stannous chloride, which will give rise to a purplish tint. The free chlorine is derived from the reaction of nitric or nitrous acid on a small portion of the hydrochloric acid, which is thus deprived of its hydrogen. Hence it is that, when free chlorine is present, nitrous acid or some other oxide of nitrogen is also present as an impurity. The nitric and nitrous acids are derived from nitrates in the common salt and from nitrous acid in the commercial sulphuric acid employed in the preparation of the hydrochloric acid.

Hydrochloric Acid of Commerce. This acid has the general properties of the pure aqueous acid. It has a yellowish color, owing to the presence of iron sesquichloride, or of a minute proportion of organic matter, such as cork, wood, etc. It usually contains sulphuric acid, and sometimes free chlorine and nitrous acid. But the most injurious impurity, to those who consume it in the arts, is sulphurous acid. T. H. Savory analyzed three samples of commercial hydrochloric acid, each having a sp. gr. of between 1·16 and 1·17, and found them to contain from 7 to nearly 11 per cent. of sulphurous acid. To detect this acid, M. Girardin has proposed a very delicate test, namely, stannous chloride. The mode of using the test is to take about half an ounce of the acid to be tested, and to add to it two or three drachms of the stannous chloride. The mixture having been stirred two or three times, as much of distilled water as of the stannous salt is to be added. If sulphurous acid be present, the hydrochloric acid becomes turbid and yellow immediately upon the addition of the stannous chloride; and upon the subsequent addition of the water a slight evolution of hydrogen sulphide takes place, perceptible to the smell, and the liquid assumes a brownish hue, depositing a powder of the same color. The manner in which the test acts is as follows. By a transfer of chlorine, the test is converted into stannic chloride and metallic tin, the latter of which, by reacting with

the sulphurous acid, gives rise to a precipitate of stannic and stannous sulphides. In case the sulphurous acid forms but one-half of one per cent. of the commercial acid, the precipitate may not be perceptible. Under these circumstances, a solution of copper sulphate must be added to the liquid previously warmed, when a brown precipitate of copper sulphide will be immediately formed. (*Heintz.*) Or, if a weak solution of iodine be decolorized by the hydrochloric acid, sulphurous or arsenous acid may be suspected. M. Lembert has proposed the following, which he considers as a more delicate test of sulphurous acid. Saturate the suspected hydrochloric acid with potassium carbonate, and add successively a little weak solution of starch, one or two drops of solution of potassium iodate, and sulphuric acid, drop by drop. Sulphurous acid, if present, will be set free with iodic acid, and these, by reacting on each other, will develop iodine, which will cause a blue color with the starch. Or the addition of pure zinc will liberate nascent hydrogen, which will cause the evolution of hydrogen sulphide gas detected with lead acetate paper.

Another impurity occasionally present in the commercial acid, as shown by Dupasquier, is arsenic. (See U. S. P. tests above.) The immediate source of this impurity is the sulphuric acid used to prepare the hydrochloric acid. The sulphuric acid derives the arsenic from the sulphur used in its manufacture, and this last from pyrites containing a little of the poisonous metal. The arsenic, when present, is in the form of a terchloride, and, from its volatility in this state of combination, is transferred to the hydrochloric acid, distilled from the commercial acid. This impurity is separated by diluting the acid with an equal volume of water, and passing through it hydrogen sulphide, which thus throws down the arsenic as a tersulphide. According to Wittstein, hydrochloric acid is freed from arsenic by mercury, according to Reinsch, by copper, and in either case it may be deprived of metallic impregnation by careful distillation. (*A. J. P.*, 1851, p. 408.) M. Auguste Houzeau asserts that to deprive commercial arseniferous hydrochloric acid of arsenic it is sufficient simply to boil it, in a flat-bottomed vessel, to two-thirds of its original volume; all the arsenic escaping in the form of the terchloride. (*Journ. de Pharm. et de Chim.*, 4e sér., i. 97.) Bettendorff separates arsenous and arsenic acids from hydrochloric acid, sufficiently concentrated, by precipitating with stannous chloride, and then distilling the acid: when it is so treated, it is perfectly free from arsenic. (*A. J. P.*, 1870, p. 219.) When leaden vessels are used in preparing hydrochloric acid, it is apt to contain lead chloride, which falls as a white precipitate on neutralizing the acid. The nature of the precipitate is verified by dissolving it in nitric acid and adding potassium iodide, when the yellow lead iodide will fall. (*Hainault.*) Prof. E. Scheffer proved the presence of lead in a sample used for making solution of iron perchloride. (*A. J. P.*, Nov. 1875.) Another instance was noted by F. Reppert. (*A. J. P.*, Dec. 1875.) This impurity, being fixed, may be separated by distilling the acid. A small proportion of thallium has been detected in commercial hydrochloric acid by Mr. Wm. Crookes, being derived from sulphuric acid, in the manufacture of which pyrites were employed. (*Chem. News*, 1863, p. 194.) Selenium has been found in French hydrochloric acid, causing it to have a characteristic bad odor.

Properties of Hydrochloric Acid Gas. Hydrochloric acid gas is a colorless elastic fluid, possessing a pungent odor, and the property of irritating the organs of respiration. It destroys life and extinguishes flame. It reddens litmus powerfully, and has the other properties of a strong acid. Its sp. gr. is 1·278 (Gay-Lussac and Biot). Subjected to a pressure of 40 atmospheres, at the temperature of 10° C. (50° F.), it is condensed into a transparent liquid, to which alone the name of *liquid hydrochloric acid* properly belongs. It is absorbed by water with the greatest avidity.

Composition. Hydrochloric acid gas consists of one atom of chlorine and one of hydrogen, or of one volume of chlorine and one of hydrogen, united without condensation.

Medical Properties. Hydrochloric acid is tonic, refrigerant, and antiseptic. It is exhibited, largely diluted with water, in *low fevers*, *phthisis*, some forms of *syphilis*, and to counteract *phosphatic deposits* in the urine. It is especially valuable in *gastro-intestinal indigestion* when there is no tendency to diarrhœa, and may often be added with advantage to liquid preparations of columbo, gentian, and cinchona. It is also frequently given in *dyspepsia* along with pepsin, to aid its solvent powers. The dose for internal exhibition is from five to ten minims (0·3–0·6 C.c.), well diluted. (See *Acidum Hydrochloricum Dilutum.*) It is a decided caustic when applied in concentrated form, although less powerful than nitric acid, and is frequently used to destroy small dermal growths.

Toxicological Properties. Hydrochloric acid, when swallowed, is highly irritating and corrosive, but less so than sulphuric or nitric acid. It produces hiccough, violent efforts to

vomit, and agonizing pain in the stomach. There is much thirst, with great restlessness, a dry and burning skin, and a small concentrated pulse. If the acid have been recently swallowed, white vapors of a pungent smell will be emitted from the mouth. The best antidote is magnesia, but soap or sufficiently dilute alkaline solutions are almost equally efficient. In the course of the treatment, bland and mucilaginous drinks must be freely given. When inflammation supervenes, it must be treated on general principles.

ACIDUM HYDROCHLORICUM DILUTUM. U. S., Br. Diluted Hydrochloric Acid. [Diluted Muriatic Acid.]

(ĂQ'I-DŬM HĬ-DRŌ-ĢHLŌ'RI-CŬM DI-LŪ'TŬM.)

"100 parts by weight should contain 10·58 parts of hydrogen chloride, HCl." *Br.*

Acidum Muriaticum Dilutum, *Pharm.* 1870; Acide chlorhydrique dilué, *Fr.;* Verdünnte Salzsäure, *G.*

"Hydrochloric Acid, *one hundred grammes* [or 3 ounces av., 230 grains]; Distilled Water, *two hundred and nineteen grammes* [or 7 ounces av., 317 grains], To make *three hundred and nineteen grammes* [or 11 ounces av., 110 grains]. Mix them. Keep the product in glass-stoppered bottles." *U. S.*

"Hydrochloric Acid, 6 *fl. ounces* (more exactly, 6·035, Imperial measure) or 3063 *grains*, or 301·8 cubic centimetres or 350·1 grammes; Distilled Water, a sufficient quantity. Introduce the Hydrochloric Acid into a glass flask, the capacity of which to a mark on the neck is *one pint* (Imp. meas.) or one thousand cubic centimetres; add Distilled Water until the mixture, at 60° F. (15·5° C.), after it has been shaken, measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The existing U. S. formula differs from that of 1870 in yielding a diluted hydrochloric acid, which contains about twelve per cent. more official acid than did the older preparation. The change was made in order that the diluted mineral acids might have a uniform strength (ten per cent. of absolute acid). It is important to bear this fact in mind in prescribing, although the difference is not sufficient to render the present strength dangerous. "Diluted Hydrochloric Acid contains 10 per cent. of absolute Hydrochloric Acid. Specific gravity, about 1·050 at 15° C. (59° F.). It does not fume in the air, and is without odor, but otherwise it corresponds in properties to Hydrochloric Acid (see *Acidum Hydrochloricum*), and should conform to the same reactions and tests. To neutralize 3·64 Gm. of Diluted Hydrochloric Acid should require 10 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.*

The British diluted acid is slightly stronger than the U. S. preparation. "Sp. gr. 1·052, containing 10·58 per cent. by weight of absolute acid. Each gramme should require for neutralization 2·9 cubic centimetres of the *volumetric solution of sodium hydroxide.* It should be free from the impurities mentioned under 'Acidum Hydrochloricum.'" *Br.* The extreme precision of both formulas, though no doubt useful when the diluted acid is used as a test, is unnecessary from the point of view of the practical physician.

For medical properties and uses, see *Acidum Hydrochloricum.* The dose of the diluted acid is from fifteen to thirty minims (0·92–1·85 C.c.), to be taken in water.

ACIDUM HYDROCYANICUM DILUTUM. U.S., Br. Diluted Hydrocyanic Acid. [Prussic Acid.]

(ĂQ'I-DŬM HĬ-DRŌ-CĬ-ĂN'I-CŬM DI-LŪ'TŬM.)

"A liquid composed of 2 per cent., by weight, of absolute Hydrocyanic Acid [HCN = 26·98], and 98 per cent. of water." *U. S.* "An aqueous solution containing 2 per cent. by weight of hydrogen cyanide, HCN. It may be prepared by the interaction of diluted sulphuric acid and potassium ferrocyanide. Diluted Hydrocyanic Acid should be stored in a dark place, in small stoppered bottles of amber-colored glass; the stoppers being tied over with impervious tissue and the bottles inverted." *Br.*

Cyanhydric Acid; Acidum Hydrocyanatum s. Borussicum; Acide cyanhydrique, ou hydrocyanique, *Fr.;* Cyanwasserstoff-Säure, Blausäure, *G.*

"Potassium Ferrocyanide, in coarse powder, *twenty grammes* [or 308 grains]; Sulphuric Acid, *eight cubic centimeters* [or 1 fluidrachm, 11 minims]; Water, *sixty-five cubic centimeters* [or 2 fluidounces, 95 minims]; Distilled Water, *a sufficient quantity.* Place the Potassium Ferrocyanide in a tubulated retort, and add to it *forty cubic centimeters* [1 fluidounce, 3 fluidrachms] of Water. Connect the neck of the retort (which is to be directed upward), by

means of a bent tube, with a well-cooled condenser, the delivery tube of which terminates in a receiver surrounded with ice-cold water, and containing *sixty-five cubic centimeters* [or 2 fluidounces, 95 minims] of Distilled Water. All the joints of the apparatus, except the neck of the receiver, having been made air-tight by means of well-fitting corks, pour into the retort, through the tubulure, the Sulphuric Acid, previously diluted with *twenty-five cubic centimeters* [6 fluidrachms, 45 minims] of Water. Gently mix the contents of the retort, and then heat it, in a sand-bath, so as to keep the liquid in brisk ebullition, until about one-half of its volume has passed over into the receiver. Detach the receiver, and assay a small portion of the contents by the method given below. Then add to the remainder so much Distilled Water as may be required to bring the product to the strength of *two per cent.*, by weight, of absolute Hydrocyanic Acid.

"*Diluted Hydrocyanic Acid* may also be prepared, extemporaneously, in the following manner: Silver Cyanide, *six grammes* [or 92·5 grains]; Hydrochloric Acid, *five cubic centimeters* [or 1 fluidrachm, 21 minims]; Distilled Water, *fifty-five cubic centimeters* [or 1 fluidounce, 6 fluidrachms, 52 minims]. Mix the Hydrochloric Acid with the Distilled Water, add the Silver Cyanide, and shake the whole together in a glass-stoppered bottle. When the precipitate has subsided, pour off the clear liquid. Diluted Hydrocyanic Acid should be kept in small, dark amber-colored, cork-stoppered vials, in a cool place." *U. S.*

The British Pharmacopœia does not give a detailed process for preparing this acid. It describes it as "A colorless liquid with a peculiar odor. Specific gravity 0·997. It only slightly reddens *litmus*. It yields, when neutralized, the reactions characteristic of cyanides." *Br.* It will be seen that both official acids recognize the same standard (2 per cent. of hydrogen cyanide).

When potassium ferrocyanide is decomposed by sulphuric acid, the residue in the retort is potassium sulphate, mixed with an insoluble compound of iron cyanide and potassium cyanide (*Everitt's Salt*). The reaction is expressed by the following equation:

$$2(K_4FeC_6N_6) + 3H_2SO_4 = 3K_2SO_4 + 2(KFeC_3N_3) + 6HCN.$$

Half of the cyanogen present in the potassium ferrocyanide goes to form the hydrocyanic acid, while the other half remains in the white residue. Everitt's salt, so named from its discoverer, is a yellowish-white powder. Like potassium ferrocyanide, it is a double salt (iron and potassium cyanide), but of different molecular ratio. As it appears in practice, it is apt to be greenish, owing probably to the presence of a little Prussian blue.

In the U. S. process for obtaining hydrocyanic acid extemporaneously, the reacting materials are single molecules respectively of silver cyanide and hydrochloric acid. These, by double decomposition, generate hydrocyanic acid, which dissolves in the water, and silver chloride, which subsides, and from which the acid is poured off when clear. (See *Argenti Cyanidum.*) The extemporaneous process is useful to country practitioners, because the acid will not generally keep. A portion of hydrocyanic acid, if purchased by a practitioner, may spoil on his hands before he has occasion to use it; but if he supply himself with silver cyanide, he may readily at any moment prepare a small portion of the acid, by following the directions of the formula. On the other hand, it is questionable whether all of the silver cyanide will be decomposed, except under much more careful treatment than the process is likely to receive.

The change which was made in the process of the Pharmacopœia of 1880, in the substitution of diluted alcohol for the distilled water formerly used as the solvent for the hydrocyanic acid, was in accordance with the views of Gault and others, who asserted that greater stability was thus secured. It has not proved of sufficient value to retain in the U. S. Pharmacopœia (1890), and the use of diluted alcohol has been abandoned. (See F. T. Drake, *Proceedings A. P. A.* 1891, p. 147.)

Another process for obtaining medicinal hydrocyanic acid, proposed by Dr. Clark, and adopted by Mr. Laming, is by the reaction of tartaric acid on potassium cyanide in solution. Laming's formula has been modified as follows. Potassium cyanide, pure, 65 parts; tartaric acid, 150 parts; alcohol, 675 parts; water sufficient to make 1538 parts. Mix the potassium cyanide and tartaric acid with 500 parts of water in a well-stoppered bottle, or dissolve each separately in 250 parts of water, and mix the solutions; then add the alcohol and sufficient water to make 1538 parts. After the acid potassium tartrate has subsided as a heavy crystalline powder, the clear supernatant liquid is decanted.

The yield of official acid is 1350 parts, but the generated cream of tartar weighs 188 parts, thus making the 1538 parts as above directed. The solution contains mere traces of the acid tartrate. (*A. J. P.*, 1883, p. 559, from *Fownes's Chemistry.*)

Great care must be observed in using this process to procure pure potassium cyanide, the commercial article usually being adulterated.

Recent investigations show that potassium ferrocyanide is decomposable not only by the weakest acids but also by numerous non-acid organic substances, hydrocyanic acid being liberated. The dilute mineral acids, containing even less than 0.1 per cent., formic, acetic, butyric, lactic, tartaric, benzoic acids, even carbonic acid and hydrogen sulphide, phenols, peptones, casein, etc., will decompose potassium ferrocyanide more or less quickly at temperatures below 100° C., liberating a portion of the hydrocyanic acid. (*A. J. P.*, 1893, p. 283.)

The processes thus far given are intended to furnish a *dilute* hydrocyanic acid for medicinal purposes. The methods of obtaining the *anhydrous* acid are different. Vauquelin's process for the anhydrous acid is to pass a current of hydrogen sulphide gas over mercury cyanide contained in a glass tube, connected with a receiver kept cold by a freezing mixture of ice and salt. The first third only of the tube is filled with cyanide; the remaining two-thirds being occupied, half with lead carbonate, and half with calcium chloride; the carbonate being intended to detain the hydrogen sulphide gas, the chloride to separate water.

The process of Wöhler for the anhydrous acid is the following. The potassium cyanide selected is a black cyanide, formed by fusing together, in a covered crucible, 8 parts of dry ferrocyanide, 3 of ignited cream of tartar, and 1 of charcoal in fine powder. The cyanide, while still warm, is exhausted by 6 parts of water; and the clear solution, placed in a retort, is decomposed by cold diluted sulphuric acid, gradually added. The hydrocyanic acid is condensed first in a U-tube containing calcium chloride and surrounded with ice-cold water, and afterwards in a small bottle, connected with the U-tube by a narrow tube, and immersed up to the neck in a mixture of ice and salt. After the acid has been condensed and dehydrated in the U-tube, the cold water surrounding it is withdrawn by a siphon, and replaced by water at a temperature between 29·4° and 32·2° C. (85°–90° F.), whereby the anhydrous acid is made to distil over into the small bottle.

M. Berthelot has made hydrocyanic acid synthetically. He first prepares, by a direct synthesis of its elements, *acetylene* (C_2H_2). He then mixes vapors of acetylene with pure nitrogen, passes a series of electric discharges from a Ruhmkorff coil through the mixture, and, when the odor of prussic acid is perceptible, agitates with a solution of potassa to get the fixed cyanide. It has also been made by heating chloroform with ammonia and caustic potash solution. (Hofmann, *Ann.*, 144, 116.)

Properties of the Medicinal Acid. Diluted hydrocyanic acid, of the proper medicinal strength, is a transparent, colorless, volatile liquid, possessing a smell resembling that of peach kernels, and a taste at first cooling and afterwards somewhat irritating. As it is very poisonous, great care should be taken in tasting it. "If to 1 C.c. of the Acid, rendered alkaline by potassium hydrate test-solution, a few drops, each, of ferrous sulphate test-solution and ferric chloride test-solution be added, and the mixture then acidulated with hydrochloric acid, a blue precipitate will be formed." *U. S.* It imparts a slight and evanescent red color to litmus. If it reddens litmus strongly and permanently, some acid impurity is present. It loses strength rapidly in open vessels. It is not reddened by potassium and mercury iodo-cyanide. The non-action of this test shows the absence of contaminating acids, which, if present, would decompose the test and give rise to red mercuric iodide. The red color produced when ammonium picrate is added to a solution of an alkaline cyanide and heated has been proposed as a test for prussic acid. (P. Guyot, *N. R.*, May, 1877.) It is liable to undergo decomposition if exposed to the light, but it may be kept for a longer time in a bottle covered with black paint or black paper. From experiments carefully conducted by MM. Bussy and Buignet, it appears that, when the alteration in the acid under the influence of light has begun, it will afterwards go on very rapidly in the dark; and that after exposure for a certain time to the light, though no alteration may be apparent, an influence has nevertheless been exerted which disposes to change, and promotes decomposition even in the absence of light. Hence the necessity of immediately enclosing the acid in bottles from which the light is excluded. (*Journ. de Pharm.*, 1863, p. 475.)* Experience has shown that it is best

* Anhydrous hydrocyanic acid sometimes undergoes an apparently spontaneous molecular change by which it is converted into a black solid body, which was supposed to be *paracyanogen* (C_3N_3), or its compounds. This change takes place more slowly in watery solutions of the acid, which are converted into a black liquid; and it is only in a state of extreme dilution, when, for example, water contains not more than one per cent. of the acid, that it is altogether prevented. It sometimes takes place in the official diluted acid; and Prof. Procter exhibited a bottle, which had been most carefully closed, and kept excluded from the light, and in which, nevertheless, the acid had become as black as ink. The cause of this phenomenon remained long unknown: some years ago M. E. Millon satisfied

preserved in cork-stoppered bottles of amber glass; when glass and rubber stoppers were used, decomposition frequently took place rapidly. Its most usual impurities are sulphuric and hydrochloric acids; the former of which may be detected by barium chloride, which will produce a precipitate of barium sulphate, and the latter by precipitating with silver nitrate, when so much of the precipitate as may be silver chloride will be insoluble in boiling nitric acid, while the silver cyanide is readily soluble. The presence of these acids in slight amount is injurious only by rendering uncertain the strength of the medicinal acid, as ascertained by its saturating power. It is now generally acknowledged that mineral acids prevent the deterioration of the dilute prussic acid. But the presence of a mineral acid is not necessary for its preservation; for Dr. Christison has known the medicinal acid from potassium ferrocyanide to keep perfectly well, although barium nitrate did not produce the slightest muddiness. Nevertheless it has been recently shown that much of the acid as kept in the drug-stores is often below the official strength. Various remedies have been proposed. (*P. J. Tr.*, July, 1871; Feb. 1, 1874; Sept. 1874.) One of these is to reduce the strength to one-tenth per cent., this weak solution being said not to undergo change. In our experience a one-per-cent. acid retained its properties through very severe tests of exposure. Mr. John Williams has found in a series of experiments that the addition of 20 per cent. of glycerin has a very pronounced influence in preventing deterioration. (*P. J. Tr.*, Sept. 1874; Sept. 1875.)

Formerly the medicinal acid was of different strengths, as ordered by the different pharmaceutical authorities; but happily the U. S. and Br. Pharmacopœias conform in this important point. At one time its strength was indicated by its specific gravity, which is lower in proportion as it is stronger; but this unprecise mode of estimate is not now relied on; and, though the British Pharmacopœia gives the sp. gr. of its dilute acid at 0·997, both Pharmacopœias give quantitative tests as indices of the strength.

Assay. "To ascertain the percentage strength, mix in a flask (of the capacity of about 100 C.c.) 0·27 Gm. of Hydrocyanic Acid (obtained by distillation as above directed) with sufficient water and magnesia to make an opaque mixture of about 10 C.c. Add to this 2 or 3 drops of potassium chromate test-solution, and then, from a burette, silver nitrate decinormal volumetric solution, until a red tint is produced which does not again disappear by shaking. Each C.c. of silver nitrate volumetric solution used indicates 1 per cent. of absolute Hydrocyanic Acid. After ascertaining the strength of the distillate, dilute it with Distilled Water so as to bring it to the strength of 2 per cent. of absolute acid. Lastly, test the finished product again, when 1·35 Gm. of it should require, for complete precipitation, 10 C.c. of silver nitrate decinormal volumetric solution." *U.S.* This method of assay is based upon Pappenheim's process for the determination of hydrocyanic acid in bitter almond water, as described by Veilhaber in *Archiv d. Pharm.*, 1878, p. 408; the addition of an alkali to a solution of hydrocyanic acid, previous to titration, not only prevents the volatilization of the acid, but, as has been shown by Siebold, the double cyanides of silver with the alkali metals are very permanent. The use of potassium chromate as an indicator, whereby a red color, due to a combination of the chromic acid with the silver, is produced, is highly recommended. The Br. Pharmacopœia directs that "Each gramme of Diluted Hydrocyanic Acid, rendered alkaline by the addition of *solution of sodium hydroxide*, and maintained faintly alkaline throughout the operation, should require the addition of 3·7 cubic centimetres of the *volumetric solution of silver nitrate* before a permanent precipitate begins to form. 5 cubic centimetres evaporated in a platinum dish should leave no residue. It should yield only the slightest reactions with the tests for sulphates or chlorides." To explain this test it is necessary to notice that silver cyanide, though itself insoluble, is rendered soluble by combining with sodium cyanide, in the propor-

himself, by experiment, that the real agency was the presence of ammonia, which may sometimes operate even through the air. It has also been asserted that the cause of the decomposition is the presence of a microscopic plant. (*Journ. de Pharm.*, 1862, p. 48.) The preservative influence of a little sulphuric acid in the diluted hydrocyanic acid would be thus explained; and it is not impossible that the greater resistance offered to the change by the preparation made by the original process, in which sulphuric acid is used, than by the others, may be owing to the influence of this acid, either passing over with its vapor, or acting on the acid vapor before it leaves the retort. An important practical inference from all this is the necessity of providing, as far as possible, that ammonia should in no manner have access to the acid, during or after its preparation. The effect of ammonia in inducing changes in dilute hydrocyanic acid is denied by Pettit. (*A. J. P.*, 1873.) Mr. Rimmington asserts that hydrocyanic acid acts upon the alkali of some varieties of glass. Mr. Siebold, who has confirmed this, declares that the addition of hydrochloric acid is perfectly useless as a preservative, except when the prussic acid is kept in bottles which yield the alkali. (*Pharm. Journ.*, Sept. 1874.) MM. Lescoln and Rigaut (*Comptes-Rendus*, Aug. 4, 1879) state that pure hydrocyanic acid can be preserved for a long time; that the presence of potassium cyanide brings about this decomposition even in the absence of water.

tion of one molecule of each. When, therefore, the diluted hydrocyanic acid is converted, by the addition of soda, into sodium cyanide, no permanent precipitate will begin to appear, upon the addition of silver nitrate, until more than sufficient silver cyanide is produced to form the soluble compound referred to, which happens when one-half of the sodium cyanide has been converted into silver cyanide. An acid of the strength indicated by either of these methods contains two per cent. of anhydrous acid. The test of entire solubility in boiling nitric acid, applied to the precipitate obtained by silver nitrate, is intended to verify its nature; for, if the hydrocyanic acid contained hydrochloric acid, part of this precipitate would be silver chloride, not soluble in the boiling acid. Scheele's medicinal hydrocyanic acid contains about 5 per cent. of anhydrous acid; and therefore two minims of it are equal to five of the U. S. acid. The use of Scheele's acid should be discouraged as unnecessary and very dangerous. In view of the deterioration of hydrocyanic acid upon keeping through loss by volatilization, the following approximate practical test is recommended by Dr. Squibb. If one drop of diluted hydrocyanic acid be added to 15 C.c. of distilled water in one vessel, and one drop of silver nitrate test-solution (U. S. P.) be added to 7 C.c. of distilled water in a test-tube, and the first solution be dropped into the second from a pipette, and the contents be closely observed for a few seconds between the drops, a distinct opalescence should be observed before the fourth drop is added, and should become very marked as the fourth and fifth drops are added.

MM. Fordos and Gélis have proposed, as a test of the strength of the compounds containing cyanogen, an alcoholic solution of iodine of known strength; as, for example, three grains to the fluidounce. The test-solution is added, drop by drop, to the cyanogen compound, until a permanent yellowish tinge is produced. The iodine unites with the cyanogen, and with the substance in combination with the cyanogen, in the ratio of their several equivalents; and hence the cyanogen present is easily calculated from the proportion of iodine expended in uniting with it. This test is commended for its accuracy by Mr. James Roberton, of Manchester, Eng. (See *A. J. P.*, 1853, p. 551.) A. Link and R. Moeckel (*Zeitsch. f. Analyt. Chem.*, 1878, p. 455) made a series of experiments, and showed that the most delicate test for hydrocyanic acid was that of iron sulphocyanate. (*A. J. P.*, 1879, p. 86.)

Properties of the Anhydrous Acid. Hydrocyanic acid, perfectly free from water, is a colorless, transparent, inflammable liquid, of extreme volatility, boiling at 27° C. (80° F.), and congealing at —15° C. (5° F.). Its sp. gr. as a liquid is 0·6969, at the temperature of 18° C. (64° F.); and as a vapor 0·9423. Its taste is at first cooling, then burning, with an after-taste in the throat like that of bitter almonds; but, from its extremely poisonous nature, it must be tasted with the utmost caution. Its odor is so strong as to produce immediate headache and giddiness, and its vapor so deleterious that the smallest portion of it cannot be inhaled without the greatest danger. Both water and alcohol dissolve it readily. It is much more prone to undergo decomposition than the dilute acid. In the course of a few hours it sometimes begins to assume a reddish-brown color, which becomes gradually deeper, till at length the acid is converted into a black liquid, which exhales a strong smell of ammonia. It is a very weak acid in its chemical relations, and reddens litmus but slightly. It does not form solid compounds with metallic oxides, but cyanides of metals, the elements of water being eliminated. According to Sobero, hydrocyanic acid is generated, in sensible quantities, by the action of weak nitric acid on the volatile oils and resins. Wöhler affirmed in 1828 that picric acid when treated with baryta water yields it; and Julius Post and H. Hübner have found that nitrobenzene and dinitrobenzene do also when treated, the former with fusing potassa, the latter with boiling dilute solution of potassa. It has also been formed by the slow action of potassium carbonate on tincture of hyoscyamus, given together as a medicine. (Dr. J. T. Plummer, of Indiana, *A. J. P.*, xxv. 513.) Though a product of art, it exists in some plants, and is generated by reaction between the constituents of many vegetable products upon contact with water. These principles are usually amygdalin and emulsin, but according to Peckholt the root of *Manihot utilissima* copiously generates hydrocyanic acid with water, although he was unable in 15 analyses to find amygdalin in it. (*A. J. P.*, Oct. 1872.) (See *Amygdala Amara.*)*

Composition. Hydrocyanic acid consists of the atomic group cyanogen and one atom of hydrogen; or, in volumes, of one volume of cyanogen and one of hydrogen without con-

* It has been proposed to employ solutions of these vegetable products for the extemporaneous preparation of hydrocyanic acid, and in the Swedish Pharmacopœia the *Emulsio Hydrocyanata* has replaced entirely the dilute prussic acid. An emulsion is first made of 3 parts of sweet almonds, 2 of sugar, and 24 of water. To 80 parts of this emulsion is added one part of amygdalin. In an hour the mixture is ready for use; one ounce of it contains one-third of a grain of anhydrous acid. Dose, one to two teaspoonfuls. (*Nat. Med. Journ.*, July, 1871.)

densation, its formula being HCN or HCy. *Cyanogen*, $(CN)_2$, is a colorless gas, of a strong and penetrating smell, inflammable, and burning with a beautiful bluish-purple flame. Its sp. gr. is 1·8157. It was discovered in 1815 by Gay-Lussac, who viewed it as a compound radical which when combined with hydrogen becomes hydrocyanic acid. Hydrocyanic acid, in a dilute state, was discovered in 1780 by Scheele, who correctly stated its elements to be carbon, nitrogen, and hydrogen; but the peculiar way in which they are combined was first pointed out by Gay-Lussac, by whom also the anhydrous acid was first obtained.

Medical and Toxical Properties. Hydrocyanic acid is one of the most deadly poisons known, and frequently exceedingly rapid in its action. According to Dr. Christison, a grain and a half of the anhydrous acid are capable of producing death in the human subject. One or two drops of the pure acid are sufficient to kill a vigorous dog in a few seconds. Sometimes death occurs almost instantaneously. Usually, however, three stages of the poisoning are manifest: a first, very brief one, of difficult respiration, slow cardiac action, and disturbed nervous action; a second, violent convulsive stage, with dilated pupils, vomiting, often loud cries, unconsciousness, etc.; and a third, closing period, of asphyxia, collapse, and paralysis, sometimes interrupted by convulsions. When smaller doses are ingested, the symptoms come on more slowly, but are similar to those just described, and when paralysis is developed it affects both motility and sensation. A peculiar bloated look of the deeply-suffused face and neck, with frothing at the mouth, occurring along with the symptoms previously described, is almost pathognomonic of the poisoning. The odor of hydrocyanic acid is sometimes very strong, and should always be searched for about the mouth. It is very important as an aid in the diagnosis, but is certainly not always present. Death is usually the result of asphyxia, produced by a direct paralyzing action of the poison upon the respiratory centres. The poison appears also to have a direct paralyzing action upon the heart, and sometimes to produce fatal syncope. The post-mortem appearances are glistening and staring expression of the eyes, gorged state of the venous system with fluid, dark, or bluish-black blood, especially of the veins of the brain and spinal marrow, and sometimes redness of the internal coat of the stomach. The lungs are sometimes natural, at other times turgid with blood. When the death has been very rapid, all of the blood may be found of a bright arterial hue. After a slow death the blood is cyanotic. It is rarely true that all the muscles are insensible to the galvanic current. If the autopsy be not too long deferred, the odor of the acid is generally perceptible when the cadaver is opened. The odor after nitrobenzene poisoning resembles very closely that of the acid, but it is affirmed that the diagnosis can be made by leaving the opened body exposed, when the smell of the acid will disappear, and that of the nitrobenzene remain. Notwithstanding the tremendous energy of this acid as a poison, it has been ventured upon in a dilute state as a sedative, anodyne, and antispasmodic. Though occasionally applied as a remedy prior to 1817, it did not attract very much attention until that year, when Magendie published his observations on its use in diseases of the chest and recommended it to the profession. When given in medicinal doses gradually increased, it produces the following symptoms in different cases: peculiar bitter taste; increased secretion of saliva; irritation of the throat; nausea; disordered respiration; pain in the head; giddiness; faintness; obscure vision; and tendency to sleep. It appears to have a special action on the larynx and trachea. (*Dr. Cogswell.*) The pulse is sometimes quickened, at other times reduced in frequency. It has been extensively used in complaints of the respiratory organs, but later experience has shown that it has but little virtue, except in the quieting of cough. Its influence upon the circulation is not sufficiently pronounced to render the drug of any value as an arterial sedative in acute pulmonary or other inflammations. In *phthisis* it may be resorted to with advantage as a palliative for the cough. In various other affections of the chest attended with *dyspnœa* or *cough*, such as *asthma*, *whooping-cough*, and *chronic catarrh*, it has often been decidedly beneficial, by allaying irritation or relaxing spasm. In certain gastric affections characterized by pain and spasm (*gastrodynia*), and sometimes attended with vomiting, but unconnected with inflammation, and in similar painful affections of the bowels, it has proved beneficial in the hands of several practitioners. In these cases it probably acts locally upon the nerve-endings in the stomach and intestines. It has been used with asserted good results in the paroxysmal excitement of *mania*. (*Ann. de Thérap.*, 1865, p. 111.) Sometimes it is used externally, diluted with water, as a wash in cutaneous diseases. The late Dr. A. T. Thomson insisted particularly on its efficacy in allaying the itching of *impetiginous affections*.

The dose of the diluted hydrocyanic acid is from two to four drops (0·12–0·24 C.c.), dissolved in distilled water, or mixed with gum-water or syrup. It should be administered with the

greatest caution, on account of its minute dose, and its variable strength as usually found. The proper plan, therefore, is to begin with a small dose, two drops, for example, and gradually to increase the quantity until some obvious impression is produced. On account of the rapidity and fugaciousness of its action, it should be given at intervals of not more than two hours; indeed, it is very improbable that the largest therapeutic dose of the substance exerts any influence whatever upon the system one hour after its ingestion. If giddiness, weight at the top of the head, sense of tightness at the stomach, or faintness come on, its use should be discontinued. In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum quantity, lest the new sample should prove stronger than that previously employed. When resorted to as a lotion, from thirty minims to a fluidrachm may be dissolved in a fluidounce of distilled water.

Toxicology. Hydrocyanic acid is so rapidly fatal as a poison that physicians have seldom an opportunity to treat its effects. Death, if it occur at all, usually takes place in from one to forty minutes. One case has, however, been reported in which it was delayed one hour and a quarter. When recovery is brought about, the symptoms in most cases abate very rapidly. The antidotes and remedies most to be relied on are chlorine, ammonia, cold affusion, and artificial respiration. Chlorine in the form of chlorine water, or weak solutions of chlorinated lime or soda, may be exhibited internally, or applied externally. When chlorine is not at hand, water of ammonia, largely diluted, may be given, and the vapor arising from it cautiously inhaled. Cold affusion was first proposed in 1828, by Herbst, of Göttingen, and its utility was subsequently confirmed by Orfila. Its efficacy is strongly supported by experiments performed in 1839 by Dr. Robinson and M. Lonyet upon poisoned rabbits. In a case of poisoning reported by Dr. Christison in 1850, the patient recovered under a stream of cold water poured upon the head from a moderate height. In another case, reported in the *Lancet* in 1854, in which the largest reported quantity was taken to be followed by recovery (2·4 grains of anhydrous acid), the cold-water douche was the principal remedy. (See *Am. Journ. Med. Sci.*, July, 1854, p. 276.) Messrs. T. & H. Smith, of Edinburgh, have recommended especially as an antidote for the medicinal acid a mixture of the ferric salts, swallowed after a solution of potassium carbonate. So soon as the antidote comes in contact with hydrocyanic acid, potassium sulphate is formed, and the poison is converted into Prussian blue. It may be prepared extemporaneously, by adding ten grains of iron sulphate, and a drachm of the tincture of iron chloride, to a fluidounce of water contained in one vial, and twenty grains of potassium carbonate to a fluidounce of water in another vial. The patient is made to swallow the solution of potassium carbonate, and immediately afterwards the mixed ferruginous solution. This quantity is estimated to be sufficient to render insoluble nearly two grains of the anhydrous acid.* In one instance this antidote is said to have proved very effectual. (*P. J. Tr.*, 1865, p. 139.) Hydrogen peroxide (see *Aqua Hydrogenii Dioxidi*) has been found by Kobert to be antidotal, acting by changing the acid into oxamide. (*Pharm. Central.*, 1891.) Johann Antal (*Pharm. Zeitschr. f. Russl.*, 33, 518) recommends cobaltous nitrate as an antidote, and, according to the experiments of Spenzer, it is effective. The action of the poison is, however, so rapid that there is rarely time for any antidote to be of value. Atropine, which has been suggested as physiologically antagonistic to prussic acid, is of no value.

Tests. After suspected death from poison, it is sometimes necessary to ascertain whether the event was caused by this acid. At a period long after death it would be needless to search for so volatile a poison; but it has been recognized three weeks after death, in a case reported by M. Brame, in which about six drachms of acid, containing between 8 and 9 per cent. of anhydrous acid, had been swallowed. The best test is that proposed by Liebig in 1847, consisting in the change of the hydrocyanic acid into ammonium sulphocyanate, which salt is then tested with a ferric salt. Two drops of the acid, so dilute as not to afford the least blue tint with the salts of iron, upon being mixed with a drop of ammonium sulphydrate (yellow

* In a subsequent communication the Messrs. Smith recommend the following proportions. Mix of solution of perchloride of iron (*Br.*) 37 minims, ferrous sulphate, as pure as possible and in fine crystals, 25 grains, and about half a fluidounce of water. Dissolve 77 grains of crystallized sodium carbonate in the same measure of water. These quantities will neutralize between 150 and 200 minims of the medicinal hydrocyanic acid. (*P. J. Tr.*, 1865, p. 147.) Still more recently the authors propose to substitute magnesia for sodium carbonate, as better fitted to neutralize any considerable quantity of gastric acid that might be present. The following is the formula now recommended. From one to two drachms of magnesia, made into a smooth cream with water, are to be first administered, and then 16 minims of solution of perchloride of iron (*Br.*) and 12½ grains of ferrous sulphate are dissolved in water. These quantities are calculated for 100 minims of medicinal hydrocyanic acid. Should more than this be supposed to have been taken, the ferruginous ingredients must be increased in proportion, but not the magnesia. (*Ibid.*, 1865, p. 276.)

from dissolved sulphur), and heated upon a watch-glass until the mixture is colorless, yield a solution of ammonium sulphocyanate which becomes of a deep blood-red color upon the addition of ferric sulphate, in consequence of the formation of iron sulphocyanate. (*Chem. Gaz.*, April 1, 1847; from Liebig's *Annalen.*) This test is praised by Mr. A. S. Taylor, who found it to act characteristically on two grains of dilute hydrocyanic acid, containing only 1-3930th of a grain of anhydrous acid. To render the test thus delicate, Mr. Taylor deems it necessary to evaporate the liquid gently to dryness, after the addition of the ammonium sulphydrate, in order to bring the sulphocyanate to the solid state before adding the iron test, a fractional part of a drop of which will commonly suffice to produce the characteristic color. The red color is instantly discharged by solution of corrosive sublimate or mercuric nitrate, and is thus distinguished from that which might possibly be produced under similar circumstances by acetic acid. Should the acid be mixed with organic matters, Mr. Taylor proposes a modification of Liebig's test, as follows. Place it in a watch-glass, and invert over it another, holding in the centre a drop of ammonium sulphydrate. In from half a minute to ten minutes, without heat, the ammonium sulphydrate will be converted into ammonium sulphocyanate, and upon removing the upper glass, and evaporating its contents to dryness, the iron test will produce the blood-red color. MM. O. Henry and E. Humbert have proposed, as a test of hydrocyanic acid, first to convert it into silver cyanide by distilling the suspected matters into a dilute solution of silver nitrate, and then to decompose the cyanide by iodine, so as to form cyanogen iodide. The dried cyanide is added to half its estimated weight of *pure* iodine, contained in a test-tube. Upon the application of a gentle heat, cyanogen iodide is formed, and characteristic crystals of it are deposited on the cool surface of the tube. (*Journ. de Pharm.*, 1857, p. 173.) Prof. Wormley (*Micro-Chemistry of Poisons*, 2d ed., p. 186) considers the silver nitrate test as the most delicate of all when the hydrocyanic acid vapor is distilled from a mixture and received in a drop of silver nitrate solution placed in a watch-glass above it.

An extremely sensitive test of hydrocyanic acid in the state of vapor has been offered by Schönbein. It consists of white filtering paper imbued with the resin of guaiacum by dipping it in a solution of 3 parts of the resin in 150 of alcohol, and then drying. At the moment of use it is to be moistened with a solution of copper sulphate containing 1 part in 500 parts of water. If now brought into contact with hydrocyanic acid, whether dissolved in water or diffused in the air in the form of vapor, it instantly becomes blue. According to Schönbein, it will change color in air containing only a forty-millionth part of hydrocyanic acid. (See *A. J. P.*, 1869, p. 174.) The test cannot, however, be relied on, since a similar reaction is yielded by numerous other substances, such as nitrous, nitric, and hydrochloric acids, chlorine, bromine, iodine, ammonia, dilute sulphuric acid, chromic acid, potassium bichromate, etc. The paper should be exposed to a current of air drawn through the suspected liquid, and, if indications be yielded, distillation practised to get the volatile acid in a state of sufficient purity to be submitted to the sulphur-iron test. This, as performed by Almén and Strieve, consists in adding ammonium sulphide, to form the sulphocyanate; converting this into the non-volatile potassium sulphocyanate by the addition of a few drops of liquor potassæ; then evaporating nearly or quite to dryness; adding a few drops of water acidulated with hydrochloric acid, and finally adding a drop or two of iron sesquichloride, when the blood red of the sulphocyanate will be developed. (*Boston Med. and Surg. Journ.*, July, 1873.) Another test, which was proposed by Schönbein, and which was found to be exceedingly delicate by M. Büchner, is dependent upon the power prussic acid has of preventing the catalytic action of the red blood-corpuscles. Normally, when these are brought into contact with hydrogen peroxide, the latter is decomposed and oxygen liberated; if prussic acid be present, no oxygen is set free, but the mixture becomes of a deep brown color. In this way Büchner recognized 5 milligrammes of the anhydrous acid in 600 grammes of blood and water. This test is not applicable to old blood. (*A. J. P.*, Sept. 1869.)

A very delicate test proposed for hydrocyanic acid is as follows. About one-half centigramme ($\frac{1}{12}$ grain) of ammonio-ferrous sulphate (or other pure ferrous salt) and the same quantity of uranic nitrate are dissolved in 50 C.c. of water, and 1 C.c. of this test-liquid is placed in a porcelain dish. On now adding a drop of a liquid containing the smallest quantity of prussic acid, a gray purple color or a distinct purple precipitate is produced. (M. Carey Lea, *Amer. Journ. of Sci.* [3], ix. 121–123.)

ACIDUM HYPOPHOSPHOROSUM DILUTUM, U. S. Diluted Hypophosphorous Acid.

(ĂÇ′Ị-DŬM HŸ-PŌ-PHŌS-PHŌ-RŌ′SŬM DĪ-LŪ′TŬM.)

"A liquid composed of about 10 per cent., by weight, of absolute Hypophosphorous Acid [$HPH_2O_2 = 65{\cdot}88$], and about 90 per cent. of water." *U. S.*

This acid has been introduced into the U. S. Pharmacopœia of 1890, mainly because of its value as an addition to pharmaceutical preparations containing iodides liable to decomposition through exposure to light and air. It has proved to be the most satisfactory preservative to these easily decomposed salts. It may be added directly, or, as in the case of syrup of hydriodic acid, a hypophosphite can be employed, and the salt decomposed by an acid during the manipulation. The *National Formulary* has given a very excellent process for its preparation (see Part II.). It may be made on a large scale, however, by decomposing barium hypophosphite with sulphuric acid, or by boiling phosphorus with milk of lime and subsequently decomposing the calcium hypophosphite with a strong acid, oxalic acid being frequently used. The following process of Prof. Procter's (*A. J. P.*, 1858, p. 121) is based on this principle. Take of hypophosphite of lime 480 grains, crystallized oxalic acid 350 grains, distilled water 9 fluidounces. Dissolve the hypophosphite of lime in 6 fluidounces of the water, and the acid in the remainder with the aid of heat; mix the solutions, pour the mixture on a white paper filter, and when the liquid has passed add distilled water carefully till it measures 10 fluidounces; evaporate this to 8½ fluidounces. Charles T. Tyrer prefers to make this acid by decomposing barium hypophosphite carefully with diluted sulphuric acid. It can be made to contain 30 per cent. of real acid; such an acid has the sp. gr. 1·137 and does not deposit on long standing. (*Yearbook of Pharmacy*, 1896, 298.)

Properties. Diluted hypophosphorous acid is a colorless, odorless liquid, having a sour taste and acid reaction; its specific gravity is 1·046 at 15° C. (59° F.). It is miscible in all proportions with water or alcohol. The following official tests are appended:

"When heated in a porcelain capsule, it evaporates, losing at first principally water and becoming more concentrated. On further heating it decomposes, forming hydrogen phosphide which ignites, and phosphoric acid. The pasty residue finally reddens, ignites, and the last portions of phosphorus burn out at higher heat. From silver nitrate test-solution it reduces black metallic silver. When the Acid is gently heated with copper sulphate test-solution, a yellow precipitate of copper hydride falls, which rapidly assumes a reddish-brown color. The addition of hydrogen sulphide test-solution to the Acid should produce neither a precipitate nor a coloration (absence of *lead*, etc.). If some of the Acid be neutralized with ammonia water, separate portions of the liquid should not yield a precipitate with ammonium sulphide test-solution (absence of *iron*, etc)., nor with ammonium oxalate test-solution (absence of *calcium*); nor should more than a slight turbidity be produced by barium chloride test-solution (limit of *phosphoric*, *sulphuric*, *oxalic*, and *tartaric acids*). Neither platinic chloride test-solution nor sodium cobaltic nitrite test-solution should produce more than a slight yellow turbidity in the diluted acid (limit of *potassium*). If 0·5 Gm. of Diluted Hypophosphorous Acid be mixed with 7 C.c. of sulphuric acid and 35 C.c. of potassium permanganate decinormal volumetric solution, and the mixture boiled for fifteen minutes, it should require about 4·7 C.c. of oxalic acid decinormal volumetric solution to discharge the red color, corresponding to about 10 per cent. of absolute Hypophosphorous Acid. To neutralize 6·6 Gm. of Diluted Hypophosphorous Acid should require about 10 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.*

Medical Properties and Uses. This acid is believed by many clinicians to have tonic properties, but is very rarely if ever used except in combinations with strychnine, quinine, or iron, which are thought by many to be especially valuable in *nervous debility*. The dose is from ten to thirty minims (0·62–1·85 C.c.).

ACIDUM LACTICUM. U. S., Br. Lactic Acid.

(ĂÇ′Ị-DŬM LĂC′TỊ-CŬM.)

"An organic acid, usually obtained by subjecting milk-sugar or grape-sugar to lactic fermentation; composed of 75 per cent., by weight, of absolute Lactic Acid [$HC_3H_5O_3 = 89{\cdot}79$], and 25 per cent. of water." *U. S.* "A liquid containing 75 per cent. of hydrogen lactate, $CH_3.CHOH.COOH$, with 25 per cent. of water. It may be produced by the fermentation of lactose." *Br.*

Oxypropionic Acid, Ethidene-lactic Acid; Acide lactique, *Fr.*; Milchsäure, *G.*

Lactic acid was discovered by Scheele. It exists in sour milk, and has been found in a number of the secretions, including the healthy gastric juice, in which its presence has been incontestably proved by Bernard and Barreswil. It has been detected by Prof. Wittstein in the vegetable kingdom, especially in the peduncles of *Solanum dulcamara*, and the liquid which oozes from freshly-cut vine branches. It is a product of the viscous or lactic fermentation of rice-water, or of the juices of the beet, turnip, and carrot. Indeed, it is formed whenever sugar in solution, of whatever kind, is placed in contact with an alkaline or earthy carbonate in presence of a special ferment, as, for example, the casein of milk, or cheese which contains it. Pasteur has demonstrated that the lactic acid fermentation, like the vinous, is caused by a peculiar microscopic plant or mycoderm. It is attended with the production not only of lactic acid, but of other substances also, and among them a peculiar *gum-like substance* in abundance, which, first noticed by Kirchof, has been isolated in a pure state by Brüning. Though similar to arabin and dextrin, with the formula $C_6H_{10}O_5$, it is not exactly identical with either. (See *Chem. Gaz.*, 1858, p. 197.) The lactic acid of fermentation is one of four isomeric acids possessing the formula $C_3H_6O_3$. The *first* of these is the official lactic acid, and is inactive optically. The *second* is identical chemically with this, but physically different, being dextrorotatory, and is found in the juice of flesh. It is called *paralactic acid*. The *third* or *ethylene lactic acid* is found mixed with the second in the so-called "*sarcolactic*" acid extracted from meat. The *fourth* acid has only been obtained synthetically, and is known as *hydracrylic acid*.

Preparation. Lactic acid may be obtained by the following process, which was recommended by M. Louradour as the first step in preparing ferrous lactate. Ferment whey by keeping it at a temperature between 21·1° C. (70° F.) and 26·6° C. (80° F.), whereby it becomes charged with a considerable quantity of lactic acid. Evaporate the liquor to one-third of its bulk, decant and filter, and then saturate with milk of lime. This converts the lactic acid into calcium lactate, which remains in solution, and throws down a precipitate, consisting principally of calcium phosphate. The liquor is filtered again, and precipitated by oxalic acid, which throws down the lime as calcium oxalate, and sets free the lactic acid. By a new filtration a solution of lactic acid is obtained, containing lactose (sugar of milk) and certain salts. From these it may be purified by concentrating it to a syrupy consistence and treating it with alcohol, which dissolves the acid, and precipitates the lactose and foreign salts. The solution is filtered, and the lactic acid is obtained pure by distilling off the alcohol. Wackenroder's method is to mix 10 parts of skimmed milk, 2·5 of milk sugar, 2 of chalk, and 20 of water, to digest at about 23·8° C. (75° F.) for a month, or till the chalk is dissolved, then to express, clarify, and evaporate so as to crystallize the calcium lactate, and, having recrystallized this salt, to decompose it with sulphuric or oxalic acid in exact saturating proportions.

Alan A. Claflin thus describes the manufacture of lactic acid as carried out at the present time on a large scale under the patent of Charles E. Avery (*Journ. Soc. Chem. Ind.*, June 30, 1897). A saccharine solution varying in density from 1·05 to 1·075 is taken. This will contain from 7·5 to 11 per cent. of saccharine matter. It is advantageous to have from 10 to 15 per cent. of this cane sugar, the rest being grape sugar. The saccharine solution, having been made up and boiled for an hour to insure sterilization, is conveyed into the fermentation-tank and cooled to from 55° to 45° C., and then impregnated with nitrogenous matter (such as is extracted from bran by the action of boiling water and dilute acid) in amount equal to about 8 per cent. of the saccharine matter, and the *Bacillus acidi lactici*. In continuous manufacture the ferment solutions are impregnated from a preceding ferment liquor in which a lively fermentation is in progress. 20 per cent. of such impregnating liquor may be added. The impregnation having taken place at 45° C. or over, the temperature is allowed to decrease somewhat as the fermentation grows older. The glucose is practically all decomposed, and the yield of lactic acid is over 98 per cent. As the fermentation progresses the solution must be neutralized with milk of lime, as the limits of acidity in which lactic acid bacteria are healthy are rigidly confined between 0·02 and 0·5 per cent. If the fermenting solution is overneutralized, the butyric ferment will immediately begin to act, and once active is difficult to control. The lactic fermentation is best completed in from three to six days; and when the fermentation is ended, the liquor must be heated sharply to kill all bacteria and spores and prevent subsequent fermentation. The solution is now filtered and evaporated, when the calcium lactate may be crystallized out; or if commercial syrupy acid only is required, the solution may be at once decomposed by sulphuric acid.

Kiliani (*Ber. d. Chem. Ges.*, xv. 136 and 699) has found that lactic acid may be readily prepared by the action of potassium or sodium hydrate upon both grape sugar and invert sugar

(or cane sugar after treatment with dilute acids). He considers invert sugar to be the best material for the preparation of the acid, as it gives a better yield than ordinary glucose, and recommends caustic soda in preference to caustic potash. His procedure is the following: 500 grammes of cane sugar are placed with 150 grammes of water and 10 C.c. of the sulphuric acid, to be used later, in a stoppered flask of 2 litres' capacity and heated for 3 hours to about 50° C. (122° F.). The solution of invert sugar so obtained is colorless, or at most faintly yellow. After cooling there is to be added to it in portions of 50 C.c. at a time 400 C.c. of a caustic soda solution made by dissolving 1 part of caustic soda in 1 part of water. The strong alkali settles at first as a slimy mass on the bottom, and a new portion is only to be added when the mixture has become perfectly homogeneous by shaking. The flask should also be cooled with water while the alkali is being added. The mixture nevertheless becomes colored and greatly heated. Finally the mixture is heated to 60° or 70° C. (140° F.–158° F.) until a test heated over a boiling water-bath does not separate cuprous oxide from Fehling's solution, but gives it only a slight greenish tinge. Into the cooled mixture the calculated amount of sulphuric acid (made by mixing 3 parts of sulphuric acid with 4 of water) is then run. As soon as the acid liquid has cooled to the temperature of the room, a crystal of Glauber's salt is dropped in and the flask dipped in cold water until a thin crystalline crust forms on the sides, which is removed by a rapid shaking of the flask. Cooling and shaking are continued until a crust no longer forms, when the mixture is allowed to stand at rest for 12 to 24 hours. At the end of this time the contents of the flask appear to consist of a crystalline cake soaked with a reddish liquid. There is then added alcohol of 93 per cent., and the whole is shaken up until on further addition no precipitate separates out. The separated Glauber's salt is freed from the alcoholic solution by a vacuum filter, and can be washed with relatively very little alcohol. The half of the alcoholic solution is neutralized over the water-bath with zinc carbonate, filtered boiling hot, and united with the other half. The crystallization begins immediately upon cooling, and is complete after standing 36 hours. The zinc lactate so obtained can be pressed free from mother-liquor and crystallized once, when it is perfectly pure. The weight of this first crystallization amounts to from 30 to 40 per cent. of the sugar used. The concentrated mother-liquor yields yet another portion of nearly pure, although slightly yellowish, crystals. For a method of making lactic acid from corn meal, see *New Remedies*, 1882, p. 235.

George Jacquemin adds the pure lactic ferment, prepared by Pasteur's method, with a quantity of pure sterilized calcium carbonate, to a wort at 45° C. Fermentation is conducted at that temperature, care being taken to exclude dust, to admit filtered air at the bottom of the vessel, and to allow the carbonic acid to escape. Fermentation is complete in five or six days, and the solution of calcium lactate is freed from nitrogenous matters by the addition of tannic acid. The calcium lactate crystallizes out on evaporation of the filtrate. This may be decomposed with an exact quantity of sulphuric or oxalic acid. (*Chem. News*, 1891, lxiv. 62.)

Properties. Lactic acid is a syrupy liquid, nearly colorless, of a slight not unpleasant odor, and a very sour taste. Its sp. gr. is 1·213 at 15° C. (1·21 *Br.*), but acid of this strength is considered as containing only 75 per cent. of absolute lactic acid, the specific gravity of which is 1·248. (Allen, *Commercial Org. Anal.*, 2d ed., i. p. 419.) It is not solidified by evaporation, and not vaporized by a heat not exceeding 160° C. (320° F.). At a higher temperature it emits inflammable vapors. "5 Gm., after combustion, should not leave more than 0.05 Gm. of fixed residue." *U. S.* It unites in all proportions with water, alcohol, and ether, but is nearly insoluble in chloroform. Exposed to a heat of 150° C. (302° F.), it is for the most part converted into a new body, called concrete lactic acid or *lactide*, an anhydride of the formula $C_3H_4O_2$. It coagulates albumen and dissolves a large quantity of freshly precipitated calcium phosphate; a property which doubtless renders it important in the animal economy.

"On adding some potassium permanganate to a mixture of equal volumes of Lactic and sulphuric acids, and gently heating, the odor of aldehyde will become perceptible. 10 C.c. of a 1-per-cent. aqueous solution of the Acid should not be rendered opalescent by the addition of 1 C.c. of silver nitrate test-solution (limit of *chloride*). 10 C.c. of a 10-per-cent. aqueous solution should remain unaffected by the addition of 1 C.c. of barium chloride test-solution (absence of *sulphate*), or by 1 C.c. of copper sulphate test-solution (absence of *sarcolactic acid*), or, after supersaturation with ammonia, by 1 C.c. of ammonium sulphide test-solution (absence of *iron*, *lead*, etc.). On adding a few drops of Lactic Acid to 10 C.c. of hot alkaline cupric tartrate volumetric solution, no red cuprous oxide should be separated (absence of *sugars*). If a small portion of the Acid be heated with an excess of zinc carbonate, the mix-

ture dried at 100° C. (212° F.), and then extracted with absolute alcohol, upon evaporation of the latter no sweet residue should remain (absence of *glycerin*). On mixing equal volumes of Lactic and colorless, concentrated sulphuric acids in a small, clean, glass-stoppered vial, the mixture should not acquire a tint deeper than a pale straw color (absence of more than traces of *organic impurities*). To neutralize 4·5 Gm. of Lactic Acid should require 37·5 C.c. of potassium hydrate volumetric solution (each C.c. corresponding to 2 per cent. of absolute acid), phenolphtalein being used as indicator." *U. S.* "Warmed with *potassium permanganate* it gives the odor of aldehyde. Each gramme should require for neutralization 8·3 cubic centimetres of the *volumetric solution of sodium hydroxide*. Gently warmed, there should be no rancid odor (absence of fatty acids). No turbidity, either permanent or transient, should be produced when the Acid is added drop by drop to twice its volume of *ether* (absence of gum, sugar, mannite, calcium phosphate). It should give no precipitate with *solution of lead subacetate* (absence of malic and sulphuric acids)." *Br.* At the late revision, *diluted lactic acid* (*Acidum Lacticum Dilutum*, *Br.*, 1885) was dropped from the British Pharmacopœia; the old preparation was of the strength of three fluidounces to the pint (Imp. meas.) and had a specific gravity of 1·040.

Medical Properties and Uses. Lactic acid was proposed by Magendie, on account of its being a normal constituent of gastric juice, as a remedy in *dyspepsia*, and for the removal of *phosphatic deposits* in the urine. It is also used in *tuberculous diarrhœa*, and in the *green diarrhœa of children*. The remedy should be taken at the time of meals, in solution sweetened with sugar, prepared like lemonade. From one to three drachms (3·75–11·25 C.c.) may be taken in the course of the day. Professor Cantani, of Naples, was induced by theoretical considerations to employ lactic acid in *diabetes*, in connection with an exclusively meat diet, and reported very remarkable success. (*Ed. Med. Journ.*, 1871, p. 533.) Certain other practitioners have achieved similar results, but the remedy has not answered the expectations formed of it, and is at present not very frequently employed. If used, half a fluidounce in a pint of water should be administered daily. Hypnotic properties have also been ascribed to lactic acid, but the claim has not been verified. In solution the acid has been found very efficacious, locally applied, in dissolving false membrane, and it has consequently been employed, with much apparent advantage, in *diphtheritic affections* and *croup*,* the solution employed containing one part of the acid to five parts of the menstruum. (*Ann. de Thérap.*, 1869, p. 220.) Half a drachm to half an ounce (1·85 C.c. to 14·78 C.c.) may be given to an adult in divided doses during the twenty-four hours.

Lactic acid is a useful addition to medicinal pepsin, increasing the solvent power of that agent upon the food, when taken into the stomach. Some importance has also been attached to it from the supposition that it might be the materies morbi in *rheumatism*, as uric acid has been supposed to be in gout; but in either case the acid is probably the effect rather than the cause of the disease.

ACIDUM NITRICUM. U. S., Br. Nitric Acid.

(ĂṢ'Ị-DŬM NĪ'TRỊ-CŬM.)

"A liquid composed of 68 per cent., by weight, of absolute Nitric Acid [$HNO_3 = 62·89$], and 32 per cent. of water. Nitric Acid should be kept in dark amber-colored, glass-stoppered bottles." *U. S.* "A liquid containing 70 per cent. by weight of hydrogen nitrate, HNO_3, and 30 per cent. of water, prepared by the interaction of sulphuric acid and potassium or sodium nitrate." *Br.*

Acidum Nitri s. Azoticum, Spiritus Nitri Acidus; Spirit of Nitre; Aqua Fortis; Acide nitrique, Acide azotique, *Fr.*; Salpetersäure, *G.*; Zaltpeterzuur, Sterkwater, *Dutch*; Shedwater, *Sw.*; Acido nitrico, *It., Sp.*

Nitric oxide is one of the five compounds formed by nitrogen and oxygen. These are nitrogen protoxide or hyponitrous oxide (laughing gas), N_2O; nitrogen dioxide, N_2O_2 or $(NO)_2$; nitrous oxide, N_2O_3; nitrogen tetroxide or peroxide, N_2O_4; and nitric oxide, N_2O_5. From this latter by the addition of water is formed nitric acid: $N_2O_5 + H_2O = (HNO_3)_2$.

Nitric acid is now official in two forms; the pure acid of the sp. gr. 1·42, and the diluted. The strong acid, of the sp. gr. 1·5, has long been abandoned.

* *Lactic Acid Sticks.* Zippel proposes to use lactic acid in the form of sticks for *tuberculous fistulas*, etc. 50 Gm. each of gelatin, lactic acid, and water are melted at a gentle heat, 30 Gm. of menthol added, and poured into moulds. After allowing the moulds to remain in the ice-box for 24 hours, the sticks are taken out, and dried over calcium chloride. The sticks are afterwards coated with collodion, or kept under oil, to prevent deliquescence. (*Zeits. Oester. Apoth. Ver.*, 1892, 222.)

Preparation. The usual practice adopted in the laboratory for obtaining nitric acid is to add to potassium nitrate in coarse powder, contained in a retort, an equal weight of strong sulphuric acid, poured in by means of a tube or funnel, so as not to soil the neck. The materials should not occupy more than two-thirds of the capacity of the retort. A receiver being adapted, heat is applied by means of a spirit- or gas-lamp, the naked fire, or a sand-bath, moderately at first, but afterwards more strongly when the materials begin to thicken, in order to bring the whole into a state of perfect fusion. Red vapors will at first arise, and afterwards disappear in the course of the distillation. Towards its close they will be reproduced, and their reappearance will indicate that the process is completed.

The proportion of equal weights, as above given, corresponding nearly to one mol. of potassium nitrate and one of sulphuric acid, is the best for operations on a small scale in the laboratory.

A practical disadvantage in this method of obtaining very strong nitric acid is that, owing to the high heat and the presence of the crystals, the retort is frequently fractured. Prof. Trimble recommends adding one part of commercial nitric acid to two parts of strong sulphuric acid in a retort and distilling slowly until the nitric acid is all collected.*

Monohydrated Nitric Acid. *Hydrogen Nitrate.* This is the strongest liquid nitric acid that can be procured, and may be supposed to be obtained by distilling one molecule of pure and dry nitre with one molecule of monohydrated sulphuric acid. One molecule of monohydrated nitric acid distils over, and one molecule of potassium bisulphate remains behind: $KNO_3 + H_2SO_4 = HNO_3 + HKSO_4$. Acid of this strength is very difficult to make, and requires for its preparation the most elaborate attention to separate the superabundant water. According to Mr. Arthur Smith, of London, acid dehydrated as far as possible is perfectly colorless, boils at 84° C. (184° F.), has the sp. gr. 1·517 at 15·4° C. (60° F.), and nearly approaches, in composition, to a monohydrate. Acid of this strength, even at the boiling temperature, has not the slightest action on tin or iron. (*Phil. Mag.*, Dec. 1847.) According to Kolb (*Ann. Chem. Phys.* [4], x. 140), the true HNO_3 has a sp. gr. at 15° C. (59° F.) as high as 1·530.

The acid of the former Br. Pharmacopœia, having the sp. gr. 1·5, is of a yellowish color, and strongly corrosive. Strictly speaking, it is hydrogen nitrate diluted with half a molecule of water ($HNO_3 + \frac{1}{2}H_2O$). An acid of this strength is inconveniently strong, is constantly undergoing decomposition under the influence of light, and was consequently replaced by a pure acid of the density 1·42. This substitution was made in the U. S. Pharmacopœia of 1850, and in the British of 1867.

Nitric Acid (sp. gr. 1·42 and 1·414). This is the acid now official in both the U. S. and Br. Pharmacopœias. Acid of the density 1·5 was not usually found in commerce, and much pains was required to get it of that strength. Besides, acid of this density was not necessary for any process of the Pharmacopœia. Considerations of this kind induced the revisers of our national standard of 1850 to lower the strength of official nitric acid to 1·42, its purity in other respects remaining the same. In the Pharmacopœia of 1890 the strength has again been very slightly reduced from 1·42 to 1·414, since it has been shown that 68-per-cent. acid has this specific gravity, the acid of U. S. P. 1880, of the specific gravity 1·42, having an inconvenient fraction in its percentage (69·4 per cent.).

"If 1 C.c. of Nitric Acid be slightly supersaturated with ammonia water, no precipitate should be formed (absence of *iron*, or *much lead*); nor should the liquid assume a blue tint (*copper*); nor should the further addition of a few drops of colorless ammonium sulphide test-solution produce any coloration or precipitate (*lead*, *iron*, *copper*, etc.). On diluting some of the Acid with 5 times its volume of water, a portion of this liquid, when gently heated and treated with freshly prepared hydrogen sulphide test-solution, should not show a colored precipitate (absence of *lead*, *arsenic*, *copper*); nor should any precipitate be produced in other portions of the diluted Acid by barium chloride test-solution (absence of *sulphuric acid*), or by silver nitrate test-solution (absence of *hydrochloric acid*). If the diluted Acid be shaken with

* *Pure Concentrated Nitric Acid—Preparation.* Lunge and Rey obtain pure, colorless, concentrated nitric acid by the following method. A quantity of nitric acid, prepared and deprived of coloring impurities in the usual manner, and containing 98·7 per cent. of absolute nitric acid, was put into a retort together with twice its volume of absolute sulphuric acid (H_2SO_4), and distilled *in vacuo*, the pressure being reduced to 20 Mm. by means of a water-jet pump. This was found to be the only way to prevent the acid from becoming yellow. The connection between the neck of the retort and the receiver was effected by wrapping with asbestos-paper and an external coat of moulder's clay. Great care was taken to insure the absence of organic matter. The distillation took place at a temperature of 35° C. (95° F.), and the distillate was completely colorless. It contained 99·7 per cent. of HNO_3. (*Amer. Drug.*, June 1, 1891, 170; from *Ztschr. f. Analyt. Chem.*)

a few drops of chloroform, the latter should remain colorless (absence of *iodine* or *bromine*), even after introduction of a small piece of metallic zinc (absence of *iodic* or *bromic acid*). To neutralize 3·145 Gm. of Nitric Acid should require 34 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 2 per cent. of absolute acid), phenolphtalein being used as indicator." *U. S.* "Each gramme diluted with *water* should require for neutralization 11·1 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, chlorides, bromates, iodates, or sulphates. It should yield no residue or not more than 0·005 per cent. on evaporation to dryness." *Br.*

To correspond with the tests given in the U. S. P., it must be colorless, and entirely volatilizable by heat; must dissolve copper, silver, and other metals with evolution of red vapors, and stain woollen fabrics and animal tissues a bright yellow. Acid of the density 1·42 is the most stable of the hydrated compounds of nitric acid, and boils at 121° C. (250° F.), 1·414 acid boiling at 120·5° C. (248·9° F.). When either stronger or weaker than this, it distils over at a lower temperature, and, by losing more acid than water in the first case, and more water than acid in the second, constantly approaches to the sp. gr. 1·42, when its boiling point becomes stationary. These facts in relation to nitric acid of this strength were first observed by Dalton, and have since been confirmed by Mr. Arthur Smith, of London. This acid may be assumed to have the composition $HNO_3 + 1\frac{1}{2}H_2O$.

Nitric Acid of the Arts. Two strengths of this acid occur in the arts: *double aqua fortis* (sp. gr. 1·36), which is of half the strength of concentrated nitric acid, and *single aqua fortis* (sp. gr. 1·22), which is half as strong as the double. Aqua fortis is sometimes obtained by distilling a mixture of nitre and calcined ferric sulphate. By an interchange of ingredients, potassium sulphate and ferric nitrate are formed, the latter of which, at the distilling heat, readily abandons its nitric acid. The potassium sulphate is washed out of the residue, and the iron sesquioxide which is left is sold, under the name of *colcothar*, to the polishers of metals. The distillation is performed in large cast-iron retorts, lined on the inside with a thick layer of red ferric oxide, to protect them from the action of the acid. The acid is received in large glass vessels containing water. A considerable portion of the acid is decomposed by the heat into reddish vapors, which subsequently dissolve in the water and absorb the oxygen which had been disengaged. The acid thus obtained is red and tolerably strong, but is diluted with water before being sold.

The reddish acid called *nitrous acid* is nitric acid containing more or less nitrogen tetroxide (N_2O_4). The same acid may be formed by impregnating, to a limited extent, nitric acid with nitrogen dioxide (N_2O_2). If the saturation be complete, every two molecules of nitric oxide become three molecules of nitrogen tetroxide by the aid of one molecule of nitrogen dioxide ($2N_2O_5 + N_2O_2 = 3N_2O_4$). The commercial nitrous acid may be converted into nitric acid by exposing it to a gentle heat. As nitrogen tetroxide (N_2O_4) forms, in contact with bases, a nitrate and nitrite, there being no hyponitrates, some chemists consider it as a compound of nitric and nitrous oxides ($2N_2O_4 = N_2O_5 + N_2O_3$).

In making nitric acid on the commercial scale, sodium nitrate is substituted for nitre, as it is much cheaper, and the salt is decomposed with sulphuric acid as before. The proportions of these two substances employed are not the same in all works. If one molecule of sulphuric acid and two of sodium nitrate be taken, the following are the reactions: $H_2SO_4 + NaNO_3 = NaHSO_4 + HNO_3$. When the heat is raised, the acid sodium sulphate acts upon a second molecule of sodium nitrate, thus: $NaHSO_4 + NaNO_3 = Na_2SO_4 + HNO_3$. In this case a part of the acid is decomposed, owing to the high temperature, and nitrogen peroxide is evolved in the form of red fumes, which dissolve in the concentrated acid, giving it the red appearance usually noted in the strong commercial product. When a large excess of sulphuric acid is employed, some acid sodium sulphate is formed, which lowers the melting point of the residual mass so that it can be withdrawn from the retorts in a fused state, whereas in the other case the residue can only be removed in the solid state after the cylinder has cooled.

The ordinary commercial acid has a specific gravity of from 1·30 to 1·41, and is usually prepared by means of chamber (sulphuric) acid; but if a more concentrated acid is required, a stronger sulphuric acid must be employed. The strongest nitric acid occurring in commerce has a sp. gr. of 1·43, and this is obtained by distilling well-dried Chili saltpetre with sulphuric acid having a sp. gr. of 1·85.

The retorts in which nitric acid is usually prepared in England consist of cast-iron cylinders, built in a furnace in such a way that they may be heated as uniformly as possible. Some

manufacturers cover the upper half of the cylinder with fire-bricks, in order to protect the iron from the action of the nitric acid vapors. This is unnecessary, however, if the retorts are so thoroughly heated that no nitric acid condenses on the surface of the iron.

M. Mallet, of Paris, has proposed to obtain nitric acid by distilling sodium nitrate with well-dried boric acid, sodium biborate or borax being the residue. Another method, employed by Kuhlmann, is to expose a mixture of sodium nitrate and manganese chloride to a heat of about 232° C. (450° F.), and to pass the mixed gases which escape through water. Hyponitric acid and oxygen are disengaged, which become nitric acid when they enter the water. (*P. J. Tr.*, 1862.)

General Properties of Nitric Acid. Nitric acid, so called from nitre, is an extremely sour and corrosive liquid. It was discovered by Raymond Lully, in the thirteenth century, and its constituents by Cavendish, in 1784. When perfectly pure it is colorless; but, as usually obtained, it has a straw color, owing to the presence of hyponitric acid. The concentrated acid, when exposed to the air, emits white fumes, possessing a disagreeable odor. By the action of light it undergoes a slight decomposition, and becomes yellow. It acts powerfully on animal matter, causing its decomposition. On the living fibre it operates as a strong caustic. It stains the skin and most animal substances of an indelible yellow color. On vegetable fibre it acts peculiarly, abstracting hydrogen or water, and combining with the remaining elements. When diluted, nitric acid converts most animal and vegetable substances into oxalic, malic, and carbonic acids. The general character of its action is to impart oxygen to other bodies, which it is enabled to do, as oxygen in the nascent state is liberated in its decomposition. If this liberation take place while in contact with bodies capable of oxidation, the oxygen goes to effect this oxidation. Free nitric acid, however, will evolve oxygen at a red heat, according to the following reaction:

$$4HNO_3 = (N_2O_4)_2 + O_2 + (H_2O)_2.$$

It oxidizes sulphur and phosphorus, giving rise to sulphuric and phosphoric acids, and all the metals, except chromium, tungsten, columbium, cerium, titanium, osmium, rhodium, gold, platinum, and iridium. It combines with salifiable bases and forms nitrates. When mixed with hydrochloric acid, mutual decomposition takes place, according to the reaction $HNO_3 + 3HCl = NOCl + Cl_2 + 2H_2O$, and nitrohydrochloric acid is formed.

Great care must be used in transporting nitric acid, for if the strong acid come in contact in quantity with vegetable substances like hay, tow, excelsior, paper, etc., fire will be apt to occur. The occurrence of such accidents was proved by the official inquiry of Prof. R. Haas. (*Ber. d. Chem. Ges.*, 1881, 597.) A trace of nitric acid has been detected in the atmosphere. It is said to be always present in the air in summer. (*Kletsinsky.*)

Tests. Nitric acid, when uncombined, is recognized by its dissolving copper with the production of red vapors, and by its forming nitre when saturated with potassa. When in the form of a nitrate, it is known by its action on gold-leaf, after the addition of hydrochloric acid, in consequence of the evolution of chlorine; or it may be discovered, according to Dr. O'Shaughnessy, by heating the supposed nitrate in a test-tube with a drop of sulphuric acid, and then adding a crystal of morphine. If nitric acid be present, it will be set free by the sulphuric acid, and reddened by the morphine. The same effect is produced by brucine, by commercial strychnine, on account of its containing brucine, and still more strongly, according to M. Braun, by aniline sulphate, which affords an exceedingly delicate test. (*Journ. de Pharm.*, 1867, p. 157.) To prevent all ambiguity arising from the accidental presence of nitric acid in the sulphuric acid employed, the operator should satisfy himself, by a separate experiment, that the latter acid has no power to produce the characteristic color with morphine. Another test for nitric acid is to add *pure* sulphuric acid to the concentrated liquid suspected to contain it, together with a little concentrated solution of ferrous sulphate. The smallest trace of nitric acid affords, when the mixture is warmed, a pink red color; and if it be present in considerable amount, the liquid becomes almost black.* Rosa recommends the use of ammonio-ferrous sulphate, in place of ferrous sulphate, as a test for nitric acid. It is

* *A quantitative test for nitric acid* in water, first proposed by M. Boussingault, in 1857, was simplified by M. Marx, and finally perfected by M. Fischer, who substituted indigotin for indigo, on account of its solution being permanent. His method is first to prepare a test-solution by mixing 5 cubic centimeters of solution of indigotin with 30 cubic centimeters of pure sulphuric acid, and then adding a titrated solution of potassium nitrate (5 decigrammes to the litre) until the blue color is changed to a faint green. Then the solution of indigotin is diluted until one cubic centimeter is decolorized by 0·2525 milligramme of potassium nitrate. In using this test-solution the temperature should always be at least 110° C. (230° F.), and the amount of sulphuric acid should always be at least double the joint volume of the indigotin solution and the water. (*Journ. de Pharm.*, Nov. 1874.)

more stable than the latter, either in crystals or in solution. Equal measures of the liquid to be tested for nitric acid and of concentrated sulphuric acid are mixed, the mixture cooled, and then a layer of solution of ammonio-ferrous sulphate poured slowly on top; if even a trace of nitric acid be present, a brown zone will form at the line of contact of the liquids. (*Am. Drug.*, 1886, p. 13.) For official tests of purity, etc., see pages 69 and 70.

A method particularly useful in the determination of the nitrates contained in drinking-water depends upon the fact that a thin zinc plate, which has been covered with a deposit of spongy metallic copper by dipping it in a solution of copper sulphate, on being heated with water containing nitrates reduces them to ammonia, zinc hydroxide and free hydrogen also being formed (*Gladstone* and *Tribe*), thus: $KNO_3 + 4H_2 = NH_3 + KOH + 2H_2O$.

The nitric acid of commerce sometimes contains iodine, probably derived from the native sodium nitrate, in which iodate frequently occurs. This may be reduced by passing hydrogen sulphide into the diluted acid, taking care not to use an excess. A few drops of chloroform or carbon disulphide shaken up with the liquid will then show the iodine color. Still better is the test proposed by Mr. Stein, which is to introduce a stick of tin into the suspected acid, and, after red vapors have begun to escape, to withdraw the metal, add a few drops of carbon disulphide, and agitate. If iodine be present, the drops of the sulphide which soon separate will be colored more or less deeply red, according to the amount of impurity. These impurities, however, do not affect the medical properties of the acid.

The following table of Lunge and Rey is the recognized standard at present:

Table showing percentage of absolute Nitric Acid in Nitric Acid of different densities, at 15° *C.* (59° *F.*).

Composition. The composition of the official acid of the density 1·414 has already been given. It contains about 75 per cent. of nitric acid of the sp. gr. 1·5. Nitric oxide or anhydride consists of two atoms of nitrogen and five atoms of oxygen; or, in volumes, of two volumes of nitrogen and five volumes of oxygen, supposed to be condensed, to form nitric oxide vapor, into two volumes. In 1849 the interesting discovery was made by M. Deville, of Besançon, of the means of isolating nitric oxide or anhydride. The method pursued was to pass perfectly dry chlorine over silver nitrate. The oxide is in the form of colorless, brilliant, limpid crystals, which melt at 29·5° C. (85° F.) and boil at 45° C. (113° F.). In contact with water they form a colorless solution with evolution of heat, without the disengagement of gas. (*Journ de Pharm.*, 1849, p. 207.)

Medical Properties. Nitric acid is tonic, antiseptic, astringent, and appears to act upon the intestinal glands in some way so as to modify their function. It is a very useful remedy in cases of *intestinal indigestion:* in this it resembles hydrochloric acid: the choice between the two acids in any individual case should be guided by the existence or non-existence of diarrhœa, the nitric acid being given when there is looseness of the bowels. In *syphilis*, and in the *chronic hepatitis* of India, this acid was highly extolled by Dr. Scott, formerly of Bombay. It has occasionally excited ptyalism. It cannot be depended upon as a remedy in syphilis, but, in worn-out constitutions, is often an excellent adjuvant. In hepatic troubles it is markedly inferior to the nitrohydrochloric acid, unless, it may be, when there is much diarrhœa. As nitric acid dissolves both *uric acid* and the *phosphates*, it was supposed to be applicable to cases of *gravel* in which the uric acid and the phosphates are mixed; but experience has not confirmed the opinion. Nevertheless, when the sabulous deposit depends upon disordered digestion, this acid may prove serviceable by restoring the tone of the stomach. The dose is from five to ten minims (0·3–0·6 C.c.), in three fluidounces or more of water, three or four times a day.

Externally, nitric acid has been used with advantage as a lotion to *ulcers*, in the strength of about twelve minims to the pint of water. This practice originated with Sir Everard Home, and is particularly applicable to those *ulcers* which are superficial and not disposed to cicatrize. In sloughing *phagedæna*, *strong* nitric acid is one of the best remedies, applied by means of a piece of lint tied round a small stick, or by the use of a glass brush. Sometimes a piece of lint is soaked with the strong acid, and pressed into the sore, being allowed to remain for several hours. In *cancrum oris*, concentrated nitric acid, freely applied, is one of the best local remedies that can be employed for arresting the phagedænic ulceration and disposing the sore to heal, but great care must be exercised to protect the teeth. The *strong* acid is also used as an escharotic in *venereal ulcers* and other affections. Nitric acid vapors were formerly used as a disinfectant. Half an ounce of powdered nitre was put into a saucer, placed in an earthen dish containing heated sand, and two drachms of sulphuric acid were then poured over it.

Properties as a Poison. The swallowing of concentrated nitric acid is at once followed by burning heat in the mouth, œsophagus, and stomach, acute pain, disengagement of gas, abundant eructations, nausea, and hiccough. These effects are soon followed by repeated and excessive vomiting of matter having a peculiar odor and taste, tumefaction of the abdomen with exquisite tenderness, a feeling of coldness on the surface, horripilation, icy coldness of the extremities, small depressed pulse, great anxiety, continual tossings and contortions, and extreme thirst. The cases are almost always fatal. Sometimes the collapse has been immediate and has masked all the other symptoms. The best remedies are repeated large doses of alkaline solutions, soap, magnesia, chalk, as antidotes, mucilaginous drinks in large quantities, olive or almond oil in very large doses, emollient fomentations, etc.

ACIDUM NITRICUM DILUTUM. U. S., Br. Diluted Nitric Acid.

(ĂQ'I-DŬM NĪ'TRI-CŬM DI-LŪ'TŬM.)

"100 parts by weight should contain 17·44 parts of hydrogen nitrate, HNO_3." *Br.*

Acide azotique dilué, *Fr.;* Verdünnte Salpetersäure, *G.*

"Nitric Acid, *one hundred grammes* [or 3 ounces av., 230 grains]; Distilled Water, *five hundred and eighty grammes* [or 20 ounces av., 201 grains], To make *six hundred and eighty grammes* [or 23 ounces av., 431 grains]. Mix them. Keep the product in dark amber-colored, glass-stoppered bottles." *U. S.*

"Nitric Acid, 3 *fl. ounces and* 7 *fl. drachms* (more exactly, 3·86 *fl. ounces*, Imperial measure) or 2400 *grains*, or 193·2 cubic centimetres or 274·3 grammes; Distilled Water, a sufficient quantity. Introduce the Nitric Acid into a glass flask, the capacity of which to a mark on the neck is *one pint* (Imp. meas.) or one thousand cubic centimetres; add Distilled Water

until the mixture, at 60° F. (15·5° C.), measures *one pint* (Imp. meas.) or one thousand cubic centimetres)." *Br.*

The U. S. acid, as now directed, does not vary appreciably from that formerly official. "Diluted Nitric Acid contains 10 per cent., by weight, of absolute Nitric Acid. Specific gravity, about 1·057 at 15° C. (59° F.). It corresponds in properties to Nitric Acid (see *Acidum Nitricum*), and should conform to the same reactions and tests. To neutralize 6·29 Gm. of Diluted Nitric Acid should require 10 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of absolute acid), phenolphtalein being used as indicator." *U. S.*

The British diluted acid is considerably stronger than our own in the same measure. It has the sp. gr. 1·101; and "Each gramme should require for neutralization 2·7 cubic centimetres of the *volumetric solution of sodium hydroxide*." *Br.* In making the U. S. diluted acid, pharmacists should be careful to use acid of the sp. gr. 1·414; or, if the acid be weaker, to add proportionally less water; otherwise the diluted acid would be weaker than is directed in the Pharmacopœia.

The medicinal properties of the diluted acid are the same as those of the strong acid. (See *Acidum Nitricum*.) Dose of U. S. diluted acid, from twenty to forty drops or minims (1·25–2·5 C.c.), that of the British, from fifteen to thirty drops (0·9–1·9 C.c.), properly diluted.

ACIDUM NITROHYDROCHLORICUM. U. S. Nitrohydrochloric Acid.

[Nitromuriatic Acid.]

(ĂC′I-DŬM NĪ-TRŌ-HĬ-DRŌ-ȻHLŌ′RĪ-CŬM.)

Acidum Chloro-nitrosum, *G.*; Acidum Nitromuriaticum, *Pharm.* 1870; Acide chlorazotique, Eau régale, *Fr.*; Salpetersalzsäure, Königswasser, *G.*

"Nitric Acid, *one hundred and eighty cubic centimeters* [or 6 fluidounces, 41 minims]; Hydrochloric Acid, *eight hundred and twenty cubic centimeters* [or 27 fluidounces, 5 drachms, 48 minims]. Mix the acids in a capacious glass vessel, and, when effervescence has ceased, pour the product into dark amber-colored, glass-stoppered bottles, which should not be more than half filled, and keep them in a cool place."* *U. S.*

Nitrohydrochloric acid is the *aqua regia* of the earlier chemists, so called from its property of dissolving gold. Nitric and hydrochloric acids, when mixed together, are mutually decomposed. According to the researches of Gay-Lussac, the reaction gives rise to two compounds, NO_2Cl (nitroxyl chloride) and NOCl (nitrosyl chloride), mixed with free chlorine. Later researches seem, however, to show that the latter of the two chlorides exclusively is produced, the reaction for the decomposition of aqua regia being $HNO_3 + 3HCl = 2H_2O + NOCl + Cl_2$.

The power of nitrohydrochloric acid to dissolve gold, and similar metals having a weak affinity for oxygen, is owing exclusively to the free chlorine present, and is in no wise dependent on the compound above referred to, which remains entirely passive during the solution of the metal. When nitrohydrochloric acid is made from strong acids, there is always a loss of the nitrosyl chloride and of free chlorine by effervescence, in consequence of the acids not containing sufficient water to hold the gaseous products in solution. Hence the substitution, in the former Pharmacopœia, of nitric acid of 1·42 for the acid of 1·5 was an improvement.

Properties. A golden-yellow, fuming, and very corrosive liquid, having a strong odor of chlorine and a strongly acid reaction. By heat it is wholly volatilized. It readily dissolves gold-leaf, and a drop added to potassium iodide test-solution liberates iodine abundantly. Nitrohydrochloric acid has an orange color, soon changing to a golden yellow, and the odor of chlorine. It possesses the power of dissolving gold and platinum. It should be kept in a cool dark place, on account of its liability to lose chlorine by heat, and to have its chlorine converted into hydrochloric acid by the action of light and the decomposition of water. On account of its tendency to decomposition, it should not be made in large quantities, nor be kept very long by the apothecary; and care should be taken not to transfer it to the bottle in which it is to be dispensed, until effervescence has ceased, lest the pressure within should drive out the stopper. Nitric and hydrochloric acids, as found in commerce, are sometimes so weak that when mixed they will not readily act on gold-leaf. In this case their solvent power may be rendered effective by the addition of a little sulphuric acid, which, by its superior affinity for water, concentrates the other acids, and causes immediate action.

Medical Properties and Uses. Nitrohydrochloric acid was brought to the notice of the profession in consequence of the favorable report of its efficacy as an external remedy

* For an apparatus for making nitrohydrochloric acid upon a large scale, see *P. J. Tr.*, xi. 422.

in *hepatitis*, made by Dr. Scott, formerly of Bombay. When thus employed, it produces a tingling sensation of the skin, thirst, a peculiar taste in the mouth, and occasional soreness of the gums and plentiful ptyalism, and at the same time stimulates the liver, as is evinced by an increased flow of bile. It is used either by sponging or in the form of a local or general bath. When applied by sponging, the acid is first diluted so as to have the sourness of strong vinegar. When used as a foot-bath, three gallons of water, contained in a deep narrow wooden tub, may be acidulated with six fluidounces of the acid. In this the feet and legs are to be immersed for twenty minutes or half an hour. The bath may be employed at first daily, and afterwards twice or thrice a week; and the sponging may be used at the same time. The bath is said to be effective in promoting the passage of *biliary calculi*. The solution, prepared for a bath as above mentioned, may be used for a week, adding to it daily a pint of water acidulated with two fluidrachms of the acid, to make up for the waste by evaporation. The bath should have a temperature of about 97° F., which may be attained by heating part of the acid solution and throwing it back into the remainder.

Nitrohydrochloric acid is much used internally, and it is an excellent remedy in chronic *hepatic affections*, in *oxaluria*, and in *dyspepsia* with a tendency to constipation. It is sometimes given also in *syphilitic diseases*. The strong fresh acid is preferable to the dilute, and may be given in doses of from three to six drops (0·18–0·36 C.c.), well diluted, after meals, care being exercised to prevent its injuring the teeth. It should never be prescribed in combination with strong alcoholic liquids undiluted, as gases may be generated in sufficient volume to cause explosion. (See *A. J. P.*, 1878, p. 67.)

ACIDUM NITROHYDROCHLORICUM DILUTUM. U. S., Br. Diluted Nitrohydrochloric Acid. [Diluted Nitromuriatic Acid.]

(ĂṢ′Ị-DŬM NĪ-TRṌ-HĪ-DRṌ-ȻHLŌ′RỊ-CŬM DỊ-LŪ′TŬM.)

"An aqueous solution of free chlorine, hydrochloric, nitric, and nitrous acids." *Br.*

Acidum Nitromuriaticum Dilutum, *Pharm.* 1870; Acide chlorazotique dilué, *Fr.;* Verdünnte Salpetersalzsäure, *G.*

"Nitric Acid, *forty cubic centimeters* [or 1 fluidounce, 2 fluidrachms, 49 minims]; Hydrochloric Acid, *one hundred and eighty cubic centimeters* [or 6 fluidounces, 41 minims]; Distilled Water, *seven hundred and eighty cubic centimeters* [or 26 fluidounces, 3 fluidrachms]. Mix the Acids in a capacious glass vessel, and, when effervescence has ceased, add the Distilled Water. Keep the product in dark amber-colored, glass-stoppered bottles, in a cool place." *U. S.*

"Nitric Acid, 3 *fl. ounces* (Imperial measure) or 60 cubic centimetres; Hydrochloric Acid, 4 *fl. ounces* (Imp. meas.) or 80 cubic centimetres; Distilled Water, 25 *fl. ounces* (Imp. meas.) or 500 cubic centimetres. Mix the Acids with the Distilled Water, and keep the mixture in a glass-stoppered bottle for fourteen days before it is used. Colorless, with a pungent acid taste and odor. Specific gravity 1·07. 4 grammes should require for neutralization about 10 cubic centimetres of the *volumetric solution of sodium hydroxide*. *Br.*

"A colorless, or pale yellowish liquid, having a faint odor of chlorine, a very acid taste and reaction. By heat it is wholly volatilized. On adding a few drops to potassium iodide test-solution, iodine is liberated." *U. S.*

Between diluted nitric and hydrochloric acids no reaction occurs; and therefore the U. S. Pharmacopœia directs that the acids shall be mixed before dilution. But according to the researches of Mr. Tilden, confirmed by Mr. Redwood (*P. J. Tr.*, x. 508), water determines a decomposition of the products resulting from the reaction between nitric and hydrochloric acids, and the reformation of hydrochloric and nitric acids, with a little nitrous acid. It would seem, therefore, that diluted nitrohydrochloric acid is not an eligible preparation, a conclusion confirmed by clinical experience. The dose is from ten to twenty drops or minims (0·6–1·25 C.c.).

ACIDUM OLEICUM. U. S., Br. Oleic Acid.

$HC_{18}H_{33}O_2$; 281·38. (ĂṢ′Ị-DŬM Ọ-LĒ′Ị-CŬM.) $HC_{18}H_{33}O_2$; 282.

"An organic acid, prepared in a sufficiently pure condition by cooling commercial Oleic Acid to about 5° C. (41° F.), then separating and preserving the liquid portion." *U. S.* "Oleic Acid, $CH_3(CH_2)_7CH : CH(CH_2)_7COOH$, or hydrogen oleate, is obtained by the saponifying action of alkalies and subsequent action of acids, or by the action of superheated steam, upon the olein of fats. Usually not quite pure." *Br.*

Acide oléique, *Fr.;* Oleinsäure, *G.*

This acid, although known for many years, was not used medicinally until 1872 (*London Lancet*, 1872, p. 709), when Prof. John Marshall introduced the oleates to the profession as

substitutes for some of the older ointments, stating that they are not only cleaner and more elegant, but also much more efficacious. (See *Oleata.*)

Preparation. The difficulty in preparing oleates of good quality arises usually from the use of the commercial oleic acid, which, being obtained as a by-product in the manufacture of glycerin and candles, has a reddish-brown color and a disagreeable fatty odor. It is almost always contaminated with stearic and palmitic acids with undecomposed glycerides when obtained by the autoclave process, and hydrocarbons when obtained by the distillation of the fat acids. Various processes have been suggested for the purification of oleic acid. Charles Rice (*A. J. P.*, xlv. 2) exposes the commercial acid to a temperature of 4° C. (39° F.), and expresses the liquid portion, which is oleic acid deprived of the greater part of the contaminating substances. The odorous and coloring principles are not removed by this process. A writer in *A. J. P.* (xlv. 97) prepares *oleic acid* for making oleates by saponifying almond oil with potassa; decomposing by tartaric acid, separating the precipitated bitartrate; heating for several hours on a water-bath with half its weight of finely powdered lead oxide; after cooling, mixing with three times its volume of ether, settling, decanting, and treating the residue with ether as before; agitating the mixed ethereal solutions with dilute hydrochloric acid; skimming off the ethereal solution of oleic acid, washing it with water, reskimming, and recovering the ether by distillation. L. Wolff (*A. J. P.*, 1879) saponifies oil of sweet almond with lead oxide, agitates the lead soap in benzin, which retains lead oleate in solution, the lead palmitate being deposited. The benzin solution of lead oleate is shaken repeatedly with diluted hydrochloric acid (1 to 7), when lead chloride separates, and a benzin solution of purified oleic acid is left; finally the benzin is driven off by evaporation. The objection to this process is the difficulty of freeing the oleic acid from traces of a disagreeable benzin odor. Ernest C. Saunders (*N. R.*, June, 1880) makes a solution of 5 pounds of white castile soap in 20 pounds of boiling water, adds 10 ounces of sulphuric acid, and boils with stirring, until two clear layers are formed. The upper layer is decanted, shaken with 5 pounds of hot water, and the oily layer again decanted; 4 ounces of lead oxide are dissolved in it with a gentle heat, and while hot 5 pounds of alcohol, previously heated to 65·5° C. (150° F.), are added. It is filtered after standing 24 hours, and 1 ounce of hydrochloric acid shaken with the filtrate; 10 pounds of water are added, the acid decanted, again washed with 10 pounds of water, and finally recovered; the yield is about 2½ pounds. See also process by Charles T. George, 1881 (*A. J. P.*, p. 379). Low grade oleic acids, obtained by the distillation of wool-grease, etc., may contain cholesterin and other unsaponifiable materials from this source (*Allen*). Commercial oleic acid is often adulterated with linoleic acid. Hazura claims to be able to show the presence of one per cent. of this by saponifying the mixture and then adding potassium permanganate. (For details see *A. J. P.*, 1889, p. 356). Grandval and Valser (*Chem. News*, 1890, p. 85) give the following tests for linoleic acid: If a thin layer of the fraudulent oleic acid be placed upon a slip of lead scraped quite clean, and some pure oleic acid be put upon a similar slip of lead for comparison, the next day the impure acid will be more or less resinified, whilst the pure acid will be scarcely altered. If some drops of oleic acid adulterated with linoleic acid be mixed with an equal volume of soda-lye, an intense yellow color will be produced; pure oleic acid, if similarly treated, will merely take a grayish tint.

Properties. "A yellowish or brownish-yellow, oily liquid, having a peculiar, lard-like odor and taste; becoming darker and absorbing oxygen on exposure to air. Specific gravity: about 0·900 at 15° C. (59° F.)." *U. S.* The British Pharmacopœia gives the specific gravity as 0·890 to 0·910. Oleic Acid is "insoluble in water; soluble in alcohol, chloroform, benzol, benzin, oil of turpentine, and fixed and volatile oils. When cooled to about 4° C. (39.2° F.), Oleic Acid becomes semi-solid, and, on further cooling, congeals to a whitish, solid mass. When heated to a temperature of about 95° C. (203° F.), the Acid begins to be decomposed, giving off acrid vapors. At a higher temperature it is completely dissipated. An alcoholic solution of Oleic Acid has a feebly acid reaction upon litmus paper. Equal volumes of Oleic Acid and of alcohol, mixed at the ordinary temperature, should give a clear solution without separating any oily drops upon the surface (absence of *fixed oils*). If 1 Gm. of Oleic Acid be heated with 20 C.c. of alcohol, 2 drops of phenolphtalein test-solution added, and then a strong solution (1 in 4) of sodium hydrate, drop by drop, until the liquid has acquired a permanent red tint and the Acid is saponified; next acetic acid added until the red color of the liquid is just discharged, and the liquid filtered,—10 C.c. of the filtrate mixed with 10 C.c. of ether should not be rendered more than slightly turbid by the addition of 1 C.c. of lead acetate test-solution (absence of notable quantities of *palmitic* and *stearic acids*)." *U. S.*

"At 40° to 41° F. (4·5° to 5° C.) it becomes semi-solid, melting again at 56° to 60° F. (13·3° to 15·5° C.). Dissolve about 1 gramme of the Acid in 15 to 20 times its volume of *alcohol* (90 per cent.); add two drops of *solution of phenol-phthalein* and, drop by drop, a 25 per cent. aqueous solution of *sodium hydroxide* until the liquid after shaking remains slightly red and the acid is completely neutralized; then drop in *diluted acetic acid* until, after shaking, the red tint just disappears; filter the liquid, and mix about 10 cubic centimetres of it with an equal volume of Purified Ether and 1 cubic centimetre of a 10 per cent. aqueous solution of *lead acetate;* only a slight turbidity should result (absence of more than traces of stearic or palmitic acid)." *Br.*

Chemical Constitution. Oleic acid, $C_{18}H_{34}O_2$, does not belong to the "fatty acid" series, but differs from the corresponding acid of that series, stearic acid, $C_{18}H_{36}O_2$, by having two atoms less of hydrogen. It belongs to a series derived by oxidation from alcohols, which, like allyl alcohol, C_3H_5OH, have two atoms of hydrogen less than the normal monatomic alcohols, like propyl alcohol, C_3H_7OH. The alcohol from which oleic acid is in theory derivable is not, however, known. Oleic acid is monobasic, as shown in the formula $HC_{18}H_{33}O_2$.

Medical Properties. Oleic acid is not itself used in medicine, but is official for the preparation of oleates, which act as corresponding ointments, but are more elegant.

ACIDUM PHOSPHORICUM. U. S. Phosphoric Acid.

(ĂC'Ĭ-DŬM PHŌS-PHŎR'Ĭ-CŬM.)

"A liquid composed of not less than 85 per cent., by weight, of absolute Orthophosphoric Acid [$H_3PO_4 = 97·8$], and not more than 15 per cent. of water. The above-mentioned percentage (85) is that assumed for Phosphoric Acid in the formulas of pharmacopœial preparations. Phosphoric Acid should be kept in glass-stoppered bottles." *U. S.*

ACIDUM PHOSPHORICUM CONCENTRATUM. Br. Concentrated Phosphoric Acid.

(ĂC'Ĭ-DŬM PHŌS-PHŎR'Ĭ-CŬM CŌN-CĔN-TRĀ'TŬM.)

"A liquid containing 66·3 per cent. of hydrogen orthophosphate, H_3PO_4, with 33·7 per cent. of water. It may be prepared by treating, with water and nitric acid, the residue left after burning phosphorus in air." *Br.*

The U. S. P. 1890 phosphoric acid is much stronger than that of the U. S. P. 1880; it is now 85 per cent., instead of 50 per cent. The United States Pharmacopœia has very properly abandoned the former official process for this acid; it is more profitably and conveniently made on a large scale, and with such precautions and safeguards as cannot be easily used by the apothecary; the process of the U. S. P. 1880, however, will be found in the foot-note.*

This preparation is recommended on account of its small bulk and its great convenience to the apothecary for preparing the diluted acid. The glacial phosphoric acid is no longer official, it having been shown that it is practically impossible to obtain it of sufficient purity to be reliable. (See *Proc. A. P. A.*, 1875, pp. 666, 672.) The present syrupy acid is a great improvement in every way, as it can be obtained of undoubted purity and strength, and by

* "Phosphorus, *sixteen parts;* Nitric Acid, Distilled Water, each, *a sufficient quantity,* To make *one hundred parts.* Mix *one hundred parts* of Nitric Acid with *one hundred parts* of Distilled Water, in a glass retort having the capacity of *four hundred parts.* Having placed the retort upon a sand-bath or wire-gauze support, connect it loosely with a well-cooled receiver and add to the acid in the retort the Phosphorus previously cut into fine pieces. Insert a funnel through the tubulure of the retort, and then gradually apply heat until the reaction is seen to commence. Regulate the heat carefully so as to prevent the reaction from becoming too violent, or, if necessary, check it by the addition of a little Distilled Water through the funnel. From time to time return the acid liquid, which collects in the receiver, into the retort, until all the Phosphorus is dissolved. Then transfer the liquid to a weighed porcelain capsule, and continue the heat, at a temperature not exceeding 190° C. (374° F.), until the excess of Nitric Acid is driven off, and an odorless syrupy liquid remains. Cool the dish and contents, and add enough Distilled Water to make the liquid weigh *one hundred parts.* Test small portions for Nitric, Phosphorous, and Arsenic Acids by the following methods. If Nitric Acid should be present, evaporate the liquid until no reaction for Nitric Acid can be obtained. Then cool the Acid and add enough Distilled Water to make the product weigh *one hundred parts.* If Phosphorous Acid be present, add to the liquid a mixture of *six parts* of Nitric Acid and *six parts* of Distilled Water, and again evaporate until no reaction for Phosphorous or Nitric Acid can be obtained. Then, having cooled the Acid, add sufficient Distilled Water to make the product weigh *one hundred parts.* If Arsenic Acid be present, dilute the Acid with *one hundred and fifty parts* of Distilled Water, heat to about 70° C. (158° F.), and pass through the liquid a stream of Hydrosulphuric Acid Gas for half an hour, then remove the heat and continue passing the gas until the liquid is cold. Close the vessel tightly, set it aside for 24 hours, filter the liquid, heat it until all the odor of the gas has been driven off, again filter, and evaporate until the residue weighs *one hundred parts.* Preserve the product in glass-stoppered bottles." *U. S.* 1880.

the addition of water diluted phosphoric acid of any desired strength can easily be produced from it.* The process for its preparation is the well-known one of oxidizing phosphorus by the use of nitric acid, the former British method not differing materially from that of the U. S. Pharmacopœia of 1880, except in the absence of the use of hydrogen sulphide for precipitating the arsenical compounds usually found in phosphorus, and in the greater strength of the finished product. The British concentrated phosphoric acid contains 66·3 per cent. of orthophosphoric acid, whilst the U. S. phosphoric acid now contains 85 per cent. Phosphorus is oxidized at the expense of the nitric acid, any excess of nitric acid and all the lower oxides of nitrogen being driven off by heat. Strong nitric acid acts too energetically on phosphorus, producing explosion and rapid combustion; but when diluted, as in the processes above given, it parts with its oxygen slowly, and it is even desirable to aid the operation with a gentle heat. Along with the nitrous fumes, a portion of the undecomposed nitric acid also rises in vapor, which, in the British process, to prevent loss, is collected by means of a distillatory apparatus and returned to the retort. In the U. S. process of 1870 the same result was effected by placing over the liquid in the capsule a glass funnel, upon the inner surface of which the acid was condensed, and returned of itself into the capsule so as considerably to simplify the operation. This modification was originally suggested by Mr. Geo. W. Andrews, of Baltimore, who, however, inverted a dish over the materials; the suggestion of the funnel being due to Prof. Procter. The operation was continued till the whole of the phosphorus was converted into phosphoric acid and dissolved: the liquid having been deprived of any remaining acid, and reduced to a certain weight by concentration, the process was completed by adding a certain measure of water, so that an acid of definite strength was obtained. Prof. Diehl found, in carrying this process into effect, that the glass funnel covering the capsule almost always breaks through the violence of the reaction, thus causing loss of phosphorus, besides annoyance to the operator. He therefore prefers using a French tubulated glass retort, and this suggestion was adopted in the process for Phosphoric Acid (*U. S. P.* 1880). (*A. J. P.*, 1867, p. 138.) Prof. G. F. H. Markoe (*Proc. A. P. A.*, 1875, p. 677) proposed a method for making phosphoric acid which is particularly adapted for making large quantities, yet works well in a smaller way. Into a flask (or stone jar) having double the capacity of the materials used, 12 troyounces of water, 2 troyounces of phosphorus, and 10 grains of iodine are placed, then 40 grains of bromine are cautiously dropped in;† when the reaction has ceased, 12 troyounces of nitric acid are added; a glass funnel is adjusted in the neck of the flask, and a smaller inverted funnel set inside of it; the apparatus is placed in a stoneware dish, and surrounded with cold water or ice; the reaction takes place slowly and regularly. In about 24 hours, if all the phosphorus be not acted upon, heat may be applied until it disappears, and the excess of bromine, iodine, and nitric acid is driven off. The acid may then be diluted to the desired specific gravity. Prof. J. U. Lloyd (*N. R.*, July, 1880) suggests the use of pure alcohol to unite with the nitric acid to form nitrous ether, which is more volatile and thus easier to drive off. Prof. Markoe adds a small quantity of pure oxalic acid, and heats the mixture to 300° F.; at this temperature it is asserted that all the oxalic acid splits into carbon monoxide and carbon dioxide.

Nicolas prepares a pure phosphoric acid by adding a known quantity of pure calcium phosphate gradually to a slight excess of pure dilute hydrofluoric acid contained in a lead or platinum vessel, the mixture being well stirred after each addition. An energetic action takes place. When all the calcium phosphate has been added, the temperature is still maintained for a time to complete the reaction. The calcium fluoride is then filtered off and the solution evaporated. As the solution becomes viscid, the excess of hydrofluoric acid all passes off by evaporation. A syrup containing from 60 to 70 per cent. of phosphoric anhydride can be thus obtained. H. N. Warren suggests a method for preparing phosphoric acid in a pure state, which consists in introducing sodium or other soluble phosphate into a solution of copper sulphate; washing the insoluble copper phosphate formed, and dissolving in solution of phosphoric acid; then electrolyzing the mixture. A pure and very dense copper is said

* James T. Shinn (*A. J. P.*, Oct., 1880) proposes a formula for *Liquor Acidi Phosphorici* and *Liquor Acidi Phosphorici Compositus*. A similar preparation, under the name of Horsford's Acid Phosphates, has a large use in this country. The formula is as follows. *Liquor Acidi Phosphorici* (without Iron): Calcii Phosphat. 384 gr.; Magnesii Phosphat. 256 gr.; Potassii Phosphat. 192 gr.; Acidi Phosphorici (60 per cent.) 640 minims; Aquæ, q. s. ft. 1 pint. *Liquor Acidi Phosphorici Compositus* (with Iron): Calc. Phosphat. 384 gr.; Magnes. Phosphat. 64 gr.; Potassii Phosphat. 32 gr.; Ferri Phosphat. 64 gr.; Acidi Phosphorici (60 per cent.) 816 minims; Aquæ, q. s. ft. 1 pint.

† Dr. W. H. Pile, of Philadelphia, met with a serious accident in preparing diluted phosphoric acid by this process, by adding the bromine too rapidly. (*A. J. P.*, 1875, p. 525.)

to be thrown down, and a large quantity of phosphoric acid of sp. gr. 1·75 is obtained. (*Chem. News*, lxviii. 66.)

Much dissatisfaction has been caused among pharmacists by the fact that diluted phosphoric acid frequently produces a white precipitate in solutions of ferric salts. An examination proved that this occurred when the glacial acid is used, or when high heat had been employed in the concentration. Experiments conducted by Louis Dohme and Prof. Remington seemed to indicate that the precipitation resulted from the presence of pyrophosphoric acid. (*Proc. A. P. A.*, 1874, pp. 431, 511; 1875, pp. 663, 670, 677.) Considerable difficulty was experienced in driving off all the nitric acid, and in the attempt to do so the temperature became so elevated as to reconvert some of the tribasic acid to the bibasic form. This occurred slightly at 148·8° C. (300° F.), but to a much greater extent between 176·6° C. (350° F.) and 204·4° C. (400° F.). The diluted acid, made from phosphorus, can be brought to the boiling-point of 232·2° C. (450° F.), and will then only produce a slight cloud with tincture of ferric chloride, but if diluted, when cool, with about half its bulk of cold water, which causes considerable elevation of temperature, it forms a clear solution. The same acid evaporated, heated to redness, allowed to congeal, and then dissolved in water, precipitated the iron solution. The addition of twenty per cent. of sodium pyrophosphate to the same dilute acid made a preparation which in all respects resembled that made from the glacial acid; thus giving evidence that the presence of this contamination was the cause of the difference in the two preparations.

It has been suggested that red phosphorus might be substituted for common phosphorus, as producing the same results, with less danger of explosion; but the official process, when carefully followed in reference to due dilution and a moderate heat, is not dangerous.

The following is Lyon's table exhibiting the quantity of orthophosphoric acid and phosphoric anhydride contained in solutions of different densities at 15° C. (59° F.).

Specific Gravity 15° C. at 59° F. in air.	Percentage of		Specific Gravity 15° C. at 59° F. in air.	Percentage of		Specific Gravity 15° C. at 59° F. in air.	Percentage of

Properties. "A colorless liquid, without odor, but having a strongly acid taste. Specific gravity, not below 1·710 at 15° C. (59° F.) [1·5 *Br.*] Miscible, in all proportions, with water or alcohol. When heated, the liquid loses water; at 200° C. (392° F.) it gradually begins to change to pyrophosphoric acid. At a still higher temperature it is converted into

metaphosphoric acid, which volatilizes in dense fumes, or forms, on cooling, a transparent mass of glacial Phosphoric Acid. The Acid, even when largely diluted, has an intensely acid reaction upon litmus paper. If a small portion of Phosphoric Acid be supersaturated with ammonia water, the addition of magnesium sulphate test-solution (or of magnesia mixture) produces a white, crystalline precipitate. If this precipitate be dissolved in diluted acetic acid, the solution yields a yellow precipitate with silver nitrate test-solution. If a crystal of ferrous sulphate be dropped into a cooled mixture of 1 C.c., each, of Phosphoric and sulphuric acids, no brown or brownish-black color should appear around the crystal (absence of *nitric acid*). If 1 C.c. of Phosphoric Acid be diluted with 5 C.c. of water, and the liquid gently warmed, it should not be blackened upon the addition of a small amount of silver nitrate test-solution, or rendered turbid by mercuric chloride test-solution (absence of *phosphorous acid*). If 1 C.c. of Phosphoric Acid (in which nitric and phosphorous acids have previously been shown to be absent) be mixed with 1 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), and a small piece of pure tin-foil added, no coloration should appear within one hour (limit of *arsenic*). Upon adding to 1 C.c. of Phosphoric Acid a mixture of 3 C.c. of alcohol and 1 C.c. of ether, no turbidity should appear (absence of *phosphate*). After neutralizing a portion of the Acid with ammonia water, the addition of ammonium sulphide test-solution should produce neither a color nor a precipitate (absence of *iron*, etc.). After diluting a portion of the Acid with 5 volumes of water, no precipitate should be produced, in separate portions of the liquid, by barium chloride test-solution (absence of *sulphuric acid*), or by silver nitrate test-solution (absence of *hydrochloric acid*); nor should any precipitate be formed, even after several hours, by the addition of an equal volume of tincture of ferric chloride (absence of *pyrophosphoric* and *metaphosphoric acids*). 0·978 Gm. of Phosphoric Acid, diluted with water, should require, for neutralization, not less than 17 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 5 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.*

"Evaporated, it leaves a residue which melts at a low red heat, and when cold forms a glass-like mass. The Acid yields, when neutralized, the reactions characteristic of phosphates. Specific gravity 1·5. Each gramme of it mixed with 2·5 grammes of Lead Oxide in fine powder should leave on evaporation a residue which, after it has been heated to dull redness, weighs 2·98 grammes. It should yield, when diluted with *water*, no characteristic reaction with the tests for lead, copper, arsenium, calcium, potassium, sodium, ammonium, chlorides, or nitrates, and only slight traces of iron or sulphates. Diluted, with five or six times its bulk of *water*, it is not precipitated by *solution of albumen* (absence of metaphosphoric acid), nor on adding Tincture of Ferric Chloride and setting the mixture aside for several hours (absence of metaphosphoric and pyrophosphoric acids). Diluted with *water* and the mixture set aside, no precipitate occurs (absence of silica). Diluted and mixed with an equal volume of *test-solution of mercuric chloride* and heated, no precipitate is formed (absence of phosphorous acid)." *Br.*

Medical Properties. This acid is rarely used medicinally. It has the same properties and uses as the diluted Phosphoric Acid (see p. 82). The dose is 2 to 5 minims (0·12–0.3 C.c.), about one-eighth that of the diluted acid.

Acidum Phosphoricum Glaciale. (*Glacial Phosphoric Acid; Metaphosphoric Acid, Monobasic Phosphoric Acid; Monohydrated Phosphoric Acid; Acide phosphorique glacial*, Fr.; *Glasige Phosphorsäure*, G.) Formula HPO_3; mol. wt., 80. Phosphoric oxide consists of two atoms of phosphorus and five atoms of oxygen, P_2O_5, and can be obtained only by the direct union of its constituents, which takes place when phosphorus is burned in perfectly dry oxygen gas. Thus procured, it is in the form of a white amorphous powder, extremely deliquescent, volatilizable at a red heat, and assuming, when it cools after fusion, a vitreous appearance. The classic researches of Prof. Graham first established clearly the character of the several varieties of phosphoric acid, which may be considered as derived from this oxide. When amorphous phosphorus is boiled with nitric acid, or when phosphoric oxide is boiled with water, the oxide takes up three molecules of water, and yields tribasic or *ordinary phosphoric* acid, according to the reaction: $P_2O_5 + 3H_2O = H_6P_2O_8$ or $(H_3PO_4)_2$. If this acid be heated for a considerable time to 215° C. (419° F.), the two molecules lose one molecule of water and yield *pyrophosphoric* acid, a tetrabasic variety, according to the reaction: $H_6P_2O_8 - H_2O = H_4P_2O_7$. Lastly, at a red heat the ordinary phosphoric acid is converted into *metaphosphoric* acid, a monobasic variety, according to the reaction: $H_3PO_4 - H_2O = HPO_3$. This last variety may also be obtained direct from the oxide by dissolving it in cold water, when it takes up one molecule of water:

$P_2O_5 + H_2O = H_2P_2O_6$ or $(HPO_3)_2$. (See *Chem. News*, Jan. 7, 1876; or *A. J. P.*, 1876, p. 109.) An aqueous solution of either of the three acids, heated so long as water escapes, yields the monobasic or metaphosphoric acid; and as, upon cooling, it becomes a transparent ice-like solid, it has received in this state the name of glacial phosphoric acid. Conversely, this monobasic acid is slowly transformed, in aqueous solution, and more rapidly if the solution is heated, into the tribasic form. Prof. Maisch has ascertained that nitric acid, added to the solution of the monobasic acid, with the aid of heat, causes the change from the monobasic to the tribasic form, viz., to the common phosphoric acid, without the intermediate production of the tetrabasic variety.

Tests. The three acids are distinguishable by peculiar reactions. Thus, the *monobasic* is characterized by coagulating albumen, and giving white, gelatinous, uncrystallizable precipitates with the soluble salts of barium, lime, and silver; the *tetrabasic* does not coagulate albumen, and, though it causes a *white* precipitate with silver nitrate, must first be neutralized; the tribasic does not coagulate albumen, and, until neutralized, does not precipitate silver nitrate, but after neutralization throws down a *yellow* precipitate of silver phosphate.

Glacial phosphoric acid is most advantageously obtained from calcined bones, by first treating them with sulphuric acid, which produces an insoluble calcium sulphate and soluble acid phosphate; then dissolving out the latter salt, and saturating it with ammonium carbonate, which generates ammonium phosphate in solution; and, finally, obtaining the ammonium phosphate by evaporation to dryness, and then igniting it in a platinum crucible. The ammonia and all the water except the one molecule needed for the formation of metaphosphoric acid are driven off, and the glacial acid remains.

Properties. Thus procured, glacial phosphoric acid is in the form of a white, uncrystallizable, fusible solid, inodorous, very sour to the taste, slowly deliquescent, slowly soluble in water, and soluble also in alcohol. Its formula is HPO_3, and it is made up of 11·2 per cent. of water in combination with 88·8 per cent. of phosphoric oxide. As already stated, it is characterized by producing white gelatinous precipitates with albumen, and with the soluble salts of lime, barium, and silver; and the precipitate produced with the barium chloride is readily redissolved by an excess of the acid. This is the form of the acid which results when the oxide, produced by burning phosphorus in dry oxygen gas, is introduced into cold water.

Impurities. Glacial phosphoric acid is seldom prepared in this country. That found in commerce is almost all imported, and chiefly from Germany. It is often more or less impure, containing, as shown by the experiments of Prof. Maisch, silica, and calcium and magnesium phosphates, which are precipitated from a neutralized solution of the acid by ammonia. In one instance 8 per cent. of these impurities was found, but in some others little or none. Prof. Maisch never found nitric or hydrochloric acid, and sulphuric acid rarely; and, though the presence of ammonia might be suspected from the source whence the acid is obtained, he did not detect it. (*A. J. P.*, 1860, p. 194.) The chief impurity, however, is soda, as has been pointed out by Brescius, Remington, Dohme, Prescott, and others (see *Proc. A. P. A.*, 1875, 666, 672); the acid has been found to contain occasionally as much as 60 per cent. of sodium metaphosphate, and rarely less than 55 per cent. (*N. R.*, Feb. 1879.) Hodgkin (*P. J. Tr.*, 1891, p. 217) examined eight samples of German and English glacial phosphoric acid, and found in them, respectively, the following proportions of absolute orthophosphoric acid: 92·8, 91·5, 90·8, 85·4, 84·4, 83·8, 80·1, and 78·1 per cent. In consequence of its deliquescence upon exposure to the air, a portion of the monobasic acid passes into the tribasic state. This may be detected, if in considerable quantity, by its giving a yellowish color to the precipitate with silver nitrate. The U. S. P. 1870 directed that the acid, in aqueous solution, should yield no precipitate with hydrogen sulphide, showing the absence of metals; should cause a white precipitate with barium chloride soluble in an excess of acid; with an excess of ammonia should cause only a slight turbidity, proving the almost total absence of earthy salts; and should yield no ammonia when treated with potassa in excess. Should the presence of arsenic be ascertained by the tests for that metal, it may be separated by boiling with hydrochloric acid. so as to convert the arsenic into its very volatile chloride, which would escape with the vapors of the hydrochloric acid.

Glacial phosphoric acid was introduced into the Pharmacopœia of 1860 as affording a convenient method of preparing the medicinal acid, but, owing to its unreliability, was very properly dismissed from the Pharmacopœia. Thirty-eight and a half grains, dissolved in a fluidounce of water, form a solution about equal in strength to the U. S. diluted acid of Pharmacopœia 1860.

ACIDUM PHOSPHORICUM DILUTUM. U. S., Br. Diluted Phosphoric Acid.

(ĂC'Ĭ-DŬM PHŌS-PHŎR'Ĭ-CŬM DĬ-LŪ'TŬM.)

"A liquid containing, by weight, 13·8 parts of hydrogen orthophosphate, H_3PO_4, and 86·2 parts of water." *Br.*

Acide phosphorique médicinal, *Fr.*; Verdünnte Phosphorsäure, *G.*

"Phosphoric Acid, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *seven hundred and fifty grammes* [or 26 ounces av., 199 grains], To make *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]. Mix them. Keep the product in well-stoppered bottles. Diluted Phosphoric Acid contains 10 per cent., by weight, of absolute Orthophosphoric Acid. Specific gravity, about 1·057 at 15° C. (59° F.). It corresponds in properties to Phosphoric Acid (see *Acidum Phosphoricum*), and should conform to the same reactions and tests. 4·89 Gm. of Diluted Phosphoric Acid should require for neutralization 10 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.*

"Concentrated Phosphoric Acid, 3 *fl. ounces* (Imperial measure) or 4·5 *ounces*, or 150 cubic centimetres or 225 grammes; Distilled Water, a sufficient quantity. Dilute the Concentrated Phosphoric Acid with sufficient Distilled Water to form, at 60° F. (15·5° C.), *one pint* (Imp. meas.) or one thousand cubic centimetres of Diluted Phosphoric Acid." *Br.*

It will be observed that in both Pharmacopœias diluted phosphoric acid is made by simple dilution of the stronger acid, and that the older method of dissolving the glacial acid has been, very properly, abandoned. (See *Acidum Phosphoricum Glaciale.*) The official diluted acid is weaker than the British, the U. S. P. acid containing 10 per cent. of orthophosphoric acid, whilst the British contains 10 per cent. of phosphoric anhydride, P_2O_5, which corresponds to about 14 per cent. of orthophosphoric acid. The specific gravity of the British acid is 1·08, and "Each gramme of it mixed with 0·5 gramme of Lead Oxide in fine powder should leave on evaporation a residue which after it has been heated to dull redness weighs 0·6 gramme." *Br.*

Properties. Diluted phosphoric acid is a colorless, inodorous, sour liquid, acting strongly on litmus, and possessing powerful acid properties. Although evaporated so as to become dense, it is not corrosive like the other mineral acids. Dr. Neubauer found that the strong acid, when pure and warm, was capable of dissolving calcium oxalate. The official acid is not precipitated by barium chloride or silver nitrate. If precipitates are produced, barium chloride indicates sulphuric acid or a sulphate; silver nitrate, hydrochloric acid or a chloride. Strips of copper or silver are not affected by the acid, showing the absence of nitric acid; it is not colored by hydrogen sulphide, proving the general absence of metals; and albumen produces no precipitate with it, indicating the non-existence of metaphosphoric acid. If sodium carbonate cause a precipitate, calcium phosphate, or some other phosphate insoluble in water, is probably held in solution. It has been supposed that one-tenth of phosphorous acid would render the diluted acid dangerous to life; but experiments go far to show that this was an erroneous opinion, as half a drachm of that acid given to a dog produced no obvious poisonous effect. (See *A. J. P.*, 1858, p. 359.) Phosphorous acid may be detected by testing the medicinal acid with a solution of corrosive sublimate, which will be converted into calomel if this impurity be present. (Pagels, *Chem. Gaz.*, Jan. 15, 1857.)

Old diluted phosphoric acid is very apt to contain microscopic plants. The presence of traces of hydrochloric acid is said to prevent their formation. (Rother, *Drug. Circ.*, 1886, p. 99; Prof. L. E. Sayre, *Proc. A. P. A.*, 1885; Samuel G. Ade, *Proc. A. P. A.*, 1884.)

Medical Properties and Uses. Diluted phosphoric acid is deemed tonic and refrigerant. It is free from astringency, and is certainly a valuable remedy in many cases of *dyspepsia*. Various properties have been ascribed to it, such as allaying pain and spasm, strengthening the sexual organs, preventing the morbid secretion of bony matter, and correcting phosphatic deposits in the urine. The last two properties are supposed to depend upon its power of dissolving calcium phosphate. It has been recommended in *hysteria*, in *diabetes*, and in *leucorrhœa* when the secreted fluid is thin and acrid; it has also been used with asserted good results in *low fevers*, but probably has no action upon the system other than that upon the digestive organs, although Dr. A. Judson (*Ann. de Thérap.*, 1871 and 1872, p. 152) asserts that in doses of from one to three drachms it acts as a stimulant, increasing the force and frequency of the pulse, and causing headache and cerebral confusion,—effects which may be the result of gastric irritation. The dose is from twenty drops to a teaspoonful (1·25–3·75 C.c.), largely diluted.

ACIDUM SALICYLICUM. U. S., Br. Salicylic Acid.

$HC_7H_5O_3$; 137·67. (ĂÇ'Ị-DŬM SĂL-Ị-ÇŸL'Ị-CŬM.) $HC_7H_5O_3$; 138.

"An organic acid, existing naturally, in combination, in various plants, but most largely prepared synthetically from carbolic acid." *U. S.* "A crystalline acid, $C_6H_4.OH.COOH$, obtained from natural salicylates such as the oils of wintergreen (Gaultheria procumbens, Linn.) and sweet-birch (Betula lenta, Linn.), or by the interaction of sodium carbolate and carbonic anhydride." *Br.*

Ortho-Oxybenzoic Acid, *E.;* Acide salicylique, *Fr.;* Salicylsäure, *G.*

In 1834 salicyl aldehyde (*salicylous acid*) was discovered by Pagenstecher in the flowers of *Spiræa ulmaria.* In 1837, Piria and Ettling found that by oxidizing agents salicyl aldehyde was converted into a new body, salicylic acid, and in 1839, Löwig and Weidmann derived the latter principle directly from the flowers of the *Spiræa ulmaria.* Shortly afterwards Prof. Procter (*A. J. P.*, 1843; Aug. 1875) discovered that the acid could be procured from the oil of wintergreen (*Gaultheria procumbens*), which is now known to contain fully 90 per cent. of methyl salicylate. Methyl salicylate is indeed obtainable by distillation from very many plants, but the probabilities are that it never exists already formed in the plant, but is produced during the process of distillation. (See *Betula lenta*, PART II.) When potassa is added to methyl salicylate, a new salt is formed, from which the acid is readily obtained by means of hydrochloric acid. Notwithstanding the discovery of this fact, and also the invention of still another process of manufacture by Ettling in 1845, salicylic acid remained so expensive as to be of no value in the arts until Kolbe and Lautemann discovered that it could be prepared by uniting phenol with carbonic acid through the instrumentality of sodium. The article now began to attract some attention, but remained beyond the reach of general use until Prof. Kolbe, continuing his researches, succeeded, in 1874 (*Journ. für Prakt. Chemie*, July, 1874), in producing it at a moderate cost.

Preparation. While salicylic acid may be prepared from salicin by fusion with potassium hydrate, or from oil of wintergreen by saponification with potassium hydrate solution, practically it is now obtained, according to Kolbe's patent, by treating sodium phenol (or carbolate) with carbon dioxide gas. For this purpose, the most concentrated caustic soda solution is evaporated with the corresponding amount of phenol to a dry powder, which is then heated to 100° C. (212° F.), while a stream of dry carbon dioxide gas is passed over it. The temperature is gradually raised to 180° C. (356° F.), increased to 220° C. (428° F.) as soon as phenol distils over, and finally raised to 250° C. (482° F.), until no more phenol distils. In the retort, the half of the phenol used remains as sodium salicylate, while the other half has distilled over unchanged. The reaction is as follows: $2C_6H_5ONa + CO_2 = C_6H_5OH + C_6H_4(ONa),COO,Na$.

The sodium salt thus obtained is dissolved in water, decomposed by hydrochloric acid, the salicylic acid filtered off, washed, and crystallized out of hot water, or purified by sublimation in a current of superheated steam. P. W. Hofmann subsequently patented a process whereby distillation with superheated steam, with its attendant loss, is obviated; to the crude solution is added stannous chloride, which precipitates a dark mass containing the impurities, the clear supernatant liquid is then decomposed with hydrochloric acid and the crystals of salicylic acid purified by washing and the use of centrifugals. (*Pharm. Centralh.*, 1892, 412.) An important improvement was subsequently made in Kolbe's process whereby all, instead of only half, of the phenol-sodium is converted into salicylate. R. Schmitt has found (*Wagner's Jahresbericht für Chem. Tech.*, 1885, p. 490) that if dry sodium phenolate and dry carbon dioxide are allowed to act on each other at ordinary temperatures, as long as absorption takes place a phenyl-sodium carbonate, $CO \begin{cases} OC_6H_5 \\ ONa \end{cases}$, is formed. If this is now heated for several hours in a closed vessel to 140° C., a molecular rearrangement takes place, and simple sodium salicylate, $C_6H_4(OH)COONa$, is formed without any separation whatever of phenol. Schmitt's process has been purchased by the owners of Kolbe's patent.* Salicylic acid has also been

* Professor J. U. Lloyd gives the following process for preparing salicylic acid from oil of wintergreen. Pure wintergreen oil, 3 parts; white caustic potash, 3 parts; hydrochloric acid, 8 parts; water, q. s. Dissolve the caustic potassa in two parts of water in a glass or porcelain vessel, and heat to the temperature of 180° F. Stir into this gradually the oil, using a glass or porcelain spatula. Into another vessel place 64 parts of cold distilled water, and add the hydrochloric acid. Then with constant stirring add the solution of the potassium salicylate. The magma of minute crystals of salicylic acid must be separated with a thin muslin strainer (previously moistened) and pressed, then dried by exposure to a temperature of 150°. The yield of this crude acid will be slightly over two parts. Dissolve this in six parts of cold alcohol, and filter through a funnel stopped with cotton. Then with constant stirring pour the filtrate into 32 parts of cold water. The magma of minute crystals must be separated with a thin muslin strainer, and dried by exposure to a heat of 150° F. The yield is a trifle less than 2 parts.

obtained synthetically from copper benzoate and water, which, when heated together in sealed tubes, yield cuprous oxide, free benzoic acid, and salicylic acid. (E. F. Smith, *Am. Chem. Journ.*, 2, p. 338.) Dr. A. Rautert has found that the acid volatilizes with steam of 170° C. (338° F.), and has devised a process of purification based upon this, which yields at very little cost a beautiful product. Biel (*Pharm. Zeitsch. f. Russl.*, 1876) reports that the sublimed acid is liable to decompose spontaneously. Dialyzed salicylic acid of beautiful appearance has been in the market since 1876. All traces of tarry matter can be removed by dialysis, and this acid is unexceptionable. Kolbe also obtained salicylic acid from the barium and calcium carbolates, but the yield was less than when the sodium salt was employed. The potassium phenol yielded only a trace of the salicylic acid, but an abundance of *paraoxybenzoic* acid.

Properties. Salicylic acid, when pure, occurs as a snow-white crystalline powder, free from odor, and also from taste, but leaving a sense of astringency on the tongue and of irritation in the fauces, with an increased flow of saliva. "Light, fine, white, prismatic needles, or a light, white, crystalline powder; odorless, having a sweetish, afterwards acrid taste, and permanent in the air." *U. S.* To the mucous membrane of the nose it is irritating, and it will sometimes produce sneezing. It crystallizes out of its hot aqueous solution on cooling in slender, often very long needles, and on the spontaneous evaporation of its alcoholic solution in large four-sided prisms. It is strongly acid, acting decisively on blue litmus, and forming salts not only with alkalies, but also with metallic oxides. Salicylic acid is "soluble, at 15° C. (59° F.), in about 450 parts of water, and in 2·4 parts of alcohol; in 14 parts of boiling water, and very soluble in boiling alcohol. Also soluble in 2 parts of ether, 2 parts of absolute alcohol, and 80 parts of chloroform. When heated to 156° C. (312·8° F.), the Acid begins to melt, and is completely melted at 157° C. (314·6° F.); at a higher temperature it is gradually dissipated without leaving more than 0·6 per cent. of fixed residue. The saturated, aqueous solution has an acid reaction, and is colored intensely bluish-violet (in high dilution violet-red) by ferric chloride test-solution." *U. S.* "Soluble in 3 parts of *alcohol* (90 per cent.), in 2 of *ether*, or in 200 of *glycerin*. Dissolves in *solutions of ammonium citrate*, *ammonium acetate*, *sodium phosphate*, and in solution of *borax*, also in solutions of alkaline hydroxides and carbonates, salicylates being produced; such solutions of salicylates, if not weaker than 1 per cent., afford a yellowish-brown precipitate with *solution of uranium nitrate* (distinction from carbolates and sulphocarbolates). The crystals melt at 312·8° to 314·6° F. (156° to 157° C.), and below 392° F. (200 C.) volatilize without decomposition. *Test-solution of ferric chloride* gives with the aqueous solution a violet color, or, if the solution be largely diluted, a reddish-violet color." *Br.* When heated rapidly it is converted into carbolic and carbonic acids. It is stated that, by careful heating, glycerin can be made to dissolve 1 part in 50, and that the solution not only remains clear on cooling, but also may be diluted with water without separating. (*A. J. P.*, 1875, p. 212.) Dr. Goldsborough affirms that a mixture of the acid with alcohol, 1 to 10, may be diluted with 150 parts of water without crystallizing. By the presence of various neutral salts its solubility is increased without its antiseptic value being interfered with. Thus:

Mixed with 1	part	potassium nitrate,	it dissolves in	50	parts	cold	water.
"	"	1½	parts	ammonium citrate,	"	60	"	"	"
"	"	2	"	sodium sulphite,	"	50	"	"	"
"	"	2	"	sodium phosphate,	"	50	"	"	"
"	"	2½	"	sodium phosphate,	"	12½	"	"	"

(Allen, *Commerc. Org. Analysis*, 1879, p. 344; see, also, R. Rother, *A. J. P.*, 1886, p. 420.)

On distilling salicylic acid or one of its salts with wood-spirit and sulphuric acid, acid methyl salicylate is formed, having an agreeable aromatic odor. The reaction with ferric salts is much more delicate (1 in 100,000) than that of phenol with the same reagent (1 in 3000). Commercial salicylic acid is often very impure. Sodium chloride, carbolic acid, cresotic acid, and oxybenzoic and para-oxybenzoic acids are the usual impurities. The first of these substances remains on igniting the acid. Carbolic acid may be detected by nearly neutralizing the sample with soda and agitating the liquid with ether. On evaporating, the ethereal liquid leaves the carbolic acid recognizable by its smell and taste. (Allen, *Commerc. Org. Anal.*, p. 347.)

The most sensitive test for it is a ferric salt, with which it develops a beautiful violet color. Goldsborough states that to insure the delicacy of this reaction it is necessary that the iron salt be perfectly neutral; also that with this precaution he has clearly detected 1 part of the acid in 400,000 parts of water. On the addition of ammonia the violet color is changed to a reddish brown, then to an orange, then to a permanent greenish yellow. Sulphuric and nitric

acids change the violet to a light brown (*Goldsborough*). It must be remembered that salicylous acid reacts similarly with ferric salts. Salicylous acid, however, precipitates the silver potassio- or ammonio-nitrate white, the salicylic acid yellow. Dr. A. Fagans (*A. J. P.*, 1893, p. 133) points out that salicylic acid cannot be colorimetrically estimated in aqueous solutions in presence of phenols, but that in alcoholic solution only the former reacts with ferric chloride. Kolbe recommends a simple test to detect impurities. A little of the acid is dissolved in 10 times its weight of strong alcohol, and the solution allowed to evaporate spontaneously from a watch crystal. If the salicylic acid which remains in the dish be perfectly colorless, the acid is strictly pure; it should not be of a brown color, although a slight yellowish color would not indicate sufficient impurity to affect its medicinal value. Hager states that pure salicylic acid equal in volume to the size of a bean produced, after agitation with about 5 C.c. of pure sulphuric acid, a colorless solution, while others which yielded a white residue from the alcoholic solution produced yellowish to brown-yellow solutions. (*A. J. P.*, June, 1877.)

By distilling with alcohol and strong sulphuric acid, salicylic acid forms methyl- and ethyl-salicylic acids.

Tests. "On adding to a small portion of Salicylic Acid, in a test-tube, about 1 C.c. of concentrated sulphuric acid, then, cautiously, about 1 C.c. of methylic alcohol, in drops, and heating the mixture to boiling, the odor of methyl salicylate will be evolved. On allowing a saturated, alcoholic solution of the Acid to evaporate spontaneously in a glass or porcelain capsule, in a place protected from dust, a perfectly white, crystalline residue should remain (absence of *iron*, *carbolic acid*, or *coloring matter*). If 1 Gm. of the Acid be dissolved in an excess of cold sodium carbonate test-solution, the liquid agitated with an equal volume of ether, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, should be free from the odor of *carbolic acid*. On treating about 0·5 Gm. of the Acid, in a clean test-tube, with 10 C.c. of concentrated sulphuric acid, no color should be imparted to the latter within fifteen minutes (absence of *readily carbonizable, organic impurities*). A solution of 0·5 Gm. of the Acid in 10 C.c. of alcohol, mixed with a few drops of nitric acid, should remain unaffected upon the addition of a few drops of silver nitrate test-solution (absence of *hydrochloric acid*)." *U. S.* "Shaken up with a small proportion of *water*, the mixture filtered, and the solution evaporated, there remains a white residue, having no buff-tinted fringe (absence of iron, organic impurities, and coloring matter). Salicylic Acid dissolves in cold *sulphuric acid*, imparting to the liquid no color in 15 minutes (absence of organic impurities). When 1 gramme of the Acid is dissolved in an excess of cold *solution of sodium carbonate*, the liquid agitated with an equal volume of *ether*, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, should be free from the odor of phenol (absence of phenol)." *Br.* Traces of salol are found in salicylic acid. (Hoffmann, *Proc. A. P. A.*, 1896, 232.)

Medical Properties and Uses. Salicylic acid was originally brought to the notice of the profession on account of its inhibitory influence on *putrefaction*. Kolbe found that 0·04 per cent. had great influence in preventing souring of milk. Bucholz found that 0·15 per cent. of the acid is sufficient to prevent the development of bacteria in ordinary organic mixtures, and that the influence of 0·005 per cent. is plainly visible; 0·3 to 0·4 per cent. of the acid killed bacteria in vigorous growth. (*Arch. Exper. Path. u. Pharm.*, Bd. iv.) The sodium salicylate was about equal to the pure acid, 0·4 per cent. destroying the bacteria. In the preservation of urine, Meyer and Kolbe found that one part of salicylic acid to two thousand of urine was sufficient to prevent putrefaction. (*Journ. für Prakt. Chem.*, Bd. xii.) According to Kolbe and others, salicylic acid arrests or prevents the action of the non-organized organic ferments. Thus, it will prevent the development of the hydrocyanic acid by the action of emulsin upon amygdalin in the presence of water, and will also inhibit the formation of the volatile oil of mustard. Dr. Miller found that one per cent. of salicylic acid was sufficient to check the action of ptyaline upon starch, thus equalling in power ten per cent. of carbolic acid. He also found that 0·2 per cent. of salicylic acid distinctly affected outside of the body the digestive action of pepsin. The test of clinical experience has shown that salicylic acid is capable of accomplishing much in antiseptic surgery; but, in spite of certain advantages which the remedy has, it has failed to maintain itself against carbolic acid and other more recent drugs of the antiseptics, so that it is at present but little used by the surgeon. Nevertheless, as it is still employed to some extent, we give the following methods of use.

Thiersch's *salicylic acid wadding* for hermetically sealing wounds is made by dissolving two ounces of the acid in two pints of alcohol (sp. gr. 0·83), diluting with twenty pints of water at from 158° to 178° F., saturating with this six pounds and eight ounces of cotton batting deprived

of oily matter, and afterwards drying. This wadding contains 3 per cent. of the acid; for some purposes a stronger batting, containing 10 per cent., is prepared. When the wound or abscess is discharging profusely, jute is substituted for the cotton batting, because it is much more permeable to pus. An efficient ointment may be prepared by dissolving one and a half parts of the acid in two parts of alcohol and adding lard, or the solubility of the drug in glycerin may be taken advantage of. The following solutions are used in St. Bartholomew's Hospital. Sodium phosphate three parts; salicylic acid one part; water fifty parts.—Salicylic acid one part; olive oil forty-nine parts.—Salicylic acid one part; sodium bicarbonate half part; water one hundred parts.—Salicylic acid ten parts; borax eighteen parts; water one hundred parts. A 25-per-cent. solution, which will bear dilution with water or alcohol, may be prepared according to the following formula. ℞ Acid. salicyl. ʒii; Sodii biborat. ʒi; Glycerini q. s. Mix the acid and borax with four fluidrachms of glycerin; heat gently until dissolved; then add enough glycerin to make one fluidounce.* Prof. Thiersch has found that the drug cannot be employed for cleaning surgical instruments, because it corrodes the steel.

When salicylic acid is given to man in doses just sufficient to manifest its presence, symptoms closely resembling those of cinchonism result. These are fulness of the head, with roaring and buzzing in the ears. After larger doses, to these symptoms are added distress in the head, or positive headache, disturbances of hearing and vision (deafness, amblyopia, partial blindness), and excessive sweating. In some cases there is a decided fall of temperature without alteration of the pulse; but probably more commonly the bodily temperature remains unaltered. The actions upon the system of the acid and of its sodium, ammonium, potassium, and methyl (oil of gaultheria) salts appear to be identical, and, as several cases of poisoning with one or other of these agents have occurred, we are able to trace the toxic manifestations. Along with an intensification of the symptoms already mentioned, there are ptosis, deafness, strabismus, mydriasis, disturbance of respiration, excessive restlessness passing into delirium, slow laboring pulse, olive-green urine, and involuntary evacuations. In some cases the temperature has remained about normal, but in others has approached that of collapse. The respiration seems to be characteristic, it being both quickened and deepened, often sighing. Sweating usually is very free, and the urine early becomes albuminous. Various local evidences of vaso-motor weakness may supervene, such as rapidly appearing bed-sores at points subjected to pressure, and transitory dark-colored maculæ on various parts of the body. In several cases death was probably produced by the acid, although there is scarcely one instance which is beyond doubt. In certain cases the mental disturbance has been strangely prolonged, lasting for eight days. In some instances it is cheerful, in others melancholic in type. It is stated that upon drunkards the acid acts very unfavorably, violent delirium being an early symptom.

Upon the lower mammals salicylic acid acts very much as it does upon man, causing mydriasis, marked disturbance of respiration, great nervous prostration, delirium, dyspnœa, and, if the dose has been large enough, *death by respiratory paralysis.* Moderate therapeutic doses appear to have no powerful influence upon the circulation, such physiological evidence as we have indicating that they increase arterial pressure somewhat by exciting the vaso-motor centre and directly increasing the cardiac force. In overdoses salicylic acid causes fall of the arterial pressure, partly by a direct action upon the heart. Our knowledge of the action of the acid upon the nervous system is very imperfect, but it seems to be a depressant of the motor centres. Moderate doses increase the frequency of the respiration, probably in part by an action upon the peripheral pneumogastrics, but chiefly by a direct influence upon the respiratory centres. Toxic doses paralyze the respiratory centres. The action of salicylic acid upon the temperature of normal man is slight and inconstant, unless toxic doses be given; in fever its antipyretic influence is pronounced, but we have no exact knowledge as to the method of its action. It is absorbed and circulates in the blood probably as sodium salicylate, and is eliminated partly unchanged as a salicylate and partly as salicyluric acid, the green discoloration of the urine being due to indican, or perhaps to pyrocatechin, which may be an educt from the acid. The elimination both of urea and uric acid is increased by the salicylates, which appear in some way to profoundly affect the general protoplasmic chemical activities. When given in very large doses the salicylates irritate the kidneys.

The first effect of a single antipyretic dose in fever is usually a profuse sweat, which may

* *Mixture of Salicylic Acid and Iron* is largely used in hospital practice. The following is the formula of the New York Hospital. Salicylic acid, 20 gr.; pyrophosphate of iron, 5 gr.; phosphate of sodium, 50 gr.; water, sufficient to make 1½ fluidounces. Filter. (*Pharm. Rec.*, 1886, p. 115.)

appear fifteen minutes after the ingestion of the remedy. Very shortly after this the temperature begins to fall, the depression reaching its maximum in from five to six hours. The sweating is profuse and exhausting, amounting, according to Ewald, not rarely to seven hundred and fifty grammes. The perspiration cannot be the chief factor in the reduction of temperature, as there appears to be no relation between its amount and the degree of the fall, and it usually ceases before the latter reaches its maximum. The antipyretic dose employed varies somewhat. Ewald gives as a minimum to the adult seventy-five grains, repeated in five hours if necessary; Justi, from ninety to one hundred and twenty-five grains. The question as to whether good is achieved in fevers by its administration is, of course, entirely separate from that as to its power of reducing temperature. It is certainly possible for a drug to lower the fever-heat and yet to do far more harm than good, and the evidence at hand appears to show that in *typhoid* and other allied febrile affections salicylic acid is not an eligible remedy. It is, indeed, no longer used, having been replaced by antipyrin. The possession of very marked antiperiodic powers has been claimed for salicylic acid, but experience has not substantiated this claim. In *rheumatism* the remedy is the most valuable one known. Although some cases do not seem to yield to the drug, in the great majority of instances improvement sets in within twenty-four hours, and is rapidly followed by disappearance of the pain and fever. The dangers of cardiac and cerebral complications are certainly lessened, but not altogether done away with. In excessive *rheumatic hyperpyrexia* it cannot be depended upon to the exclusion of the cold bath. In chronic *rheumatism* and in *gout*, indeed in all the various forms of the uric acid diathesis, salicylic acid is an extremely valuable remedy, in many cases bringing relief when all other known remedies fail. To gouty patients it is often administered with great advantage in combination with preparations of colchicum. In all of these cases, however, salicylic acid must be considered as essentially palliative rather than curative. Most of the symptoms of gouty or rheumatic affections are due to an excess of uric acid, locally deposited or circulating in the blood or other fluids of the system. The salicylates bring relief by causing the elimination of this accumulated uric acid, but, so far as we know, they do not in any way affect the fundamental lesions or conditions which cause the excessive production of uric acid. The dose of salicylic acid in acute rheumatism may be set down as a drachm (3·88 Gm.) in the twenty-four hours, although it is employed by some practitioners in much larger doses. It may be given in powder, but is best administered in the form of ammonium or sodium salicylate (fifteen grains (0·971 Gm.) five times in twenty-four hours), which are equally efficacious and much less irritant to the stomach than is the acid. If ringing in the ears or other evidences of intoxication appear, the remedy should at once be partially or entirely withdrawn.

Although Kolbe took fifteen grains of salicylic acid daily for nine months without sensible effect, and Lehmann (*Archiv f. Hygiene*, v.) carried similar experiments even to a greater length with similar results, yet the practice of using salicylic acid for a preservative of beer and of articles of food is to be condemned. A commission appointed by the French government reported that the prolonged use even of very small amounts of salicylic acid is dangerous, especially to very aged persons.*

ACIDUM STEARICUM. U.S. Stearic Acid.

$HC_{18}H_{35}O_2$; 283·38. (ĂS′Ĭ-DŬM STĒ-ĂR′Ĭ-CŬM.) $HC_{18}H_{35}O_2$; 284.

"An organic acid, in its commercial, more or less impure form, usually obtained from the more solid fats, chiefly tallow." *U. S.*

This acid has been introduced into the Pharmacopœia of 1890 solely because of its use in making glycerin suppositories. It is officially described as "a hard, white, somewhat glossy solid, odorless and tasteless, and permanent in the air. Insoluble in water; soluble in about 45 parts of alcohol at 15° C. (59° F.); readily soluble in boiling alcohol, and in ether. Stearic Acid, when pure, melts at 69·2° C. (156·6° F.). The commercial acid should have a melting

* The question of the comparative medical value of the artificial and the natural salicylic acid is one of great practical importance. It is seemingly established that the commercial artificial acid is distinctly more poisonous than the natural acid. According to the researches of Prof. Dunstan, the poisonous properties of the artificial acid are due to the presence of three impurities,—namely, meta-, ortho-, and para-cresotic acid, of which acid the ortho- and para- are centric poisons. (See Part II.) Salicylic acid produced from synthetic carbolic acid does not contain these poisons. According to the researches of M. Charteris, any artificial salicylic acid which does not closely resemble in crystalline forms the natural acid, and also have a melting point of almost 157° C., should be rejected as probably poisonous.

point not lower than 56° C. (132.8° F.), and the melted acid should not become opaque and begin to congeal at a temperature lower than 54° C. (129·2° F.). If 1 Gm. of Stearic Acid and 1 Gm. of sodium carbonate be boiled with 30 C.c. of water, in a capacious flask, the resulting solution, while hot, should not be more than opalescent (limit of *undecomposed fat*)."

Medical Properties. Stearic acid probably has no general action upon man.

ACIDUM SULPHURICUM. U. S., Br. Sulphuric Acid.

H_2SO_4; 97·82. (ĂṢ'Ị-DŬM SŬL-PHŪ'RỊ-CŬM.) H_2SO_4; 98.

"A liquid composed of not less than 92·5 per cent., by weight, of absolute Sulphuric Acid [$H_2SO_4 = 97·82$], and not more than 7·5 per cent. of water. The above-named percentage (92·5) is that assumed for Sulphuric Acid in the formulas of pharmacopœial preparations. Sulphuric Acid should be kept in glass-stoppered bottles." *U. S.* "An acid produced by the combustion of sulphur or pyrites and the oxidation and hydration of the resulting sulphurous anhydride by means of nitrous and aqueous vapors. It should contain about 98 per cent. by weight of hydrogen sulphate, H_2SO_4." *Br.*

Acidum Sulfuricum, *P.G.;* Oil of Vitriol, Vitriolic Acid; Acide sulfurique, Huile de Vitriol, *Fr.;* Vitriolöl, Schwefelsäure, *G.;* Acido solforico, *It.;* Acido sulfurico, *Sp.*

Preparation. Sulphuric acid is obtained by burning sulphur or iron pyrites, FeS_2, and allowing the product of combustion, SO_2, to mix with nitrous fumes obtained from the decomposition of nitre, which change SO_2 into SO_3, and this uniting with steam yields H_2SO_4. If the sulphur were burned by itself, the product would be sulphurous oxide, which contains only two-thirds as much oxygen as sulphuric oxide. The object of the nitre is to furnish, by its decomposition, the requisite additional quantity of oxygen. To understand the process, it is necessary to remember that several of the oxides of nitrogen have oxidizing power. Thus, the main reactions of the sulphuric acid process are universally conceded to be $2SO_2 + N_2O_4 = 2SO_3 + N_2O_2$, $SO_3 + H_2O = H_2SO_4$, $N_2O_2 + O_2 = N_2O_4$; in which the sulphurous oxide from the burning pyrites or sulphur is oxidized to sulphuric oxide by the nitrogen tetroxide, which readily parts with two atoms of oxygen to such bodies as sulphurous oxide, and then takes two atoms of oxygen again from the atmosphere, regenerating the original tetroxide. The nitrogen tetroxide thus acts simply as a carrier of atmospheric oxygen, whereby the SO_2 is changed into SO_3. This latter compound then unites with steam to form H_2SO_4, the final product. If the supply of steam be insufficient, at the same time white crystals (*lead chamber crystals*) will form, which have the composition $HSO_3(NO_2)$, and whose formation is explained by the following reactions: $2SO_2 + H_2O + N_2O_3 + O_2 = 2HSO_3(NO_2)$; when steam enters in larger amount they disappear, with formation of sulphuric acid, while red fumes are given off, thus: $2HSO_3(NO_2) + H_2O = 2H_2SO_4 + N_2O_3$. In this case, therefore, nitrous oxide, N_2O_3, assists in the oxidation.

Preparation on the Large Scale. The manufacture of this most important chemical has grown to enormous proportions. In England, where it is very largely manufactured, the present annual production is over 1,000,000 tons, six-sevenths of which are from Spanish pyrites and one-seventh from crude sulphur (*Lunge*). In this country Sicilian sulphur is mainly used, although American pyrites, which is practically free from arsenic, is being employed in increasing amount. The American production of sulphuric acid for the year 1896 was 1,019,501 short tons, valued at $17,331,517, and in 1897 1,128,741 tons, valued at $21,446,079. The production of Germany for 1896 was 577,942 metric tons, valued at $3,536,455. Of the American production in 1897, 591,401 tons were made from pyrites, and the balance from native sulphur. As carried out in England, the process is as follows. Beginning with the pyrites-kilns, or burners, the broken mineral is placed in moderate-sized lumps on the bars of the burners, which have previously been heated to redness, and when the burning is once started, the fire is kept up by placing a new charge on the top of that nearly burned out. The ordinary charge for each burner of pyrites, containing about 48 per cent. of sulphur, is from 5 to 6 cwt., which is burnt out in twenty-four hours. The hot sulphur dioxide and air are drawn from the pyrites-burners through the whole system of tubes, towers, and chambers by help of the powerful draught from a large chimney which is placed in connection with the apparatus. These gases then pass either into a tall tower (called the Glover or denitrating tower), where they meet a descending stream of strong sulphuric acid charged with nitrous fumes, which at this moment of descent is mixed with a weaker sulphuric acid, thereby liberating the nitrous fumes, and these then mix with the sulphur dioxide and air, or they are charged with nitrous fumes direct from the nitre-pots, where a mixture of Chili saltpetre and sulphuric acid liber-

ates them. The mixed gases are then delivered at a temperature of about 75° C. (167° F.) into the first of the leaden chambers. These chambers, of which there are three, are now made of much larger size than was formerly the case, having often a capacity of 38,000 cubic feet. Here the gases meet jets of steam and deposit liquid sulphuric acid, as also in the second chamber. In the third or exhaust chamber all the sulphur dioxide should have been converted into sulphuric acid, and red nitrous fumes must always be visible. These must not be lost, but are drawn into a so-called Gay-Lussac tower filled with coke, over which a finely-divided shower of strong acid is allowed to fall. The nitrous fumes are absorbed by this, and give the so-called nitrated acid used as before mentioned in the Glover tower. The acid obtained in the leaden chamber has a sp. gr. of 1·55, or contains 64 per cent. of H_2SO_4. The acid which comes from the Glover tower (or, in case this is not used, is obtained by further concentration of chamber acid in leaden pans) has a sp. gr. of 1·71, and contains 78 per cent. H_2SO_4. The strongest acid must be procured by still further concentration in glass or platinum vessels, and will contain 98 per cent. H_2SO_4. (Roscoe and Schorlemmer, *Chem.*, vol. i. pp. 321–338.) Within recent years it has been found that to continue the concentration to the limit of 98 per cent. acid in platinum vessels is very destructive to these. Therefore it has been proposed, after a strength of 65° B. or about 90 per cent. acid has been reached, to finish in vessels of cast iron. It is found that the concentrated acid does not attack this, and therefore it can be substituted for platinum to advantage.

According to theory, 100 parts of sulphur burnt should yield 305·9 parts of pure sulphuric acid. In practice the yield is 290–294. The amount of sodium nitrate used varies very much. Manufacturers who employ Glover and Gay-Lussac towers require from 3·5 to 6·5 parts of nitrate for every 100 of sulphur burnt, while works unprovided with these appliances may take from 12 to 13 parts. (*Roscoe and Schorlemmer*, vol. i. p. 337.)

The only way to obtain pure sulphuric acid is by distillation. Owing to the high boiling point of this acid, the operation is rather precarious, in consequence of the danger of the fracture of the retort from the sudden concussions to which the boiling acid gives rise. Dr. Ure recommends that a retort of the capacity of from two to four quarts be used in distilling a pint of acid. This is connected, by means of a wide glass tube three or four feet long, with a receiver surrounded with cold water. All the vessels must be perfectly clean, and no luting employed. The retort is then gradually heated by a small furnace of charcoal, or, what is better, by means of a sand-bath, the retort being buried in the sand up to the neck. It is useful to put into the retort a few sharp-pointed pieces of glass, slips of platinum foil, or clay tobacco-pipe tubes, with the view of diminishing the shocks produced by the acid vapor. The distilled product ought not to be collected until a dense grayish-white vapor is generated, the appearance of which is a sign that the pure concentrated acid is coming over. If this vapor should not immediately appear, it shows that the acid subjected to distillation is not of full strength; and the distilled product, until this point is attained, will be an acid water. In the distillation of sulphuric acid, M. Lembert uses, instead of pieces of glass or platinum foil, fragments of the mineral called quartzite; these after a time get worn and must be changed.

What is said above relates to the mode of preparing common sulphuric acid; but there is another kind, known on the continent of Europe by the name of the *fuming sulphuric acid of Nordhausen*, so called from its properties, and a place in Saxony where it is largely manufactured. This acid is obtained by distilling dried sulphate of iron in large stoneware retorts, heated to redness, and connected with receivers of glass or stoneware. The fuming acid distils over, and ferric oxide is left in the form of *colcothar* or *polishing rouge*, a material used for polishing metals, particularly gold and silver. The formula usually given to this product is $H_2S_2O_7$ or $H_2SO_4 + SO_3$. This would demand about 45 per cent. of sulphuric oxide or SO_3. In fact, the so-called Nordhausen acid seldom contains more than 10 per cent. of SO_3, and to obtain that demanded by the formula a re-distillation is necessary. This product is semi-solid, and is now obtainable in commerce put up in sealed glass flasks. Its sale has been largely curtailed lately, owing to the introduction into commerce of the *anhydride* under the name of *Solid Sulphuric Acid*. When moisture is rigidly excluded, the acid has little action on metals, and it is put up in soldered boxes of tinned sheet-iron; it is used largely in the arts in the manufacture of artificial alizarin. *Persulphuric acid* and the *persulphates* are among the newest products of electrolysis. The ammonium persulphate, $(NH_4)_2S_2O_8$, and potassium persulphate, $K_2S_2O_8$, both form white crystalline salts. The former has already found a considerable technical application as an energetic oxidizing agent in connection with the manufacture of organic dyestuffs and the cyanide extraction of gold.

Properties. Sulphuric acid (*hydrogen sulphate*), commonly called *oil of vitriol*, is a dense, colorless, inodorous liquid, of an oily appearance, and strongly corrosive. On living tissues it acts as a powerful caustic. It unites with water in all proportions, and much heat is evolved on the mixture of the two fluids. When pure, and as highly concentrated as possible, as manufactured in leaden chambers, its sp. gr. is 1·840 (1·8485, Ure), a fluidounce weighing a small fraction over 14 drachms. If its density exceed this, the presence of lead sulphate or other impurity may be inferred. Kohlrausch (*Pogg. Ann. Erganzungs*, Bd. viii. p. 675, Lunge) found the sp. gr. of *pure sulphuric acid*, *real hydrate*, to be 1·8342, and believes that a higher sp. gr. than this is due to impurities (probably lead sulphate). The commercial acid is seldom of this strength. According to Mr. Phillips, it has generally the sp. gr. 1·8433, and this is about the strength of the Br. acid, of which the sp. gr. is stated to be 1·843. The sp. gr. of the official acid is 1·835. Mendelejeff, after a careful determination, found that pure monohydrated sulphuric acid had the specific gravity 1·8371 at 15° C. (59° F.) compared with water at its maximum density, 4° C. (*Amer. Drug.*, 1885, p. 16.) The strong acid boils at 338° C. (640·4° F.), and freezes at —26° C. (—15° F.). When diluted, its boiling point is lowered. When of the sp. gr. 1·78, it deposits crystals of the formula $H_2SO_4 + H_2O$ at about 0° C. (32° F.), and hence it is hazardous for manufacturers to keep an acid of that strength in glass vessels in cold weather, as they are liable to burst. With salifiable bases it forms a numerous class of salts, called sulphates. It acts powerfully on organic bodies, whether vegetable or animal, depriving them of the elements of water, developing charcoal, and turning them black. A small piece of cork or wood dropped into the acid will for this reason render it of a dark color. It absorbs water with avidity, and is used as a desiccating agent. It has been ascertained by Professors W. B. and R. E. Rogers to be capable of absorbing 94 per cent. of carbonic acid gas, a fact having an important bearing on analytical operations. When diluted with distilled water, it ought to remain limpid; and, when heated sufficiently in a platinum spoon, the fixed residue should not exceed one part in 400 of the acid employed. When present in small quantity in solution, it is detected unerringly by barium chloride, which causes a precipitate of barium sulphate. The most usual impurities in it are arsenous acid and lead sulphate; the former derived from the presence of arsenides in the pyrites, where that has been used in the production of the sulphurous oxide; the latter from the leaden boilers in which the acid is concentrated. Sodium or magnesium sulphate is said to have been added to increase its specific gravity. "If Sulphuric Acid be dropped upon sugar or wood, it blackens them. Diluted with 5 volumes of water, it yields, with barium chloride test-solution, a white precipitate, insoluble in hydrochloric acid." *U. S.* Occasionally nitre is added to render dark samples of acid colorless. This addition gives rise to the impurity of potassium sulphate. These impurities often amount to 3 or 4 per cent. The commercial acid cannot be expected to be absolutely pure; but when properly manufactured it should not contain more than one-fourth of 1 per cent. of impurity. The fixed impurities are discoverable by evaporating a portion of the acid, when they will remain. If lead sulphate be present, the acid will become turbid on dilution with an equal bulk of water. This impurity is not detected by hydrogen sulphide unless the sulphuric acid be saturated with an alkali. If only a scanty muddiness arise, the acid is of good commercial quality.

Other impurities occur in the commercial sulphuric acid. The several oxides of nitrogen are always present in greater or less amount. They may be detected by gently pouring a solution of ferrous sulphate over the commercial acid in a tube, when the solution, at the line of contact, will acquire a deep red color, due to the liberation of nitrogen tetroxide. Another method is to pass into tincture of guaiac the gases proceeding from the suspected acid heated with iron filings. If nitrogen tetroxide be present, the tincture becomes blue. The commercial acid, however, is not to be rejected unless the test shows the presence of nitrogen tetroxide in unusual quantity. Nitrogen tetroxide is an injurious impurity when the sulphuric acid is employed in the manufacture of hydrochloric acid, which is decomposed by the nitrogen tetroxide with evolution of chlorine. To remove this impurity it was recommended by Wackenroder, before distilling it, to heat the acid with a little sugar. This and the N_2O_4 mutually decompose each other, and the products are dissipated by heat. For the removal of the nitrogen acids generally, Dr. J. Löwe recommends the addition to the heated sulphuric acid of small portions of dry oxalic acid, so long as it exhibits a yellow tinge. The oxalic acid is decomposed into carbonic acid and oxide, the latter of which, in becoming carbonic acid, deoxidizes and destroys the nitrogen acids. A slight excess of oxalic acid produces no harm, as it is immediately decomposed. Perhaps a better method of getting rid of these acids is to distil

with a little ammonium sulphate. Potassium sulphate, fraudulently introduced into the acid to increase its density, may be detected by saturating the acid with ammonia and heating to redness in a crucible, when ammonium sulphate will be expelled, and the potassium sulphate left.

Arsenic is sometimes present in sulphuric acid. In consequence of the high price of Sicilian sulphur, most English manufacturers have employed iron pyrites for the purpose of furnishing the necessary sulphurous acid in the manufacture of oil of vitriol. As the pyrites usually contains arsenic, it happens that the sulphurous acid fumes are accompanied by arsenous oxide, and thus the sulphuric acid becomes contaminated. From 22 to 35 grains of arsenous acid have been found in 20 fluidounces of oil of vitriol, of English manufacture, by Dr. G. O. Rees and Mr. Watson, and a still larger proportion by Mr. J. Cameron, of South Wales. To detect this impurity, the acid, previously diluted with five or six measures of distilled water, must be examined by Marsh's test. (See *Acidum Arsenosum.*) But a more easy method, said to be nearly as delicate, is that of Bettendorff. A little stannous chloride is treated, in a shallow dish, with pure hydrochloric acid (sp. gr. 1·12) until dissolved. The suspected sulphuric acid is then added, drop by drop, to the solution, the vessel being shaken on each addition. Considerable heat will be produced, and the liquid, if no arsenic be present, will remain clear; but if the acid be in the slightest degree contaminated with the poison, first a yellow, then a brown, and finally a dark grayish brown color will appear, and the liquid become turbid. (*N. R.*, April, 1873, p. 367.) To separate the arsenous acid, Dr. J. Löwe recommends that the concentrated sulphuric acid should be gently heated in a flat dish, in a place where the fumes may be carried off, and then treated with small quantities of finely powdered sodium chloride, constantly stirred in with a glass rod. By the reaction between the arsenous acid and disengaged hydrochloric acid arsenic terchloride is formed, which, being volatile, is separated by the heat. The heat is afterwards continued, to expel the excess of hydrochloric acid. This mode of purification introduces into the oil of vitriol a little sodium sulphate. Buchner proposes a similar process; instead of sodium chloride employing hydrochloric acid, or a stream of the acid gas. This plan does not introduce sodium sulphate into the acid, but is less convenient than that of Löwe, and, when the aqueous hydrochloric acid is used, tends to weaken the oil of vitriol by introducing water. Experience, however, has shown that neither plan can be entirely relied on. An excess of sulphuric acid is said to prevent the formation of the arsenic chloride. (See *A. J. P.*, 1860, p. 88.) For other methods of detecting arsenic in sulphuric acid, see *N. R.*, 1876, p. 297; 1880, p. 101. Until within recent years all the sulphuric acid produced in the United States was made from sulphur. At the present time (1893) nearly half of the sulphuric acid works are using pyrites. Most of the American pyrites ore is entirely free from arsenic. Dupasquier states that tin is sometimes present in commercial sulphuric acid, derived from the solderings of the leaden chambers; but this could scarcely happen now, as care is taken to avoid soldering, and to effect the union of the metal by fusion by means of the blow-pipe. It may be discovered by hydrogen sulphide, which precipitates sulphide of tin, convertible by nitric acid into the white insoluble stannic oxide. Should the precipitate be the mixed sulphides of arsenic and tin, the former would be converted by nitric acid into arsenic acid and dissolved, and the latter into insoluble stannic oxide and left. Another impurity occasionally existing in French sulphuric acid is selenium, supposed to be derived from copper pyrites sometimes substituted for sulphur in the manufacture of the acid. For the mode of detecting and separating this impurity, see the *Journal de Pharmacie* (1872. p. 42). "To neutralize 0·489 Gm. of Sulphuric Acid, diluted with about 10 C.c. of water, should require not less than 9·25 C.c. of potassium hydrate normal volumetric solution (each 0·1 C.c. corresponding to 1 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.*

Tests. "On mixing the Acid carefully with 4 or 5 volumes of alcohol, no precipitate should be formed within one hour (absence of *lead*). If there be carefully poured upon it, in a test-tube, a layer of ferrous sulphate test-solution, the zone of contact should not assume a brown or reddish color (limit of *nitric* or *nitrous acid*). In Sulphuric Acid, diluted with 20 volumes of water, no precipitate should be formed by the addition of silver nitrate test-solution (absence of *hydrochloric acid*), or of hydrogen sulphide test-solution (absence of *lead, arsenic, copper*); nor by supersaturation with ammonia water (*iron*); nor should the acid thus supersaturated leave any fixed residue on evaporation and ignition (absence of *non-volatile impurities*), nor yield any precipitate on addition of ammonium sulphide test-solution (*iron, thallium*, etc.). 1 C.c. of Sulphuric Acid, diluted with 5 C.c. of water, and cooled, should not at once discharge the color of 0·1 C.c. of potassium permanganate decinormal volumetric solution (limit of *sul-*

phurous or *nitrous acid*). If 1 C.c. of a mixture of 1 volume of Sulphuric Acid with 2 volumes of water be mixed with 1 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), no coloration should appear within one hour (limit of *arsenic*)." *U. S.* "Each gramme diluted with 20 or 30 cubic centimetres of *water* should require for neutralization 20·1 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, ammonium, chlorides, nitrates, nitrites, or sulphites. It should yield no appreciable residue on evaporation. *Hydrochloric acid* containing *sodium sulphite*, when poured carefully upon an equal volume of Sulphuric Acid contained in a test-tube, should not cause a red coloration at the junction of the two liquids, and no red precipitate should form on warming the tube (absence of selenium)." *Br.* Denigés proposes to detect arsenic in sulphuric acid by the use of a liquid containing equal volumes of a solution of ammonium molybdate (1 to 10) and sulphuric acid. (*Drug. Circ.*, 1894, 12.)

The following table by Lunge and Isler shows how much hydrated sulphuric acid and how much sulphuric oxide (SO_3) are contained in acid of a given density.

Table of Percentage and Specific Gravity of Sulphuric Acid.

Composition. The normal acid of the sp. gr. 1·842 (1·8485, Ure) consists of one mol. of oxide and one mol. of water. As the hydrogen acts the part of a metal in the compound, the systematic name would be hydrogen sulphate. The oxide consists of one atom of sulphur and three atoms of oxygen. The ordinary commercial acid consists, according to Phillips, of one mol. of oxide and one and a quarter mol. of water. The hydrated acid of Nordhausen has a density as high as 1·89 or 1·9, and consists of two mols. of oxide and one mol. of water ($2SO_3 + H_2O$). This acid is particularly adapted to the purpose of dissolving indigo for dyeing the Saxon blue. When heated gently in a retort, connected with a dry and refrigerated receiver, sulphuric oxide or anhydride distils over, and the common monohydrated acid remains behind. In performing this operation, much difficulty from concussion is avoided, and the product of oxide increased, by introducing a coil of platinum wire into the retort. The oxide may also be obtained by the action of phosphoric oxide on concentrated sulphuric acid, according to the method of Ch. Barreswil. The mixture must be made in a refrigerated retort, and afterwards distilled by a gentle heat into a refrigerated receiver. *Sulphuric oxide* (*solid sulphuric acid*) under 18° C. (64° F.) is in small colorless crystals, resembling asbestos. It is tenacious, difficult to cut, and may be moulded in the fingers like wax, without acting on them. Exposed to the air, it emits a thick opaque vapor of an acid smell. Above 18° C. (64° F.) it is a liquid, very nearly of the density 2.

Medical Properties. For the therapeutic powers and uses of sulphuric acid when administered internally, see *Acidum Sulphuricum Dilutum*. Externally it is sometimes employed as a caustic; but, from its liquid form, it is very inconvenient for that purpose, and should be applied with caution. A plan, however, has been proposed by Professor Simpson by which it becomes very manageable. This consists in mixing it with dried and powdered zinc sulphate sufficient to give it a pasty consistence. *Michel's Paste* consists of strong sulphuric acid three parts, and finely powdered asbestos one part, thoroughly rubbed together. When mixed with

saffron to the consistence of a ductile paste, Velpeau found it a convenient caustic, not liable to spread or be absorbed, and producing an eschar which is promptly detached.

Toxicological Properties. The symptoms of poisoning by this acid are the following. Burning heat in the throat and stomach, extreme fetidness of the breath, nausea and excessive vomitings of black or reddish matter, excruciating pains in the bowels, difficulty of breathing, extreme anguish, a feeling of cold on the skin, great prostration, constant tossing, convulsions, and death. Sometimes there is no pain whatever in the stomach, sensibility being apparently destroyed by the violence of the caustic action. The intellectual faculties remain unimpaired. Frequently the uvula, palate, tonsils, and other parts of the fauces are covered with black or white sloughs. The treatment consists in the administration of large quantities of magnesia, or, if this be not at hand, of solution of soap. The safety of the patient depends upon the greatest promptitude in the application of the antidotes. After the poison has been neutralized, mucilaginous and other bland drinks must be taken freely.

Upon the skin sulphuric acid acts as a very rapid and powerful corrosive. When it has been spilt or thrown upon the person the part should be immediately washed with a weak solution of sodium carbonate or bicarbonate, or soap may be well rubbed into the surface. After the removal and neutralization of the acid, Carron oil or similar protective may be applied. The further treatment is that of a burn.

The holes burnt in linen by sulphuric acid, so long as the texture is undisturbed, are distinguished from those produced by red-hot coals, by the paste-like characters of their edges.

Uses in the Arts. Sulphuric acid is more used in the arts than any other acid. It is employed to obtain many of the other acids; to extract soda from common salt; to make alum and ferric sulphate; to refine petroleum and paraffin; to decompose the neutral fats; to dissolve indigo; to prepare skins for tanning; to prepare phosphorus, chlorinated lime, magnesium sulphate, etc. The arts of bleaching and dyeing cause its principal consumption.

ACIDUM SULPHURICUM AROMATICUM. U. S., Br. Aromatic Sulphuric Acid.

(ĂÇ'Ị-DŬM SŬL-PHU'RỊ-CŬM ĂR-Ọ-MĂT'Ị-CUM.)

Tinctura Aromatica Acida, *P. G.;* Elixir Vitrioli Mynsichti, *G.;* Elixir of Vitriol; Elixir vitriolique, Teinture (alcoolé) aromatique sulphurique, *Fr.;* Saure Aromatische Tinctur, Mynsicht's Elixir, *G.*

"Sulphuric Acid, *one hundred cubic centimeters* [or 3 fluidounces, 3 fluidrachms, 3 minims]; Tincture of Ginger, *fifty cubic centimeters* [or 1 fluidounce, 5½ fluidrachms]; Oil of Cinnamon, *one cubic centimeter* [or 16 minims]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Add the Sulphuric Acid gradually, and with great caution, to *seven hundred cubic centimeters* [or 24 fluidounces] of Alcohol, and allow the mixture to cool. Then add to it the Tincture of Ginger and the Oil of Cinnamon, and afterwards enough Alcohol to make the whole measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Keep the product in glass-stoppered bottles." *U. S.*

"Tincture of Ginger, 10 *fl. ounces* (Imperial measure) or 250 cubic centimetres; Spirit of Cinnamon, ½ *fl. ounce* (Imp. meas.) or 12·5 cubic centimetres; Alcohol (90 per cent.), 29½ *fl. ounces* (Imp. meas.) or 737·5 cubic centimetres; Sulphuric Acid, 3 *fl. ounces* (Imp. meas.) or 2419 *grains*, or 75 cubic centimetres or 138·2 grammes. Mix the Sulphuric Acid gradually with the Alcohol; add the Spirit of Cinnamon and Tincture of Ginger." *Br.*

"It should be preserved in glass-stoppered bottles. Aromatic Sulphuric Acid has the sp. gr. about 0·939, and contains about 20 per cent., by weight, of official Sulphuric Acid, partly in the form of Ethyl-sulphuric Acid. If 4·89 Gm. of Aromatic Sulphuric Acid be mixed, in a small flask, with 15 C.c. of water and boiled for several minutes (so as to decompose the ethyl-sulphuric acid), and the liquid be then allowed to cool, it should require, for complete neutralization, about 18·5 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of absolute or about 1·08 per cent. of official Sulphuric Acid), phenolphtalein being used as indicator." *U. S.*

The specific gravity of the British preparation is "0·922 to 0·926. The neutralizing power of 100 grammes should be equivalent to that of 13·8 grammes of hydrogen sulphate, H_2SO_4."

The formula adopted at the 1880 revision of the U. S. Pharmacopœia was that recommended by Thomas N. Jamieson, *A. J. P.*, 1867, p. 201. The change in the appearance and properties from the preparation of the U. S. P. 1870 was so marked that the wisdom of making so radical a change was doubted. Experience has proved, however, that the new preparation has

not the same tendency to precipitate, and the lightness in color has been offset by more substantial advantages. The British formula has been remodelled to accord with the U. S. P.

Properties. Aromatic sulphuric acid of the older Pharmacopœias was of a deep reddish brown, but it is a straw-colored liquid when freshly prepared according to the direction of the U. S. Pharmacopœia of 1880, of a peculiar aromatic odor, and, when sufficiently diluted, of a grateful acid taste. It has been supposed by some to contain ethylic ether or sulphovinic acid, its main ingredients justifying such a suspicion; but the late Dr. Duncan, of Edinburgh, who originally held this opinion, satisfied himself that the alcohol and sulphuric acid, in the proportions here employed, do not generate a single particle of ethylic ether; and Prof. Attfield has shown that there is no ethyl-sulphuric acid in the official preparation. (*P. J. Tr.*, 1869, p. 471.) It cannot, however, be viewed merely as a sulphuric acid diluted with alcohol and containing the essential oils of ginger and cinnamon, for the difference in odor between fresh and old preparations is quite marked, and a peculiar and agreeable ethereal odor is developed by age. Samples of fresh aromatic sulphuric acid as well as older specimens have been assayed by E. W. Clark, and all were found to be more or less deficient in sulphuric acid; the inference is quite clear that there is some decomposition of sulphuric acid in the preparation upon keeping. (*Pharm. Era*, 1887, p. 69.)

Medical Properties and Uses. This valuable preparation is tonic and astringent. It acts precisely as does the *Acidum Sulphuricum Dilutum*. The dose is from ten to thirty drops (0·6–1·9 C.c.), in a wineglassful of water, repeated two or three times a day. Care must be taken that the teeth are not injured.

ACIDUM SULPHURICUM DILUTUM. U. S., Br. Diluted Sulphuric Acid.

(ĂC'I-DŬM SŬL-PHŪ'RI-CŬM DI-LŪ'TŬM.)

Acide sulphurique dilué, *Fr.*; Verdünnte Schwefelsäure, *G.*

"100 parts by weight should contain 13·65 parts of hydrogen sulphate, H_2SO_4." *Br.*

"Sulphuric Acid, *one hundred grammes* [or 3 ounces av., 230 grains]; Distilled Water, *eight hundred and twenty-five grammes* [or 29 ounces av., 44 grains], To make *nine hundred and twenty-five grammes* [or 32 ounces av., 274 grains]. Pour the Acid gradually, under constant stirring, into the Distilled Water. Keep the product in glass-stoppered bottles. Diluted Sulphuric Acid contains 10 per cent., by weight, of absolute Sulphuric Acid. Specific gravity, about 1·070 at 15° C. (59° F.). It should respond to the reactions and tests given under Sulphuric Acid (see *Acidum Sulphuricum*). To neutralize 4·89 Gm. of Diluted Sulphuric Acid should require 10 C.c. of potassium hydrate normal volumetric solution (each C.c. corresponding to 1 per cent. of the absolute acid), phenolphtalein being used as indicator." *U. S.*

"Sulphuric Acid, 1 *fl. ounce* and 5¼ *fl. drachms* (more exactly, 1·65 *fl. ounces*, Imperial measure) or 1333 *grains*, or 82·7 cubic centimetres or 152·4 grammes; Distilled Water, a sufficient quantity. Half fill with Distilled Water a glass flask the capacity of which to a mark on the neck is *one pint* (Imp. meas.) or one thousand cubic centimetres. Then introduce the Sulphuric Acid, and add very gradually Distilled Water until the mixture, after it has been shaken and cooled to 60° F. (15·5° C.), measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This preparation is sulphuric acid diluted to such an extent as to make it convenient for prescription. It is not exactly coincident in strength as directed in the two Pharmacopœias, the U. S. acid (sp. gr. 1·070) being weaker than the British (sp. gr. 1·094), but slightly stronger than that formerly official; but the difference is not so great as to be of practical importance. The British Pharmacopœia requires that "Each gramme should require for neutralization 2·8 cubic centimetres of the *volumetric solution of sodium hydroxide*." The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposits a grayish-white powder, which is lead sulphate, and from which the diluted acid should be poured off. This noxious salt is thus disposed of; but potassium sulphate, another impurity in the strong acid, still remains. The presence of a little potassium sulphate will do no harm; but, if it should be fraudulently introduced into the strong acid to increase its specific gravity, its amount may be ascertained by saturating the acid, after dilution, with ammonia, and expelling by a red heat the ammonium sulphate formed. Whatever potassium sulphate is present will remain behind. If the directions of the Pharmacopœias are strictly carried out, and the kind of sulphuric

acid is used which is known in commerce as chemically pure, responding to the tests given under the head of *Acidum Sulphuricum*, the official manipulations will be all-sufficient.

Medical Properties and Uses. Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in *typhoid fevers*, and often with advantage. In the convalescence from protracted fevers it acts beneficially as a tonic, exciting the appetite and promoting digestion. As an astringent, it is employed in *colliquative sweats*, *passive hemorrhages*, and diarrhœas dependent on a relaxed state of the mucous membrane of the intestines, *i.e.*, in *serous diarrhœas*. In 1851, Mr. Buxton, of London, called attention to its great value in *choleraic diarrhœas:* his assertions have received abundant confirmation both in this country and in England. (See *Med. Times and Gaz.*, Oct. 1853; *Med. and Surg. Rep.*, ix. 199; *Phila. Med. Times*, iii. 649.) In incipient *cholera* it is an efficient remedy; diluted with water, it may be given every twenty minutes in ordinary cases, every quarter of an hour in severe cases. For *bilious diarrhœa* the acid is not a suitable remedy. In *calculous affections* attended with *phosphatic sediments* it is the proper remedy, being preferable to hydrochloric acid, as less apt, by continued use, to disorder the stomach. The dose is from ten to thirty drops (0·6–1·9 C.c.), three times a day, in a wineglassful of plain or sweetened water. It is added with advantage to infusions of cinchona, the organic alkalies of which it tends to hold in solution. As it is apt to injure the teeth, it is best taken by sucking it through a glass tube or quill. It is much less used in the United States than is the elixir of vitriol. An elegant form of administration is the Compound Infusion of Rose, *U. S.* 1870.

ACIDUM SULPHUROSUM. U. S., Br. Sulphurous Acid.

(ĄÇ'Ị-DŬM SŬL-PHŪ-RŌ'SŬM.)

"A liquid composed of not less than 6·4 per cent., by weight, of Sulphurous Acid Gas [Sulphur Dioxide, $SO_2 = 63·9$], and not more than 93·6 per cent. of water." *U. S.* "An aqueous solution containing 6·4 per cent. of hydrogen sulphite, H_2SO_3, corresponding to 5 per cent. by weight of sulphurous anhydride, SO_2. The sulphurous anhydride may be prepared by burning sulphur in air or oxygen, or by boiling sulphuric acid with carbon, mercury, or copper." *Br.*

Acide sulfureux, *Fr.;* Schweflige Säure, *G.*

"Sulphuric Acid, *eighty cubic centimeters* [or 2 fluidounces, 5 fluidrachms, 38 minims]; Charcoal, in coarse powder, *twenty grammes* [or 308 grains]; Distilled Water, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Introduce the Charcoal into a glass flask having a capacity of about *five hundred cubic centimeters* [or 17 fluidounces], add the Acid, and mix them well. Connect the flask, by means of suitable glass tubing, with a wash-bottle having a capacity of about *two hundred cubic centimeters* [or 6 fluidounces], which is filled to about one-third of its height with water. Through the stopper of the wash-bottle pass a safety-tube, which should reach nearly to the bottom of the bottle, and connect the latter, by means of glass tubing, with a bottle having a capacity of about *fifteen hundred cubic centimeters* [or about 4 pints] and containing *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Distilled Water deprived of air by being boiled shortly before use. The tube should dip about twenty-five millimeters [or 1 inch] below the surface of the Distilled Water. By means of a second tube connect this bottle with another containing a dilute solution of sodium carbonate, to absorb any gas which may not be retained by the Distilled Water. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask containing the Sulphuric Acid and Charcoal, until the evolution of gas has nearly ceased, and, during the passage of the gas, keep the bottle containing the Distilled Water at or below 10° C. (50° F.), by surrounding it with cold water or ice. Finally pour the Sulphurous Acid into dark amber-colored, glass-stoppered bottles, and keep them in a cool place, protected from light." *U. S.*

The British Pharmacopœia no longer gives a detailed process. The process of the U. S. Pharmacopœia is essentially that of Wittstein. The sp. gr. of the U. S. preparation is about 1·022, of the British, 1·025, the latter being slightly stronger.

The rationale of the process is simple. When the sulphuric acid (H_2SO_4) and charcoal are heated together, two molecules of the former give up each an atom of oxygen to the latter, and there are thus produced sulphurous and carbonic acid gases, which, having been first passed through a wash-bottle containing a little water to absorb impurities, are received into the distilled water, where the sulphurous acid is absorbed, whilst the greater part of the carbonic acid escapes, $4H_2SO_4 + C_2 = 2CO_2 + 4H_2O + 4SO_2$. The excess of sulphurous acid gas which escapes absorption is in the U. S. process received into a solution of sodium

carbonate, and condensed. In the Br. process the point of saturation is roughly indicated by the bubbles formed by the escape of the gas from the distilled water being equal in size to those formed in the wash-bottle. If there be any difficulty in getting the solution up to the official strength, the proportionate amount of sulphuric acid and of charcoal should be increased, and care exercised that the gas pass through the water in an abundant stream. The direction to keep the acid in well-stoppered bottles, in a cool place, is necessary in consequence of the strong tendency of the gas to escape and to undergo oxidation. An incidental advantage of the U. S. process is the production of sodium sulphite. Old sulphurous acid often contains sulphuric acid, which may be nearly all removed by the cautious addition of barium sulphite and the removal by filtration of the precipitated sulphate.

According to Mr. W. L. Scott (*P. J. Tr.*, Oct. 1869, p. 217), the best results are obtained when sulphuric acid containing 75 per cent. of anhydrous acid is employed; when a too concentrated acid is used, a part of it is entirely reduced and sulphur deposited, while a too dilute acid causes the evolution of hydrogen sulphide. He also affirms that a purer gas is obtained by placing a little lead sulphite and a few pieces of charcoal in the wash-bottles.

Prof. F. C. Calvert gives a process for preparing this acid on a large scale by which he avoids all the inconveniences usually attendant on its manufacture, and has prepared thousands of gallons daily of a saturated solution. It consists in burning sulphur in a small furnace, and conducting the acid gas through earthenware tubes surrounded with water so as to cool them. The gas is then made to ascend through a wooden tube 40 feet high and about 4 feet wide, sometimes called a coke scrubber, filled with pumice stone previously washed first with hydrochloric acid and then with water. A certain amount of water is introduced into the tube from above, which, in its descent, meets and dissolves the gas, and runs out saturated from the bottom of the tube into an air-tight reservoir. (*P. J. Tr.*, xvii. 512.) Where sulphurous acid is to be used as a disinfectant, carbon disulphide, either pure or mixed with petroleum, may be burned in the room to be disinfected. Keates (*Chem. News*, Dec. 8, 1876) suggests the use of a suitable lamp. Stevenson uses an open copper dish or porcelain capsule, and simply ignites the liquid: care should be used, however, as the disulphide is very inflammable and volatile. A purer sulphurous acid than the official may be made by John Kennedy's process, that of reducing sulphuric acid with metallic copper and passing the gas through a cylinder containing lumps of moist charcoal and then through a wash-bottle. The by-product is available as copper sulphate. (*A. J. P.*, 1886, p. 226.)

Properties. The official sulphurous acid is a strong solution of sulphurous oxide gas. The oxide is an irrespirable gas, of a suffocating odor familiar to every one as that of burning sulphur, which is converted into it by combustion. If inhaled in the concentrated state, it proves fatal. Cold reduces it to a colorless liquid, which boils at —10·5° C. (13·1° F.). It has the sp. gr. 2·21, liquefies at —10° C. (14° F.), has a strong acid reaction, extinguishes burning bodies, has the power of bleaching many colored substances, and has a strong affinity for oxygen, with which it combines in the presence of water, forming sulphuric acid. Water at 18° C. (65° F.) takes up about 50 volumes of gas, and the solution has the sp. gr. 1·04. (*Brande and Taylor.*) Liquefied sulphurous acid gas (oxide) is now manufactured by Pictet in Geneva, and is sent into commerce in copper cylinders. It also forms the basis of the Pictet ice-making process. The Pictet machines are constructed to use either the pure SO_2 or the "Pictet fluid," a mixture of compressed carbon dioxide and sulphur dioxide.*

Sulphurous acid sometimes exists as an impurity in hydrochloric, acetic, and other acids; according to P. Schweitzer, the minutest quantity may be detected by dissolving zinc in the suspected acid, when, if sulphurous acid be present, the odor of hydrogen sulphide will be at once perceived. (*Chem. News*, xxiii. 293.)

Official sulphurous acid is a colorless liquid, having a smell of burning sulphur, and a sulphurous somewhat astringent taste. When exposed to the air it slowly absorbs oxygen, with the formation of sulphuric acid, and acquires a sour taste, and the property of changing vege-

* *Thiocamph.* Under this name Dr. J. E. Reynolds has introduced a disinfectant, which is prepared by acting on camphor with sulphur dioxide. At ordinary temperatures SO_2 requires a pressure of more than two atmospheres to liquefy it; but camphor, owing to chemical attraction, can liquefy it without any pressure whatever. In the liquid thus prepared several known bactericides are dissolved. Thiocamph can be preserved without pressure in bottles at mean temperature; mere exposure of the liquid in a thin layer to the air determines the steady evolution of sulphur dioxide. The contents of a six-ounce bottle will yield over 20,000 C.c. of SO_2. One ounce of thiocamph shaken up with a quart of water forms a powerful disinfectant for ordinary purposes, while a more dilute solution (1 oz. to the gallon) can be used for soaking clothes which have been in contact with infected persons. (*Chem. News*, June 22, 1890, p. 291.)

table blues to red. When kept in closed vessels exposed to the sunlight, a portion of it is decomposed, sulphur being deposited and sulphuric acid formed by the union of the liberated oxygen with other portions of the acid. (*A. J. P.*, xlii. 352.) It should be entirely volatilized by heat. It decolorizes iodine by producing hydriodic acid, and on this fact is based the Br. test before given. It decomposes bone calcium phosphate.

"A colorless liquid, of the characteristic odor of burning sulphur, and of a very acid, sulphurous taste. Specific gravity, not less than 1·035 at 15° C. (59° F.). By heat it is completely volatilized. Litmus paper moistened with the Acid is first reddened and afterwards bleached. On gently heating a few C.c. of the Acid in a test-tube, the gas evolved will blacken a strip of paper moistened with mercurous nitrate test-solution, but will not affect one moistened with lead acetate test-solution. On mixing, in a test-tube, 1 C.c. of Sulphurous Acid with 5 C.c. of diluted hydrochloric acid, and adding a small piece of pure zinc, hydrogen sulphide gas will be evolved, which will blacken a strip of paper moistened with lead acetate test-solution. If to 10 C.c. of Sulphurous Acid there be added 1 C.c. of diluted hydrochloric acid, and afterwards 1 C.c. of barium chloride test-solution, not more than a very slight turbidity should be produced (limit of *sulphuric acid*). If 0·7 Gm. of Sulphurous Acid be diluted with 25 C.c. of distilled water and a little starch test-solution be added, at least 14 C.c. of iodine decinormal volumetric solution should be required, before a permanent blue tint is developed (each C.c. corresponding to 0·16 per cent. of Sulphur Dioxide)." *U. S.* "It gives but a slight precipitate with *solution of barium chloride* (absence of excess of sulphates), but a copious precipitate if *solution of chlorine* also be added. When evaporated it leaves no residue. Specific gravity 1·025. Mixed with 100 times its volume of recently boiled and cooled *water*, and a little *mucilage of starch*, it should not acquire a permanent blue color with the *volumetric solution of iodine* until, for each gramme of the acid, 15·7 cubic centimetres of the *volumetric solution of iodine* have been added." *Br.*

Medical Properties and Uses. Sulphurous acid is a powerful antiseptic and germicide, arresting putrefaction and other fermentations by killing the organisms which produce them. It is supposed to be thus destructive by its anti-oxygenizing or reducing influence, suffocating organic beings by denying them the oxygen necessary to their existence; but it probably acts also by a physiological property independently of its mere chemical effect. According to the experiments of Dr. L. Pfeiffer (*Arch. f. Exper. Path.*, xxvii.), the sulphites are capable of causing death by paralyzing the heart and also the respiratory and other motor nerve-centres, but are so rapidly and completely changed into the sulphates that unless given in enormous amount they exert very little influence upon the system: 96·5 per cent. of the sulphite was regained from the urine as a sulphate, and 86 per cent. passed out in five hours after ingestion. Although Dr. Robert Bird affirms that sulphurous acid and its salts are powerful antipyretics (*Amer. Journ. Med. Sci.*, lviii. 236), and the acid in the form of the fumes of burning sulphur has been used by inhalation in *low fevers*, *diphtheria*, and *whooping-cough* with alleged advantage, yet the sulphites are at present employed in medicine almost solely as germicides and parasiticides. In *pyrosis* and in cases of *sarcinæ ventriculi* sulphurous acid may be taken internally; but one of the sulphites, as sodium sulphite, is perhaps preferable for the purpose, as it yields the acid always by decomposition in the stomach. As an external application, it is used in *psora*, the different forms of *porrigo*, *trichosis of the scalp*, *pityriasis versicolor*, and the *thrush* of children, all *parasitic affections*, either animalcular or cryptogamous, generally yielding to it, if proper care be taken, by previous removal of scabs or scales, to bring it into contact with the morbific cause. The dose for internal use is a fluidrachm (3·75 C.c.), largely diluted with water. When locally used it should be diluted with two or three measures of water or of glycerin, and applied as a lotion, or by cloths wet with it. Sulphurous acid constitutes the active principle of the fumes of burning sulphur, so much used for disinfecting purposes.

ACIDUM TANNICUM. U.S., Br. Tannic Acid. [Gallotannic Acid, Digallic Acid.]

$HC_{14}H_9O_9$; 321·22. (ĂṢ'Ị-DŬM TĂN'NỊ-CŬM.) $C_{14}H_{10}O_9$ (chiefly); 322.

"An organic acid obtained from nut-gall." *U. S.* "Tannic acid, $C_{14}H_{10}O_9.2H_2O$, may be extracted by water-saturated ether from Galls which have been subjected to a special fermentation." *Br.*

Tannin, Acidum Gallo-tannicum, Tanninum; Acide tannique, Tannin, *Fr.*; Gerbsäure, Tannin, *G.*

The present British Pharmacopœia does not give a detailed process for preparing tannic acid, the former British Pharmacopœia adopted a process which was almost identical with that of the U. S. P. (1870), both being essentially the process of Leconnet, modified by Dominé,

which had been substituted for that of Pelouze previously employed in both Pharmacopœias. The process of the British Pharmacopœia (1885) is as follows. "Galls in powder, Ether, of each a sufficient quantity. Expose the powdered galls to a damp atmosphere for two or three days, and afterwards add sufficient ether to form a soft paste. Let this stand in a well-closed vessel for twenty-four hours, then, having quickly enveloped it in a linen cloth, submit it to strong pressure in a suitable press, so as to separate the liquid portion. Reduce the pressed cake to powder, mix it with sufficient ether, to which one-sixteenth of its bulk of water has been added, to form again a soft paste, and press this as before. Mix the expressed liquids, and expose the mixture to spontaneous evaporation until, by the aid subsequently of a little heat, it has acquired the consistence of a soft extract; then place it on earthen plates or dishes, and dry it in a hot-air chamber at a temperature not exceeding 212° F. (100° C.)."*

While the Pelouze process yields the tannic acid probably in a somewhat purer state than Leconnet's, it is less easy of performance, and much less productive; and the product of the existing formula is sufficiently pure for all practical purposes. The addition of a little alcohol—8 per cent., for example—to the ethereal menstruum still further increases the product. The exposure of the powdered galls to a damp atmosphere for two or three days is for the purpose of inducing a special fermentation, whereby the yield of tannin is materially increased. There appear to be two coloring principles in galls, one soluble in ether and not in alcohol, the other in alcohol and not in ether. Hence, while the tannic acid, in whichever way procured, is yellowish, that obtained by ether has a greenish tint, while that obtained by the addition of alcohol is slightly brownish. In consequence of the mode in which the acid is dried, in thin layers, on tinned or glass plates, and equally exposed to the heat above and below, it froths up on the escape of the ether, and concretes in a soft, cellular, friable form, which is strikingly characteristic of the preparation made in strict accordance with the formula.

From a superficial examination of this process, it might appear that the result can be nothing more than an ethereal extract; but it is necessary that the ether employed should contain water, as it is directed to be washed; and yet the quantity of water is so small that it can hardly operate by its mere solvent power. The circumstances attendant upon the process of Pelouze afford the means of a satisfactory explanation, which was first suggested by M. Beral. In this, the powdered galls are submitted to percolation by watered ether, and the liquid which passes separates into two layers, a heavier which sinks to the bottom and a lighter which floats upon the surface. It is the heavier which contains the tannic acid, and from which the acid is obtained by evaporation. The most probable explanation is that ether, water, and tannic acid unite to form a definite compound, in which the affinities are too feeble to resist the tendency of the ether to rise in vapor, and which is, therefore, decomposed by its evaporation. The proportion of the menstruum to the galls is very small, much smaller than would be employed to obtain an extract; and the whole or nearly the whole of both liquids is probably occupied in the formation of the definite compound referred to, thus leaving little or none to act merely as solvents. Hence the exclusion from the resulting acid, in great measure, of the other soluble constituents of the galls; and the slight amount of impurity really present in the acid is probably owing to the action of that small quantity of the menstruum not occupied in forming the liquid compound. Opinion is not altogether united in this explanation, but it is that which appears to us the best to account for the phenomena of the case. It has been stated that the tannic acid obtained by either process has a more or less yellowish tint. From this, according to F. Kummel, it may be freed by the percolation, through recently ignited animal charcoal, of its solution in a mixture of ether and alcohol. It has, too, a slight odor, which, according to Prof. Procter, is derived from a volatile odorous principle existing in galls, which he succeeded in separating from the acid by the action of benzol. From 30 to 35 per cent. of tannic acid is obtained from galls by Pelouze's method; 60 per cent. by that of Leconnet.

Prof. Henry Trimble and J. C. Peacock recommend acetone as a valuable solvent for extracting tannin from oak bark (*Proc. A. P. A.*, 1893, p. 110). B. L. DeGraffe (*A. J. P.*, 1896, 313) recorded investigations upon the plants of the Ericaceæ to determine the character of their tannins; acetone and acetic ether were used as solvents. For Sisley's method of preparing *pure* tannin, see *Proc. A. P. A.*, 1894, 1087.

* For the preparation of tannin from Chinese galls, Oscar Rothe proposes the following as a superior process. Macerate eight parts of the powdered galls with twelve of ether and three of strong alcohol for two days, decant, renew the menstruum, and finally express. Mix the liquids, and after standing decant from the sediment, add twelve parts of water, recover the alcohol and ether by distillation, rapidly filter the aqueous solution, and quickly evaporate by means of a steam bath; dry, and pulverize the residue. (*A. J. P.*, xlii. 403.)

The term *tannin* is applied to a class of vegetable principles the aqueous solutions of which give blue or green colors or precipitates with ferric salts, and precipitate solutions of gelatin and albumen. They are mainly glucosides. Chemists have recognized two kinds, one distinguished by producing a bluish-black precipitate with ferric salts, and the other characterized by producing a greenish-black or dark olive precipitate with the same salts. The former is the one which has received most attention, and from an examination of which the characters of tannin have generally been given. It is the substance described in this article. It is called, for the sake of distinction, *gallotannic acid*. According to Pettenkofer, it is found only in perennial plants, indicating some relation to the production of woody fibre. (*Buchner's Neues Repert.*, iii. 74–76.) Prof. Henry Trimble (*The Tannins*, vol. ii. p. 132, Phila., 1894) classifies the tannins into two main groups: Group *a*. Gallotannic acid, chestnut wood tannin, chestnut bark tannin, pomegranate bark tannin, and sumac tannin. Group *b*. Oak bark tannin, mangrove tannin, canaigre tannin, rhatany tannin, kino tannin, catechu tannin, and tormentil tannin. R. Wagner (*Bull. Soc. Chim.*, 1866, ii. 461) divides tannin into two great classes: pathological, found only in diseased vegetable tissue, as gallotannic acid, etc.; and physiological, occurring in leaves, bark, wood, etc., in a natural state, as quercitannic acid, etc.

For another scheme of classification of the tannins, based on the products they yield when heated alone, when heated with dilute acid, and when fused with caustic alkali, see Allen, *Com. Org. Anal.*, 2d ed., vol. iii., part i., p. 77.

Properties. Pure tannic acid is solid, uncrystallizable, white, or slightly yellowish, inodorous,* without bitterness, very soluble in water, much less soluble in alcohol and ether, especially when anhydrous, insoluble in the fixed and volatile oils.

The Pharmacopœia thus describes Tannic Acid: "A light yellowish, amorphous powder, usually cohering in form of glistening scales or spongy masses, odorless, or having a faint, characteristic odor, and a strongly astringent taste; gradually turning darker when exposed to air and light. Soluble, at 15° C. (59° F.), in about 1 part of water, and in 0·6 part of alcohol; very soluble in boiling water, and in boiling alcohol; also in about 1 part of glycerin, with the intervention of a moderate heat; freely soluble in diluted alcohol, sparingly in absolute alcohol; almost insoluble in absolute ether, chloroform, benzol, or benzin. When heated on platinum foil, the Acid is gradually consumed without leaving more than 0·2 per cent. of ash. Tannic Acid has an acid reaction upon litmus paper. The addition of a small quantity of ferric chloride test-solution to an aqueous solution of the Acid produces a bluish-black color or precipitate. On adding to an aqueous solution (1 in 100) of Tannic Acid a small quantity of calcium hydrate test-solution, a pale bluish-white, flocculent precipitate is produced which is not dissolved on shaking (difference from *gallic acid*), and which becomes more copious and of a deeper blue by the addition of a moderate excess of calcium hydrate test-solution, while a large excess of the latter imparts a pale pinkish tint to the solution. The aqueous solution of the Acid produces precipitates with most alkaloids and bitter principles, and with test-solutions of gelatin, albumen, and starch (distinction from *gallic acid*). On dissolving 2 Gm. of Tannic Acid in 10 C.c. of boiling water, and allowing the liquid to cool, no turbidity should be produced on diluting 5 C.c. of the solution with 10 C.c. of alcohol (absence of *gum* or *dextrin*), or with 10 C.c. of water (absence of *resin*)." *U. S.* "It is precipitated from its aqueous solution and loses its astringency in the presence of many mineral salts and acids. The aqueous solution precipitates *solutions of isinglass*, *albumen*, alkaloids, and *tartarated antimony*, and gives with *test-solution of ferric chloride* a bluish-black color. It should leave no appreciable residue when incinerated with free access of air." *Br.*

Exposed to heat, tannic acid partly melts, swells up, blackens, takes fire, and burns with a brilliant flame. Thrown on red-hot iron, it is entirely dissipated. Its solution reddens litmus, and it combines with most of the salifiable bases. It forms with potassa a compound but slightly soluble, and is, therefore, precipitated by this alkali or its carbonates from a solution which is not too dilute, though a certain excess of alkali will cause the precipitate to be redissolved. Its combination with soda is much more soluble; and this alkali affords no precipitate, unless with a very concentrated solution of tannic acid. With ammonia its relations are simi-

* Commercial tannic acid often has a decided odor, which Prof. Procter, after a practical investigation, believed to be owing chiefly to the presence of the odorous principle of the galls, though sometimes to matter derived from the ether with which it is prepared. (*A. J. P.*, 1865, p. 53.) According to M. Heinz, the odor is due to a greenish resinous principle, which may be separated by dissolving the acid in twice its weight of hot water, adding one-fourth part of ether, agitating slowly, allowing the coagulated coloring matter to precipitate, filtering, and evaporating. (*Journ. de Pharm.*, xv. 308.) Commercial tannic acid is often impure; in 9 samples tested by T. Maben (*P. J. Tr.*, xv. 851) the percentage of pure tannic acid varied from 54 to 86 per cent.

lar to those with potassa. Lime and magnesia, added in the state of hydrates, form with it compounds of little solubility. The same is the case with most of the metallic oxides, when presented in the state of salts to a solution of potassium tannate. Tannic acid even when in the uncombined state precipitates many of the metallic salts, especially those of lead, copper, silver, uranium, chromium, mercury, antimony teroxide, and stannous oxide. With ferric salts it forms a black precipitate, which is a compound of tannic acid and the iron, and is the basis of ink. It does not disturb the solutions of the pure salts of ferrous oxide. Several of the alkaline salts precipitate it from its aqueous solution, either by the formation of insoluble compounds or by simply abstracting the solvent. Potassium chlorate when rubbed up with it explodes with great violence, and several serious accidents have occurred during the attempt to dispense such a mixture.

Tannic acid unites with all the vegetable alkaloids, forming compounds which are for the most part of a whitish color, and but very slightly soluble in water; though they are soluble in the vegetable acids, especially acetic, and in alcohol. In this latter respect they differ from most of the compounds which tannic acid forms with other vegetable principles. On account of this property of tannic acid, it has been employed as a test of the vegetable alkaloids; and it is so delicate that it will throw down a precipitate from their solution, even when too feeble to be disturbed by ammonia.

It has an affinity for several acids, and when in solution affords precipitates with sulphuric, nitric, hydrochloric, phosphoric, and arsenic acids, but not with oxalic, tartaric, lactic, acetic, or citric. The precipitates are considered as compounds of tannic acid with the respective acids, and are soluble in pure water, but insoluble in water with an excess of acid. Hence, in order to insure precipitation, it is necessary to add the acid in excess to the solution of tannic acid. Strecker, however, denies that the precipitates are compounds of the tannin with the acid, and maintains that they are tannin imbued with free acid. (*Chem. Gaz.*, No. 287, p. 370.)

When tannic acid, iodine, and water are mixed, a reaction takes place, by which the water is decomposed; its hydrogen forming with the iodine hydriodic acid, which combines with a portion of the tannic acid and remains in solution; while the oxygen of the water combines with another portion of the tannic acid, to form a compound, which, being insoluble, is precipitated. The iodized solution thus obtained is capable of dissolving more iodine, and holding it in permanent solution, however much diluted. (Socquet and Guilliermond, *Journ. de Pharm.*, xxvi. 280.) Iodine in a liquid containing tannic acid cannot be detected by starch; but if the liquid is placed in a watch-glass, ferrous sulphate added, and the glass covered with a starched paper, ferric tannate being precipitated, the blue color soon appears. (*A. J. P.*, xlvii. 398.)

Griessmayer (*Zeitschr. f. Chemie*, 1873) proposes a test for tannin and free alkalies. On mixing a drop of a solution of tannin with 1 C.c. of $\frac{1}{100}$ normal solution of iodine, the reddish color of the iodine solution instantly disappears; if one drop of solution of ammonia be now added (previously diluted with ten times its bulk of water), a brilliant red color is produced which is quite permanent. Tannic acid precipitates solutions of starch, albumen, and gluten, and forms with gelatin an insoluble compound, which is the basis of leather. J. Napier Spence (*Journ. Soc. Chem. Ind.*, 1891, p. 1114) has reviewed all the current tests for distinguishing between tannic acid and gallic acid; for an abstract see *Proc. A. P. A.*, 1892, p. 1032.

Liebig first gave it the formula $C_{18}H_8O_{13}$. Mulder, however, considered it isomeric with gallic acid, and gave for its formula $C_{14}H_{10}O_9$; and both Julius Löwe and Hugo Schiff confirmed the correctness of this formula. (*A. J. P.*, xxv. 223; xlvii. 208.) Strecker looked upon it as a compound of gallic acid and glucose, the latter of which is destroyed in the spontaneous change that moistened galls undergo by time. (See *Acidum Gallicum.*) Hugo Schiff, however, asserts that it is not a glucoside; that glucose exists in commercial tannic acid as an impurity, and is not a necessary part of it, and that it is a "first anhydride," formed from two molecules of gallic acid by the abstraction of water, according to the reaction $2C_7H_6O_5 - H_2O = C_{14}H_{10}O_9$, and is consequently digallic acid, and this view at present prevails. (See *Acidum Gallicum.*) (*Chem. News*, xxix. 73; also *A. J. P.*, xlvi. 234.)*

* Various plans have been proposed of estimating the quantity of tannic acid, which is an object of importance to tanners, as enabling them to judge of the value of their tanning materials; but on this point we must content ourselves, from want of space, with referring to *A. J. P.* (1859, p. 427; 1861, p. 164; 1863, p. 519; 1864, p. 314); also a paper by Mr. John Watts in the *P. J. Tr.* (1867, p. 515); also one by H. R. Procter, in the *Chem. News* (1874, p. 51), and one by MM. A. Muntz and Ramspacher (*Journ. de Pharm.*, xx. 287); also *Journ. de Pharm.*, 1874, pp. 445–447; *A. J. P.*, March, 1874, and Aug. 1877; *N. R.*, Aug. 1878; *N. R.*, 1882, pp. 150, 185; *P. J. Tr.*, 1885, pp. 121, 850. See also paper by S. J. Hinsdale in *Western Druggist*, 1891, p. 445, and a monograph on "The Tannins," by Prof. Henry Trimble (J. B. Lippincott Company, 1892). John H. Yocum, after reviewing various methods of estimating tannin, concludes that the "hide-powder" method is the most practical and useful. (*Amer. Chem. Soc.*, Jan. 9, 1897.)

Commercial tannin from galls is an indefinite mixture of digallic acid (see *Acidum Gallicum*) and the glucoside. That this view is correct is evident from the fact that it yields from 0 to 22 per cent. of glucose when acted upon by dilute acids. The glucoside $C_{34}H_{28}O_{22}$ would yield 23 per cent. (Allen, *Com. Org. Anal.*, 2d ed., i. 283.)

Medical Properties and Uses. Tannic acid is the chief principle of vegetable astringents, and has an advantage over the astringent extracts in the comparative smallness of its dose, which renders it less apt to offend an irritable stomach. In most of the vegetable astringents it is associated with more or less bitter extractive, or other principle which modifies its operation and renders the medicine less applicable than it otherwise would be to certain cases in which there is an indication for pure astringency without any tonic power. Such is particularly the case in the active *hemorrhages;* and tannic acid, in its separate state, is here preferable to the native combinations in which it ordinarily exists. In *diarrhœa* it is probably more beneficial than ordinary astringents, as less liable to irritate the stomach and bowels. Owing to its very powerful coagulant action upon albumen, it is, however, absorbed only after conversion into gallic acid, and consequently has been superseded by the latter agent in all cases in which it must reach the diseased surface through the blood, or in which a general astringent action is desired. Locally applied, it is much more powerful than gallic acid, and is very largely employed (see *Collodium Stypticum*), as in *hemorrhages* from external surfaces or from mucous membranes which can be reached from without, *relaxation of the uvula*, *coryza*, *chronic inflammation of the fauces*, *diphtheria*, *toothache*, *aphthæ*, *excessive salivation*, *leucorrhœa*, *chapped nipples*, *gleet*, *gonorrhœa*, *flabby* and *phagedænic ulcers*, *piles*, *chilblains*, etc. It may be applied in solution of varying concentration according to the necessities of the case. When a very powerful influence is desired, the solution in glycerin may be used. (See *Glyceritum Acidi Tannici.*) In *affections of the rectum* it may be used in the form of a suppository. In *diseases of the uterus* it has been recommended in the form of a cylindrical pencil about an inch long and two lines thick, made with 4 parts of the acid to 1 part of tragacanth, with a little crumb of bread to give the mixture due flexibility. Dose, from three to ten grains (0·20–0·67 Gm.).

As already stated, tannic acid is probably converted into gallic acid before absorption: it is eliminated through the kidneys in the form of gallic and pyrogallic acids. (*Chem. Gaz.*, No. 136, p. 231.) In the largest amounts it produces only a mild gastro-intestinal irritation.

ACIDUM TARTARICUM. U. S., Br. Tartaric Acid.

$H_2C_4H_4O_6$; 149·64. (ĂQ'I-DŬM TĂR-TĂR'I-CŬM.) $H_2C_4H_4O_6$; 150.

"An organic acid usually prepared from argols." *U. S.* "Tartaric Acid, or dextro-rotatory hydrogen tartrate, $C_4H_6O_6$, prepared from acid potassium tartrate. In constitution it may be regarded as dioxysuccinic acid, or dihydroxysuccinic acid,

CH.OH.COOH
|
CH.OH.COOH." *Br.*

Sal Essentiale Tartari; Acide du Tartre, Acide tartrique, *Fr.;* Weinsteinsäure, Weinsäure, *G.;* Acido tartarico, *It., Sp.*

No formula for the preparation of tartaric acid is given in either Pharmacopœia. It is extracted from *tartar*, or argol, a peculiar substance which is deposited on the inside of wine-casks during the fermentation. Tartar, when purified and reduced to powder, is the cream of tartar of the shops, and consists of acid potassium tartrate. (See *Potassii Bitartras.*) The following is the former British process:

"Take of Acid Tartrate of Potassium *forty-five ounces* [av.]; Distilled Water *a sufficiency;* Prepared Chalk *twelve ounces and a half* [av.]; Chloride of Calcium *thirteen ounces and a half* [av.]; Sulphuric Acid *thirteen fluidounces.* Boil the Acid Tartrate of Potassium with two gallons [Imp. measure] of the Water, and add gradually the Chalk, constantly stirring. When the effervescence has ceased, add the Chloride of Calcium dissolved in two pints [Imp. meas.] of the Water. When the tartrate of calcium has subsided, pour off the liquid, and wash the tartrate with Distilled Water until it is rendered tasteless. Pour the Sulphuric Acid, first diluted with three pints [Imp. meas.] of the Water, on the tartrate of calcium, mix thoroughly, boil for half an hour with repeated stirring, and filter through calico. Evaporate the filtrate at a low temperature until it acquires the sp. gr. of 1·21, allow it to cool, and then separate and reject the crystals of sulphate of calcium which have formed. Again evaporate the clear

liquor till a film forms on its surface, and allow it to cool and crystallize. Lastly, purify the crystals by solution, filtration (if necessary), and recrystallization." *Br.* (1885).

Tartaric acid was first obtained in a separate state by Scheele in 1770. The process consists in saturating the excess of acid in potassium bitartrate or cream of tartar with calcium carbonate, and decomposing the resulting insoluble calcium tartrate by sulphuric acid, which precipitates in combination with the lime, and liberates the tartaric acid. The equivalent quantities are two mols. of the acid tartrate and one mol. of calcium carbonate. The process, when thus conducted, furnishes one half only of the tartaric acid. The other half may be procured, as in the British process, by decomposing the neutral potassium tartrate, remaining in the solution after the precipitation of the calcium tartrate, by calcium chloride in excess. By double decomposition, potassium chloride will be formed in solution, and a second portion of calcium tartrate will precipitate, which may be decomposed by sulphuric acid together with the first portion. The process, when thus conducted, will, of course, furnish twice as much tartaric acid as when the acid salt only is decomposed.

The reactions are as follows: $2\,KHC_4H_4O_6 + CaCO_3 = K_2C_4H_4O_6 + CaC_4H_4O_6 + H_2O + CO_2$, then $CaC_4H_4O_6 + H_2SO_4 = CaSO_4 + H_2C_4H_4O_6$, and $K_2C_4H_4O_6 + CaCl_2 = (KCl)_2 + CaC_4H_4O_6$, then $CaC_4H_4O_6 + H_2SO_4 = CaSO_4 + H_2C_4H_4O_6$.

Formerly all the tartaric acid used in America was imported from England and France, the amount in some years being as much as 500,000 lbs. annually; but it is now made in the United States not only of better quality, but actually cheaper than the imported acid costs in bond. The importations of argol, or crude tartar, are, however, considerable. In 1895 they amounted to 27,911,122 lbs., valued at $1,893,730; in 1896, 28,481,665 lbs., valued at $2,724,700; in 1897, 23,457,576 lbs., valued at $1,967,042.

Preparation on the Large Scale. To obtain the tartaric acid from the crude materials (argol and wine lees), the only method suitable for technical purposes is the precipitation of the acid potassium tartrate as calcium tartrate and subsequent preparation of the tartaric acid from the latter. The methods of obtaining the calcium tartrate vary according to the nature of the crude material. A suitable method of producing it from argol is to mix the argol, preferably in the form of a powder, with water, and boil, after the addition of some hydrochloric acid; the best proportions are 4 to 5 cubic millimetres of water with 110 to 120 kilos of crude hydrochloric acid (20° to 22° B.) to about 500 kilos of argol. Milk of lime is then added to the boiling mass until this is nearly neutral, when calcium tartrate is precipitated and neutral potassium tartrate and calcium chloride left in solution. The neutral potassium tartrate is decomposed either by boiling with a sufficient amount of calcium sulphate or by adding calcium chloride solution, an excess of the precipitant being avoided in either case. The small amount of acid potassium tartrate purposely left in the liquid, when treating the latter with milk of lime, is decomposed with pure precipitated calcium carbonate. The object of not adding the milk of lime to the neutral point or in excess is to avoid the precipitation of iron oxide or alumina. The solution must still remain perceptibly acid after the addition of the calcium carbonate. When cooled to about 40° C., the liquid is filtered with the aid of a suction-pump, and the residue washed with water. The dark brown filtrate was formerly treated to recover the calcium chloride and potassium sulphate, but, owing to the expense of the recovery and purification, it is now a waste product.

In the oldest methods of obtaining calcium tartrate from wine lees the latter were boiled with water and hydrochloric acid, the clear solution removed, and the residue treated with more water. As the extraction was very incomplete, these methods have not been employed for the last thirty years. When filtration of the lees was first attempted it was found that the pores of the filter became clogged, and that even under a pressure of four or five atmospheres no liquid would pass through. This difficulty was overcome by the process of Dietrich and Schnitzer, in which the albuminoid substances are coagulated by heating for about six hours under a pressure of four or five atmospheres. This method has been in general use for about thirty years. Wet lees, when thus treated, can be readily filtered. Dried lees are crushed, stirred in a tank with water, and heated by steam for some time, until air is completely expelled, before being heated in the pressure-boiler. According to the author's experience, preliminary boiling for more than half an hour is superfluous.

During the process of heating the lees the steam passing from the apparatus carries with it volatile empyreumatic products derived from the decomposed albuminoids. These have a very offensive odor, and should be conveyed into a factory chimney of sufficient height, so that the evil-smelling vapors are drawn up and decomposed by the furnace gases.

When the heating is finished, the steam outlet-pipe is opened and the pressure allowed to fall to from one to one-half atmosphere, this pressure being required to force the lees from the boiler into a tank, which may be suitably constructed of wood. Here they are mixed with water, which has previously been put into the tank, and the requisite quantity of crude hydrochloric acid (21° to 22° B.). Experience has shown that for every 100 parts by weight of argol in the lees 100 parts of acid are required. Too little acid causes decomposition of argol in the cloths of the filter-press, while too much destroys the cloths, and more lime is needed to neutralize the filtrate. If the conditions are right, the filtered liquid should have a specific gravity of about 6° B.

The acidified lees are pressed and washed, the washings being used instead of clear water for mixing with the next charge of lees from the pressure-boiler. The tartaric acid in the filtrate is precipitated with lime and calcium carbonate, and the remainder of the process is the same as in the case of the argols, with the exception that there is no necessity to add calcium chloride or calcium sulphate.

The calcium tartrate obtained from wine lees is of a clear gray color, and considerably purer than the dark gray or dark brown product from argol. (*Journ. Soc. Chem. Ind.*)

Oscar Ficinus, of Bensheim, proposes the following process to procure a pure tartaric acid. Saturate the crude tartar with calcium carbonate, and decompose the resulting calcium tartrate with solution of zinc chloride, whereby calcium chloride and zinc tartrate are produced. The latter is almost insoluble, and is completely decomposed by hydrogen sulphide. The residuary zinc sulphide may again be converted by means of hydrochloric acid into zinc chloride and hydrogen sulphide, so that the expense of the process is very small. The liquid filtered from the precipitated zinc sulphide, containing tartaric and sulphydric acids in solution, is heated for some time to 60°–80° C. (140°–176° F.), in order to dissipate the latter acid, filtered from the precipitated sulphur, and concentrated to the point of crystallization. (*Arch. d. Pharm.*, April, 1879, p. 310.) It is asserted that in Hungary and Southern Italy tartaric acid of extreme purity is prepared; that occurring in flat, crystalline crusts being chemically pure, that in pointed crystals containing a little sulphuric acid.

Properties. "Colorless, translucent, monoclinic prisms, or crystalline crusts, or a white powder, odorless, having a purely acid taste, and permanent in the air. Soluble at 15° C. (59° F.), in about 0·8 part of water, and in 2·5 parts of alcohol; in about 0·5 part of boiling water, and in about 0·2 part of boiling alcohol; also in 250 parts of ether; nearly insoluble in chloroform, benzol, or benzin. When heated for some time at 100° C. (212° F.), the powdered crystals do not suffer a sensible loss of weight. At 135° C. (275° F.) the Acid melts.* At higher temperatures it is gradually decomposed, emitting the odor of burning sugar, and is finally consumed without leaving more than 0·05 per cent. of ash." *U. S.* "Readily soluble in less than its own weight of *water* and in less than three times its weight of *alcohol* (90 per cent.). An aqueous solution rotates the plane of a ray of polarized light to the right." *Br.* The powder is sometimes directed to be kept in well-stoppered vials; but Prof. Otto has shown that this direction tends to spoil rather than to preserve it. A better plan is to keep the powder in ordinary boxes.

As found in the shops, it is in the form of a fine white powder, prepared by pulverizing the crystals. A weak solution undergoes spontaneous decomposition by keeping, becoming covered with a mouldy pellicle; but, if boiled and filtered, it is said to lose this tendency. (W. H. Wood, *Chem. News*, 1871, p. 246.) It is asserted that the addition of $\frac{1}{1000}$ of salicylic acid will effectually preserve solutions of tartaric acid. In uniting with bases it has a remarkable tendency to form double salts, several of which constitute important medicines. It combines with several of the vegetable organic alkalies, so as to form salts. It is distinguished from all other acids by forming a crystalline precipitate, consisting of potassium bitartrate, when added to a neutral salt of that alkali. When associated with an excess of boric acid, it is detected with difficulty; potassa not precipitating it, even with the addition of acetic or hydrochloric acid. Its separation, however, may be effected, according to Barfoed, by means of potassium fluoride, which detaches the boric acid, to form potassium fluoborate, and renders free the tartaric acid, which then responds to the ordinary test. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 70.) Its most usual impurity is sulphuric acid, which may be detected by the solution

* *Tartaric Acid—Melting Point of Commercial Samples.* Fred. H. Smith observes that the melting point of tartaric acid is variously given at 135° C. and 170° to 180° C. He has determined the melting point of seven different commercial samples, using a corrected Yale thermometer, and obtained the following results: 162·8°; 163·5°; 159·1°; 163·5°; 163·5°; 167·5°; 162°. (*A. J. P.*, 1890, pp. 164, 165.)

affording with lead acetate a precipitate only partially soluble in nitric acid. When incinerated with mercuric oxide, it leaves no residuum, or a mere trace. The British Pharmacopœia directs that "Each gramme of tartaric acid dissolved in *water* should require for neutralization 13·3 cubic centimetres of the *volumetric solution of sodium hydroxide.* It should yield no characteristic reaction with the tests for copper, arsenium, iron, potassium, sodium, or oxalates, only the slightest reactions with the tests for calcium or sulphates, and no reaction for lead by the test described under 'Acidum Citricum.' On incineration with free access of air, it should not yield more than 0·05 per cent. of ash." "An aqueous solution (1 in 2) of the Acid mixed with a strong solution (1 in 3) of potassium acetate yields a white, crystalline precipitate which is soluble in solutions of alkalies and in mineral acids, but insoluble in acetic acid. The aqueous solution (1 in 10) of the Acid, acidulated with a few drops of hydrochloric acid, should remain unaffected by barium chloride test-solution (absence of *sulphuric acid*). Another portion of the aqueous solution (1 in 10), in which the free acid has been nearly but not entirely neutralized by ammonia, should not be affected by calcium sulphate test-solution (absence of, and difference from, *oxalic* and *uvic acids*). On supersaturating 10 C.c. of the aqueous solution (1 in 10) with ammonia water, no turbidity should be produced in the liquid by ammonium oxalate test-solution (absence of *calcium*), nor should the further addition of 1 drop of ammonium sulphide test-solution produce any dark coloration or precipitate (absence of *iron*, *lead*, *copper*, etc.). To neutralize 3·75 Gm. of Tartaric Acid should require 50 C.c. of potassium hydrate volumetric solution (each C.c. corresponding to 2 per cent. of the pure acid), phenolphtalein being used as indicator." *U. S.* Denigés gives the following modification of Mohler's test for tartaric acid. A solution of 2 Gm. of resorcinol in 1 per cent. dilute sulphuric acid is added to 20 times its volume of strong sulphuric acid. In the presence of tartaric acid this liquid gives with a few drops of the fluid to be tested a characteristic violet-red color when the mixture is heated to 115°–140°. (*Amer. Drug.*, 1896, 182.)

Tartaric acid is incompatible with salifiable bases and their carbonates; with salts of potassium, with which it produces a crystalline precipitate of bitartrate; and with the salts of calcium and lead, with which it also forms precipitates. It consists of four atoms of carbon, six of hydrogen, and six of oxygen. Of the six hydrogen atoms, however, only two are replaceable by metal, so that it is dibasic, and can form both acid and neutral salts with monad elements like potassium and sodium. Thus, cream of tartar is the acid potassium tartrate, potassium bitartrate, and so-called "soluble tartar," the neutral potassium tartrate.

Modifications of Tartaric Acid. Five distinct modifications of tartaric acid exist. Their chief physical and chemical differences are as follows:

a. Dextro-tartaric acid, or ordinary tartaric acid, forms anhydrous, hemihedral, rhombic crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the *right.* The crystals fuse at 135° C. (275° F.),—later authorities give 170° C. (338° F.),—have a sp. gr. of 1·74 to 1·75, and are readily soluble in absolute and in aqueous alcohol.

b. Lævo-tartaric acid forms anhydrous, hemihedral, rhombic crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the *left.*

c. Racemic or *para-tartaric* acid forms hydrated, holohedral, triclinic crystals of $H_2C_4H_4O_6 + H_2O$, which are optically *inactive.* The crystals have a sp. gr. of 1·69, and are soluble in five parts of cold water and with difficulty in cold alcohol. The calcium racemate is less soluble in water than calcium dextro-tartrate, and is also distinguished by its insolubility in acetic acid and in ammonium chloride solution. Racemic acid can be prepared by mixing *a* and *b* tartaric acids, and can be resolved into them by appropriate methods. Racemic acid exists naturally in small proportion in the juice of grapes growing in particular localities, and was first obtained artificially in 1853 by M. Pasteur.

d. Inactive or *meso-tartaric* acid, optically inactive, but not resolvable into *a* and *b* acids.

e. Meta-tartaric acid, produced by fusing the ordinary variety. It is deliquescent and uncrystallizable. Its solution and the solutions of its salts are converted by boiling into those of the ordinary modification.

Medical Properties. Tartaric acid, being cheaper than citric acid, forms, when dissolved in water and sweetened, an available substitute for lemonade. It may be improved by adding a drop of fresh volatile oil or a few drops of essence of lemon. Dried by a gentle heat, and then mixed with sodium bicarbonate, in the proportion of thirty-five grains of the acid to forty of the bicarbonate, it forms a good effervescing powder, the dose of which is a teaspoonful (3·75 C.c.) stirred in a tumbler of water. Tartaric acid resembles citric acid in its medical properties, but is more irritant, and taken in large amount and concentrated form

has caused fatal gastro-intestinal inflammation. It is chiefly used in medicine in the preparation of effervescing draughts.* Dose, from five to thirty grains (0·32–1·94 Gm.).

ACONITINA. Br. Aconitine.

(Ă-CŎN-Ĭ-TĪ'NĂ.)

"An alkaloid obtained from Aconite Root, and having the formula $C_{33}H_{45}NO_{12}$." *Br.*

Aconitia, Aconitina, Aconitinum, Aconitin; Aconitine, *Fr.*; Aconitin, *G.*

Formerly a process for the manufacture of aconitine was given in the U. S. and Br. Pharmacopœias, but in the 1880 revision the so-called alkaloid was dropped from the U. S. P., whilst in the late revision of the Br. Ph. the process of manufacture was omitted.†

Pure aconitine may exist in an amorphous or in a crystalline form. The official product is always crystalline, but of amorphous aconitine there are two varieties, the hydrated and the anhydrous. When the alkaloid is dried at ordinary temperature, it retains 20 (Hager) or 25 (Hottot) per cent. of water; but when dried at the temperature of the water-bath, it is anhydrous, and is then *not* soluble in 50 parts of boiling water. (Hager, *A. J. P.*, xlvii. 210.) For Hottot's process of preparing aconitine, see 15th ed. U. S. D.

Aconitine as defined by the Br. Pharmacopœia is "in colorless hexagonal prisms of the rhombic system. Melting point 372·2° to 374° F. (189° to 190° C.). Slightly above this temperature it yields acetic acid. Readily soluble in *alcohol* (90 per cent.) or *chloroform*, less readily in *ether*. Nearly insoluble in *water* and in *petroleum spirit*. An alcoholic solution of the alkaloid turns the plane of a ray of polarized light to the right. A drop of even an extremely dilute solution (not more than one-tenth per cent.) when placed on the tongue produces a persistent tingling sensation. The salts of Aconitine are crystalline. The hydrochloride melts at 300·2° F. (149° C.) and the hydrobromide at 327·2° F. (164° C.). A dilute solution of the alkaloid, even 1 part in 4000 parts of *water*, faintly acidulated with *acetic acid*, deposits a red crystalline precipitate on the addition of a few drops of *solution of potassium permanganate*." It restores the blue color of litmus reddened by acids, and neutralizes the acids, forming crystallizable salts. The solution of these salts produces a white precipitate with platinic chloride, a yellowish with auric chloride, and a yellowish brown with free iodine. Aconitine is precipitated from the solution by caustic alkalies, but not by ammonium carbonate or potassium and sodium bicarbonates. A spurious substance has sometimes been sold under the same name, which is nearly or quite inert; and at best the alkaloid is apt to be of uncertain strength as found in commerce.

Crystallized aconitine was first made known by the researches of Mr. Groves (*P. J. Tr.*, 2d ser., viii. 121), but it was elaborately studied by Duquesnel. The methods of obtaining it differ, but, according to Patrouillard (*Journ. de Pharm.*, 4e sér, xix. 151), that of Duquesnel gives much the larger yield.‡ It occurs in regular rhombic tables, sometimes having

Solution of Magnesium Tartrate as a Purgative. Owing to the relatively high price of citric acid, attempts have been made to substitute for that acid, in the solution of magnesium citrate, a cheaper acid, which might yield with magnesia an equally acceptable solution. M. E. Leger thinks he has accomplished this object by means of tartaric acid. The ordinary tartaric acid, however, will not answer, as the solution of the magnesian tartrate made with it, though at first limpid, soon becomes turbid, and most of the salt is deposited. But by employing a metatartaric acid he prepared a solution having all the desired properties. He prepares the *metatartaric acid* in the following manner.

Heating over a gentle fire, in a porcelain or preferably silver capsule, a little tartaric acid until it melts, stirring carefully from time to time, he adds successively small portions of fresh acid, taking care not to use so much as to cause the liquid to cool and solidify, and continuing to add until the vessel is two-thirds full. The heat is maintained until the mass, at first pasty and puffed up, becomes completely liquid. When bubbles are formed on the surface, the acid assumes a slight amber hue, and the desired modification has been effected. The vessel is now removed from the fire, and the contents allowed to cool until the acid can be handled without adhering to the fingers, when it is pressed into cakes, quickly cooled, and put into well-stoppered bottles.

In the preparation of the magnesian solution, three-fourths of the water to be used is poured, cold, on a mixture of the acid and magnesium carbonate (two parts of the former and one of the latter); a very brisk reaction takes place, and in less than ten minutes the solution is complete. Heat must be avoided; as otherwise the acid returns to the former state, and the salt is precipitated. When the acid has been completely modified, the solution will keep unchanged for several weeks. The cathartic action of the magnesium tartrate is, according to M. Leger, much more certain than that of the citrate, and nearly equal to that of the sulphate. The solution is without unpleasant taste. (*P. J. Tr.*, 12, 1873, p. 29; from *Répertoire de Pharm.*, Juin 25, 1873.)

† See U. S. Dispensatory, 15th and 17th editions.

‡ The method of Duquesnel is as follows. 100 parts of the powdered roots having been mixed with one part of tartaric acid, and the whole exhausted by repeated percolation with cold alcohol, the liquid is evaporated at a low temperature on a water-bath to the consistence of a fluid extract. To this distilled water is added, and the precipitated resinous and oily matters removed by filtration. The solution of aconitine tartrate is then precipitated with a slight excess of potassium bicarbonate, agitated with washed ether, and the two fluids separated with the siphon. The ethereal solution is shaken four or five times with a 10 per cent. solution of hydrochloric acid, which

the angles modified so as to look like hexagons, or else in small, short, four-sided prisms; it is anhydrous, nearly insoluble in water, insoluble in glycerin, but soluble in alcohol, ether, acetic acid, and benzin, and freely so in chloroform, inodorous, of an intensely bitter taste, followed by the characteristic tingling, not volatile at 100° C. (212° F.), and forms with most acids crystallizable salts. Juergens states that aconitine is soluble in 64 parts of absolute ether, 37 parts of absolute alcohol, 2800 parts of light petroleum of 0·670 sp. gr., 5·5 parts of chloroform or benzin, and 750 parts of water. (See *Journ. Chem. Soc.*, June, 1886.) For Dr. Squibb's physiological tests for aconitine and aconite preparations, see page 111. Its only peculiar color reaction is obtained with difficulty by dissolving in dilute phosphoric acid and evaporating; when at a certain degree of concentration a violet coloration appears.

The investigations of Dr. C. R. A. Wright upon *Aconitum napellus*, which were fully stated in the previous edition (16th ed., p. 125), have been corrected in part by later studies by Prof. Wyndham Dunstan (*Journ. Chem. Soc.*, May, 1891, April and May, 1892.) He has shown that the roots of true *Aconitum napellus* contain four alkaloids, of which one is crystallized and three are amorphous: *aconitine*, to which he gives the formula $C_{33}H_{45}NO_{12}$* instead of the formula $C_{33}H_{43}NO_{12}$ proposed by Wright; *aconine*, $C_{26}H_{41}NO_{11}$ instead of the formula $C_{26}H_{39}NO_{11}$ proposed by Wright; *napelline*, or *isoaconitine*, was shown by Dunstan (*P. J. Tr.*, 1893, 625) to have the composition $C_{33}H_{45}NO_{12}$, and is thus isomeric with aconitine. *Aconitine* melts at 188·6° C. (371·5° F.), "189°–190° C. (372·2°–374° F.)," *Br.*; and aconine when purified melts at 132° C. (269·6° F.). Dunstan was able by heating aconine together with ethyl benzoate in a sealed tube to effect the synthesis of the anhydride of aconitine. The *picraconitine* of Wright is considered by Dunstan to have been a mixture. In a later communication (*P. J. Tr.*, 1893, p. 1045) Dunstan shows that the roots of *Aconitum napellus* contain, besides the highly poisonous aconitine, an almost non-poisonous isomeride, *isaconitine*. Both furnish the same hydrolytic products,—viz., aconine and benzoic acid. Aconitine hydrobromide (melting point 163° C.), when heated in aqueous solution, is very gradually changed into the isomeric isaconitine hydrobromide (melting point 282° C.). The change is facilitated by the presence of a small quantity (1–2 per cent.) of free hydrobromic acid, but is not assisted if sufficient is present to induce hydrolysis of a large proportion of the aconitine. The hydrolysis of napelline, or aconitine, into aconine and benzoic acid is represented by the following equation:

$$C_{33}H_{45}NO_{12} + H_2O = C_{26}H_{41}NO_{11} + C_7H_6O_2.$$

Aconitum ferox was examined by Dr. Wright. In it he found chiefly the alkaloid *pseudaconitine*, $C_{36}H_{49}NO_{12}$. It crystallizes in transparent needles and sandy crystals, but is apt to separate as a varnish if not evaporated extremely slowly. It forms crystallized salts with difficulty. It can be dehydrated, forming *apo-pseudaconitine*, $C_{36}H_{47}NO_{11}$, and when saponified yields dimethyl-protocatechuic acid instead of benzoic, and a new base, *pseudaconine*, $C_{36}H_{49}NO_{12} + H_2O = C_9H_{10}O_4 + C_{27}H_{41}NO_9$. Pseudaconitine crystallizes with H_2O and melts at 104°–105° C. (220° F.). Dunstan and Carr (*Journ. Chem. Soc.*, 1897, 350) give a process for making the very poisonous alkaloid pseudaconitine, which they obtained in crystals; it dissolves in hot water, very slightly in cold water, readily in alcohol, chloroform, and acetone, less readily in ether. The products of hydrolysis, which occurs in two stages, result in the separation of *veratryl-pseudaconine*, $C_{34}H_{47}NO_{11}$, and *pseudaconine*, $C_{25}H_{39}O_8$; *veratric acid* is eliminated. *Pyropseudaconitine*, $C_{34}H_{45}NO_{10}$, an anhydride of veratryl-pseudaconine, did not appear to be poisonous. In Japanese aconite roots (species not certainly known) Wright found a larger percentage of active alkaloids than in either of the other varieties. He also considers that he has obtained here a new base, *japaconitine*, $C_{66}H_{88}N_2O_{21}$. This base on saponification splits up into benzoic acid and a base, *japaconine*, $C_{26}H_{41}NO_{10}$.

Aconitine exists in the root in combination with *aconitic acid*, $C_6H_6O_6$. Dragendorff and Spohn (*Journ. Pharm.* (5), 10, 361–368) find in *Aconitum lycoctonum* two alkaloids; *lycaconitine*, $C_{27}H_{34}N_2O_6 + 2H_2O$, which is not crystalline, nor does it yield a crystalline aurochloride or platinochloride, and *myoctonine*, $C_{27}H_{30}N_2O_8 + 5H_2O$, which is amorphous. The former alka-

takes up the alkaloids from the ethereal solution. The acid liquids are treated with calcium carbonate to saturation in order to prevent the prolonged and injurious action of the acid upon the crystallizable aconitine, the mixture is evaporated at a very gentle heat, filtered, and while still warm mixed with a solution of sodium nitrate (2 of salt to 3 of water) having the same temperature. The whole is allowed to cool slowly during several hours, and set away for several days' rest, when the crystals separate out as a crust on the bottom. (*N. R.*, 1883, p. 265; see also a paper by Williams, *Year-Book of Pharmacy*, 1886, p. 428.)

* Freund and Beck state that after making fourteen determinations of crystallized aconitine they have adopted the formula of $C_{34}H_{47}NO_{11}$ (*Ber. d. Chem. Ges.*, 1894, 433), and they defend this formula in a subsequent communication (*Ber. d. Chem. Ges.*, 1895, 192).

loid, heated with water under pressure, gives rise to two acids, a volatile one and a crystalline one, *lycoctonic acid*, $C_{17}H_{18}N_2O_7$, while two alkaloids remain dissolved, one, *lycaconine*, soluble in ether, the other soluble in chloroform, and apparently Hübschmann's acolytine.*

Medical Properties and Uses. It is practically true that the various products which are sold under the name of aconitine represent the activity of aconite, but it is well known that commercial aconitine is a very improper remedy for internal use, varying immensely in its purity, its composition, and its powers.† Two and a half grains have been taken almost with impunity, and 1-50th of a grain has nearly proved fatal; indeed, a fatal case of poisoning by half a milligramme (1-128th gr.) of pure aconitine is reported (*Journ. de Pharm. d' Anvers*, Feb. 1890). One-tenth of a milligramme (1-640th gr.) should be considered the maximum dose of the alkaloid. Tison (*Atti Dell' xi. Cong. Med. Intern.*, iii., 1894) considers this the ordinary dose of the crystallized aconitine nitrate, and repeats it at such intervals that one milligramme is taken in the twenty-four hours. As aconitine possesses no obvious advantage over the other preparations of aconite, and is so uncertain and powerful in its action, its internal use is rarely called for. Even as an external remedy, as first recommended by Dr. Turnbull, aconitine is of very limited value. It produces in the skin a sensation of heat and prickling, followed by numbness, lasting, according to the quantity applied, from two to twelve hours or more. Applied much diluted and in a minute quantity to the eye, or even to the upper eyelid, it causes contraction of the pupil, with an almost intolerable sense of heat and tingling. Dr. Turnbull employed it with benefit in *neuralgia*, *gout*, and *rheumatism*. If the alkaloid be pure, the ointment should not exceed ten grains to the ounce, and even then must be used with great caution by friction over the part affected, to be continued till the peculiar sensation above described is produced, and to be repeated three or four times, or more frequently, during the day. No good can be expected unless the sensation alluded to be experienced in a greater or less degree. Care should be taken not to apply the medicine to an abraded surface, or to a mucous membrane, for fear of poisoning.

Gen. Ch. Calyx none. *Petals* five, the highest arched. *Nectaries* two, peduncled, recurved. *Pods* three or five. *Willd.*

The plants belonging to this genus are herbaceous, with divided leaves, and violet, yellow, or white flowers, in spikes, racemes, or panicles. In the Paris Codex three species were recog-

* M. Hübschmann is said to have extracted two alkaloids from *A. lycoctonum;* one in the form of a white powder, insoluble in ether, but soluble in water and alcohol, which he names *acolytine;* the other crystallizable, very soluble in alcohol, and but slightly so in ether or water, and named by him *lycoctonine*. (*A. J. P.*, 1866, p. 376.) According to Prof. Flückiger, *lycoctonine* is in white acicular crystals, melting like aconitine in boiling water, though at a somewhat higher heat. On cooling it crystallizes only when moistened with water, when the amorphous mass is converted into tufted crystals. It leaves no water upon melting, and combines with none on crystallizing. It readily dissolves in chloroform, and upon evaporation is left as an amorphous varnish, which on the addition of a little water becomes strikingly crystalline. It is largely dissolved by sulphide of carbon, ether, alcohol, the fixed and volatile oils, amylic alcohol, and petroleum spirit; but requires 600 parts of boiling water for solution. The solution is bitter and has an alkaline reaction, and with bromine water produces fine yellow crystals; and this effect results though the solution contain only one part of the alkaloid in 30,000. Lycoctonine is an alkaloid quite distinct from aconitine and pseudaconitine, and is much less poisonous than either. (Flückiger, *P. J. Tr.*, 1870, p. 122.) Drs. Wright and Luff concluded that lycoctonine and acolytine are identical with *aconine* and *pseudaconine*, decomposition-products respectively of aconitine and pseudaconitine, but according to Dragendorff and Spohn they are really decomposition-products of two previously unnoticed alkaloids of *A. lycoctonum*, namely, *lycaconitine* and *myoctonine*. (See p. 107, also *P. J. Tr.*, viii. 169, and xv. 104.) Jacobowsky found lycaconitine to resemble curare in its physiological action, but to be of no value in practical medicine.

† Even different specimens of apparently pure crystallized aconitine made by the same chemist in the same manner vary greatly in toxic property. See K. F. Mandelin, *Archiv d. Pharm.*, 1885, xxiii.; abstracted, *P. J. Tr.*, xvi.; Bunzen and Madsen, *Trans. Internat. Congress*, Copenhagen, 1884. Lepine states that the crystallized alkaloid made from plants gathered in Switzerland is much more active than that from plants of the Vosges or of the Pyrenees. (*La Sem. Méd.*, March 30, 1892.) For method of assaying aconitine, see Dr. Dohme's paper (*Proc. A. P. A.*, 1895, 206); also *P. J. Tr.*, 1895, 860.

nized as official, *A. anthora*, *A. cammarum*, and *A. napellus;* but the French authorities unite at present with our own and the British in acknowledging only *A. napellus*. There has been much difference of opinion as to the plant originally employed by Störck. Formerly thought to be *A. napellus*, it was afterwards generally believed to be *A. neomontanum* of Willdenow, and by De Candolle was determined to be a variety of his *A. paniculatum*, designated as *störckianum*. It is probable that this species, which is not infrequent in the Alps, yields much of the aconite of commerce, as probably does also *A. lycoctonum*. But, according to Geiger, *A. neomontanum* is possessed of little acrimony; and Dr. Christison states that *A. paniculatum*, raised at Edinburgh from seeds sent by De Candolle himself, was quite destitute of that property. Neither of these, therefore, could have been Störck's plant, which is represented as extraordinarily acrid. *A. septentrionale* (Koelle), which is generally considered by botanists to be a variety of *A. lycoctonum*, although it differs somewhat in the shape of its leaves and is a native of Finland, Sweden, and other northern portions of Europe, has been elaborately studied by H. V. Rosendahl (*Arbeiten des Pharmakol. Institutes zu Dorpat*, 1895), who believes it to be a distinct species.* There are five American species of the genus, each of which is probably active, although none of them are commercial sources of the drug. Aconites used in medicine appear to be indiscriminately called by English writers *wolfsbane* or *monkshood*. Under the name of *Bish* or *Bikh*, *Nepaul aconite* is largely sold in the bazaars in India. It is probably often a mixed product of a number of Indian species, such as *A. lucidum*, *A. napellus*, and *A. palmatum*, but is chiefly derived from *A. ferox*, which grows in the Himalayas, attaining a height of from 3 to 6 feet, and having large dull-blue flowers. The tuberous roots of *A. heterophyllum*† are also met with in the bazaars. This native of the Himalayas has dull-yellow flowers veined with blue or purple.

Aconitum napellus. Linn., *Flor. Suec.*, ed. 1755, p. 168.—*A. neubergense.* De Candolle, *Prodrom.*, i. 62.—*A. variabile neubergense.* Hayne, *Darstel. u. Beschreib.*, etc., xii. 14. This is a perennial herbaceous plant, with a spindle-shaped, tapering root, seldom exceeding at top the thickness of the finger, three or four inches or more in length, brownish externally, whitish

* Rosendahl found in *A. septentrionale* three alkaloids, to which he gave the names of Lappaconitine, Septentrionaline, and Cynoctonine.

Lappaconitine, $C_{34}H_{48}N_2O_8$, occurs in crystals belonging to the hexagonal system, bitter in taste, melting point 205° C.; soluble in 126 parts of alcohol, 330 of ether, 1472 of water. Its alcoholic or ethereal solution shows a reddish-violet fluorescence. It is colored yellowish red by sulphovanadic acid, afterwards becoming green. It is a convulsant, which finally paralyzes the respiratory muscles; at the same time it lowers blood-pressure by a direct action upon the heart, and also by an influence on the vaso-motors. During the convulsion the pupils are contracted; during the paralysis they are dilated. Upon muscles, blood, lower organisms, and general protoplasm the alkaloid has no influence. It is rapidly eliminated by the urine.

Septentrionaline, $C_{31}H_{48}N_2O_9$, occurs in a white or yellowish powder of a bitter taste with a pronounced local anæsthetic influence; melting point 128·9° C. It is very soluble in alcohol and ether, and in 58 parts of water; its solutions are without fluorescence. It is colored cherry-red by fresh furfurol sulphuric acid. When given by the mouth, septentrionaline, according to Rosendahl, produces no poisonous effects; its subcutaneous or intravenous injection is followed by increased salivation, nausea, and wide-spread anæsthesia, due to an action upon the peripheral sensory nerves. If the dose has been sufficient, after the paralysis of sensibility a motor peripheral paralysis comes on, which finally invades the muscles of respiration so that the function ceases, although the heart is still working, and if artificial respiration be employed recovery occurs. The heart is said to be almost completely unaffected, excepting that the force of its contractions is augmented. Intestinal peristalsis is arrested; the pupils are not affected. Elimination is very rapid. Rosendahl asserts that the alkaloid is of great value as a substitute to curare in the physiological laboratory. The dose for curarization is *per* kilogramme of bodily weight: frogs, 0·000174 to 0·0005; dogs, 0·0070; cats, 0·0100; rabbits, 0·003000 to 0·0050; fowls, 0·0090 grammes.

Cynoctonine, $C_{36}H_{55}N_2O_{13}$, is an amorphous hygroscopic grayish powder, having a feebly bitter taste, melting at 137° C.; easily soluble in alcohol and water, soluble in 1373 parts of ether without fluorescence. If evaporated to dryness with fuming nitric acid, the residue becomes blood-red on the addition of an alcoholic solution of potash, afterwards changing to reddish brown. It is a very violent convulsant, producing also vomiting, temporary loss of superficial sensibility, followed by heightened reflexes, violent convulsions, and respiratory death. Upon the heart and blood-pressure it has very little influence. The pupils are in the advanced poisoning dilated. On the lower organisms it does not act as a poison.

† Under the name of *Utees*, *Ateés*, or *Atis*, the root of *Aconitum heterophyllum* is said to be largely used in India as an antiperiodic. It is stated that it is free from poisonous properties and is given in doses of 20 grains. The plant grows in the western Himalayas, at an elevation of from 8000 to 13,000 feet. The roots are ovoid, oblong, or conical, ½ to 1½ inches in length, $\frac{3}{10}$ to $\frac{6}{10}$ of an inch in diameter, bitter without acridity, of a light ash color. Their transverse section shows a white, farinaceous, homogeneous tunic, traversed by from 4 to 7 yellowish vascular bundles. According to Wasowicz, the root yielded $\frac{6}{100}$ of 1 per cent. of *atesine*, an amorphous, very slightly poisonous alkaloid (the same alkaloid was previously pointed out by Broughton), aconitic acid, an acid similar to tannic acid, a soft fat, cane sugar, mucilage, and pectinous substances. *Wakhma*, another Indian drug, appears to be a variety of Atis. (See *P. J. Tr.*, xvi. 86.) Jowett studied *atisine*, $C_{22}H_{33}NO_3$, as he prefers to name the alkaloid; his results show that it does not present any close analogy to the other aconite alkaloids. Prof. Cash reports that it is not toxic in small doses, and its physiological action resembles that of aconine. (*Journ. Chem. Soc.*, 1896, 1518, 1526.) He also confirms the presence of aconitic acid.

and fleshy within, and sending forth numerous long, thick, fleshy fibres. When the plant is in full growth, there are usually two roots joined together, of which the older is dark brown and supports the stem, while the younger is of a light yellowish brown, and is destined to furnish the stem of the following year, the old root decaying. The stem is erect, round, smooth, leafy, usually simple, and from two to six or even eight feet high. The leaves are alternate, petiolate, divided almost to the base, from two to four inches in diameter, deep green upon their upper surface, light green beneath, somewhat rigid, and more or less smooth and shining on both sides. Those on the lower part of the stem have long footstalks and five or seven divisions; the upper, short footstalks and three or five divisions. The divisions are wedge-form, with two or three lobes, which extend nearly or quite to the middle. The lobes are cleft or toothed, and the laciniæ or teeth are linear or linear-lanceolate and pointed. The flowers are of a dark violet-blue color, large and beautiful, and are borne at the summit of the stem upon a thick, simple, straight, erect, spike-like raceme, beneath which, in the cultivated plant, several smaller racemes arise from the axils of the upper leaves. Though without calyx, they have two small calycinal stipules, situated on the peduncle within a few lines of the flower. The petals are five, the upper helmet-shaped and beaked, nearly hemispherical, open or closed, the two lateral roundish and internally hairy, the two lower oblong-oval. They enclose two pediceled nectaries, of which the spur is capitate, and the lip bifid and revolute. The fruit consists of three, four, or five pod-like capsules.

The plant is abundant in the mountain forests of France, Switzerland, and Germany. It is also cultivated in the gardens of Europe, and has been introduced into this country as an ornamental flower. All parts of the plant are acrid and poisonous. The leaves and root are used. The leaves should be collected when the flowers begin to appear, or shortly before. After the fruit has formed, they are less efficacious. The root is much more active than the leaves; and an extract from the latter is said to have only one-twentieth of the strength of one made from the former. It should be gathered in autumn or winter after the leaves have fallen, and is not perfect until the second year. It has been mistakenly substituted for horseradish root, as a condiment, with fatal effect. The wild plant is said to be more active than the cultivated. (*Schroff.*) Prof. Wm. Procter found the roots of the plant cultivated in this country richer in the active alkaline principle than the imported roots, having obtained as much as 0·85 per cent. from the former. (*Proc. A. P. A.*, 1860.)*

The aconite root is brought into market in packages or bales, originally, in general, either from the continent of Europe or from India. It is of variable quality; some parcels being unobjectionable, while others contain a considerable proportion of inert or defective roots. Among these roots that of *Imperatoria ostruthium* has been expressly noted. (*P. J. Tr.*, vii. 749.) The best test is the taste; roots should be rejected which have not in a fair degree the characteristic properties in this respect described below, especially the sensation of numbness and tingling on the tongue, lips, and fauces.

Nepaul aconite is composed of elongated, conical, tuberous, or nearly cylindrical roots, 3 to 4 inches long, ½ to 1¾ inches in diameter at the base; unbranched; often abruptly broken off below; more or less flattened; shrivelled chiefly in a longitudinal direction, and sparsely marked with the scars of rootlets. *Japanese aconite* has also been largely sold in London.† It consists of plump, oblong or ovoid, dark grayish or blackish tubers, from half an inch to an inch in length, and ⅛ to ⅖ of an inch in diameter.

Properties. The *fresh leaves* have a faint narcotic odor, most sensible when they are rubbed. Their taste is at first bitterish and herbaceous, afterwards burning and acrid, with a

* The recent studies of P. W. Squire seem to show that at this period the root is the most active. So far, however, as concerns the whole plant, the practical difficulty is that the root of *A. paniculatum* cannot be distinguished from that of *A. napellus*, except by taste: so that the custom which seems to prevail of gathering the root about the flowering period is probably well founded. The plant is being cultivated to some extent for medicinal purposes in England, but much of the stock is of doubtful nature, owing to the extraordinary tendency of *A. napellus* to hybridize with other species and to alter under cultivation. (See *P. J. Tr.*, xix.) For C. C. Keller's tests for aconite root and leaves, see *Proc. A. P. A.*, 1895, 539.

† *Japanese Aconite.*—Seven varieties of aconite tubers are said by Dr. Langaard to be found in the Japanese drug-stores, usually preserved in vinegar or child's urine, or by drying. The botanical source of these aconite roots is not accurately determined, but they are probably, at least in part, yielded by *A. japonicum*, Thunb., and *A. fischeri*, Reich., believed by many botanists to be respectively identical with *A. lycoctonum*, Linn., and *A. chinense*, Sieb. Several alkaloids have been separated; of these, *japaconitine* is said to be the most poisonous of the known aconite alkaloids. (See *P. J. Tr.*, 3 ser., xi. 149, 1021.) Dr. O. Lezius (*Inaug. Diss.*, Dorpat, 1890) asserts that the active principle of Japanese aconite is true crystallizable aconitine, and in an elaborate physiological study Alfred E. Bradley found the physiological activity of *A. fischeri* very similar to that of *A. napellus*. (*Weekly Med. Rev.*, April, 1888.)

feeling of numbness and tingling on the inside of the lips, tongue, and fauces, which is very durable, lasting sometimes many hours. When long chewed, they inflame the tongue. The *dried leaves* have a similar taste, but the acrid impression commences later. Their sensible properties and medicinal activity are impaired by long keeping. They should be of a green color, and free from mustiness. The *root* has a feeble earthy smell. Though sweetish at first, it has afterwards the same effect as the leaves upon the mouth and fauces. It shrinks much in drying, and becomes darker, but does not lose its acrimony. Those parcels, whether of leaves or roots, should always be rejected which are destitute of this property. As found in commerce, the aconite root is described as being "from 10 to 20 Mm. (three-eighths to three-quarters of an inch) thick at the crown; conically contracted below; from 50 to 75 Mm. (two to three inches) long, with scars or fragments of radicles; dark brown externally; whitish internally; with a rather thick bark, the central axis about seven-rayed; without odor; taste at first sweetish, soon becoming acrid, and producing a sensation of tingling and numbness, which lasts for some time." *U. S.* "The transverse section exhibits a thick parenchymatous cortex and a large stellate pith with about seven projecting angles; the groups of vessels are small and few in number." *Br.* The seeds also are acrid. The British Pharmacopœia formerly recognized the flowering tops of the Aconite (*Aconiti Folia*). To be effective they should be collected just as the flowers are beginning to expand, at which time they are richest in alkaloid. The dried leaves are stated to contain about 0·3 per cent. and the flower-buds about 0·4 per cent. of aconitine. For an account of the chemistry of aconite, see *Aconitina*, page 106.

Medical Properties and Uses. Aconite was well known to the ancients as a powerful poison, but was first employed as a medicine by Baron Störck, of Vienna, whose experiments with it were published in the year 1762. In moderate doses, it produces warmth in the stomach and sometimes nausea, general warmth of the body, numbness and tingling in the lips and fingers, muscular weakness, diminished force and frequency of the pulse, and diminished frequency of respiration. From larger doses all these effects are experienced in an increased degree. The stomach is more nauseated; the numbness and tingling extend over the body; headache, vertigo, and dimness of vision occur; the patient complains occasionally of severe neuralgic pains; the pulse, respiration, and muscular strength are greatly reduced; and a state of general prostration may be induced, from which the patient may not quite recover in less than two or three days. The effects of remedial doses are felt in twenty or thirty minutes, are at their height in an hour or two, and continue with little abatement from three to five hours. In poisonous doses, besides the characteristic tingling in the mouth and elsewhere, aconite occasions burning heat of the œsophagus and stomach, thirst, violent nausea, vomiting and purging, severe gastric and intestinal spasms, headache, dimness of vision, with contracted or expanded pupils, numbness or paralysis of the limbs, diminished sensibility in general, stiffness or spasm of the muscles, great prostration, pallid countenance, cold extremities, an extremely feeble pulse, and death in a few hours, sometimes preceded by delirium, stupor, or convulsions. All these effects are not experienced in every case; but there is no one of them which has not been recorded as having occurred in one or more instances. The proper treatment of aconite poisoning consists in the maintenance of absolute rest in a position horizontal, or with the head lower than the feet; the evacuation of the stomach by the siphon tube or stomach-pump, if free vomiting do not occur; the administration of stimulus, and the use of external heat to keep up the bodily temperature. Whiskey or brandy should be given freely in a concentrated form by the mouth and rectum; when the symptoms are very urgent, it may be injected under the skin. The chief reliance in any case, however, must be on the tincture of digitalis aided by strychnine, the two remedies being given hypodermically, but separately, in large doses. Ammonia may be employed carefully. We have known life to be apparently saved by laudanum given in drachm doses. Fall of the bodily temperature must be met by external heat.

The symptoms produced by aconite are chiefly due to its action upon the circulation and the nervous system. It is a direct and powerful depressant of the heart, if in sufficient amount completely paralyzing the cardiac muscle. The lowering of the force of the circulation is certainly in large part due to this action; but it is probable, although not proved, that it also paralyzes the vaso-motor system. Upon the cerebrum the drug exerts very little if any direct influence. Upon the peripheral sensory nerves it acts as a powerful depressant, thereby causing the characteristic tingling and numbness of aconite poisoning. The influence upon the spinal marrow seems to be less pronounced than that upon the sensory nerves; but, if in sufficient amount, the poison depresses the motor centres of the cord. To this, and not to any effect

upon the motor trunks or the muscles, is due the loss of reflex activity and of voluntary power caused by toxic doses.

As an internal remedy, aconite is very valuable in *sthenic fever* from any cause; when the condition is *asthenic* it should never be administered. It is also useful in some cases for the purpose of benumbing sensitive nerves: thus, it will sometimes arrest the *vomiting of pregnancy*, and has often been used with excellent results in *rheumatic neuralgia*. To obtain such effects it must be given boldly. Applied locally to a sensitive or painful part, it is very efficient, owing to its being brought in a concentrated state into contact with the irritated nerves. It is a favorite application in *neuralgias*, and will probably achieve good more often than any other narcotic local remedy. Applied to the skin, aconite occasions heat and prickling or tingling, followed by numbness, and, if in contact with a wound, produces its peculiar constitutional effects. Applied to the eye, it causes decided contraction of the pupil.* The dose of the extract of the leaves is from half a grain to a grain (0·03–0·065 Gm.), of the tincture of leaves twenty or thirty drops (1·25–1·9 C.c.), to be repeated twice or three times a day, and gradually increased till the effects of the medicine are experienced. The preparation now almost exclusively employed is the tincture of the root, *Tinctura Aconiti. U. S.* Of this, from 2 to 5 drops (0·12–0·3 C.c) may be given every two to four hours until its effects become obvious. It is very important to distinguish between the tincture of the leaves formerly official and still used and the much stronger tincture of the root just referred to. Few patients will bear at first more than four minims of the latter. Very properly, we think, the tincture of the leaves was abandoned at the revision of the U. S. P. 1860. Aconite may be used externally in the form of the saturated tincture of the root, of extract mixed with lard, of a plaster or liniment, or of aconitine ointment. The tincture may be applied by means of a soft piece of sponge on the end of a stick.

"The prepared internal fat of the abdomen of Sus Scrofa, Linné (class, Mammalia; order, Pachydermata), purified by washing with water, melting, and straining. Lard should be kept in well-closed vessels impervious to fat, and in a cool place." *U. S.* "The purified fat of the hog, Sus scrofa, Linn." *Br.*

Adeps Suillus, *P. G.;* Axungia Porci, s. Porcina, Axungia, *Lat.;* Prepared Lard, Hog's Lard. *Eng.;* Axonge, Graisse, Graisse de Porc, Saindoux, *Fr.;* Schweineschmalz, *G.;* Grasso di Porco, Lardo, *It.;* Manteca de Puerco, Lardo, *Sp.*

Preparation. Lard is the prepared fat of the hog. The Br. Pharmacopœia gives a process for its preparation; but in this country it is generally purchased by the druggists already prepared. The adipose matter of the omentum and mesentery, and that around the kidneys, are usually employed; though the subcutaneous fat is said to afford lard of a firmer consistence. In the crude state it contains membranes and vessels, and is more or less contaminated with blood, from all which it must be freed before it can be fit for use. For this purpose, the fat, having been deprived of membranous matter as far as possible by the hand, is cut into pieces, washed with water till the liquor ceases to be colored, and then, after carefully separating the water, it is melted in a copper or iron vessel, over a slow fire.† The heat is continued till all the moisture is evaporated, which may be known by the transparency of the melted fat, and the absence of crepitation when a small portion of it is thrown into the fire. Care should

* *Squibb's Test for Aconite and its Preparations.*—In the absence of any reliable chemical tests for aconitine, Dr. Squibb suggests that a fluidrachm of a solution of the various preparations be taken into the anterior part of the mouth (after the latter has been thoroughly rinsed) and held there for one minute by the watch, and then discharged. The peculiar numbing sensation should be experienced within fifteen minutes, and it should continue for fifteen or thirty minutes. Tested in this way, he found the commercial aconitines, in solution of the strength of $\frac{1}{800}$ grain in 1 fluidrachm of water, to have the following relative strengths: 1 grain of good powdered aconite root is equal to 1 grain of ordinary commercial aconitine, $\frac{1}{8}$ grain of Merck's ordinary aconitine, $\frac{1}{33}$ grain of Merck's pseudaconitine, $\frac{1}{111}$ grain of Duquesnel's aconitine crystallized (really aconitine nitrate). He also found by this approximate method that 1 grain of powdered aconite root was equivalent to 1 minim of fluid extract, $\frac{1}{6}$ grain of alcoholic extract of aconite root, 2·66 minims of U. S. P. tincture of aconite root, 8·43 minims of British tincture of the root, 11·8 minims of German tincture of the root, 1·5 minims of Fleming's tincture, 9 grains of powdered aconite leaf, 1·5 grains of alcoholic extract of dried aconite leaf, 1 grain of Allen's English extract of fresh plant, and 72 minims of tincture of aconite leaf.

† Prof. Procter recommends the following method of operating. After careful removal of the membranes and adhering flesh, the crude lard is to be cut into small pieces, malaxated with successive portions of cold water until this remains clear, and then heated moderately, in a tinned vessel, until the melted fat becomes perfectly clear and anhydrous. Lastly, it is to be strained into earthen pots, being occasionally stirred as it cools; and the pots should be securely covered with waxed or varnished paper, and kept in a cool, dry cellar. (*A. J. P.*, xxxv. 114.)

be taken that the heat be not too great, as otherwise the lard might be partially decomposed, acquire a yellow color, and become acrid. This may be guarded against by using a water-bath in melting the lard. The process is completed by straining the liquid through linen, and pouring it into suitable vessels, in which it concretes upon cooling. To render it, however, perfectly free from particles of membrane and tissue, which are often the cause of rancidity and unfit lard for its finer and more permanent uses, Mr. Ed. Smith, of Torquay, insists on the necessity of filtering the lard through paper, after freeing it from its coarser impurities by straining through linen. By this author it is recommended that the process of purification should be completed by remelting the lard, by means of a water-bath, and then carefully filtering it through paper in a warm closet. Lard may be rendered quite inodorous by melting it, when fresh, by means of a salt-water bath, adding a little alum or common salt, continuing the heat till a scum rises which is to be skimmed off, and, after the lard has concreted, separating the saline matter by washing it thoroughly with water. For a particular account of the process, see *A. J. P.*, xxviii. 176.

The following is the process of the British Pharmacopœia for preparing lard. "From the perfectly fresh fat of the abdomen of the hog remove as much of the external membranes as possible; suspend the fat so that it shall be freely exposed to the air for some hours; cut it into small pieces; reduce these to a uniform mass in which the membranous vesicles are completely broken, by beating in a mortar or by some similar process; put the mass thus produced into a vessel surrounded by warm water; heat to a temperature not exceeding 135° F. (57·2° C.) until the fat has melted and separated from the membranous matter; strain." The process of the British Pharmacopœia differs from that formerly used, and is modelled upon the suggestions of Prof. Redwood, that the use of water be especially avoided, and that the selected fat be exposed freely to air and light before rendering. (*P. J. Tr.*, 1883, p. 364; also *Ephemeris*, 1884, p. 504.)

Lard, as offered for sale, often contains common salt, which renders it unfit for pharmaceutical purposes. This may be detected, when the quantity is insufficient to be sensible to the taste, by means of silver nitrate, which will produce a precipitate of silver chloride with water in which the salted lard has been boiled, after cooling and filtration. To free it from this impurity, it may be melted with twice its weight of boiling water, the mixture well agitated and set aside to cool, and the fat then separated. Lard is sometimes adulterated with water, starch, and a small proportion of alum and quicklime, which render it whiter, but unfit for medical use. But by far the most common adulteration of lard in recent years is through the use of cotton-seed oil. Indeed, some specimens of lard consist almost wholly of mixtures of stearin and cotton-seed oil. Lard of this kind can easily be detected by the disagreeable and characteristic odor of cotton-seed oil which is evolved when it is heated. For Taylor's method of differentiation, see *Nat. Drug.*, 1892, p. 103. Crookes (*Analyst*, 1893, p. 221) gives the following very delicate modification of Milliau's test. Pure white filtering paper is first moistened with 12 per cent. solution of silver nitrate and held over a small sample of the lard, which is gradually heated in an oil-bath to 115·5° C. (240° F.), when, if even less than 1 per cent. of cotton-seed oil is present, the paper will turn light brown to nearly black. Pure fresh lard does not affect the paper. Schweitzer and Lungwitz propose as a test phosphomolybdic acid, which gives no coloration with a solution of pure lard in chloroform or ether, but a blue color with cotton-seed oil. Jean states that vegetable oils added to lard increase the density, raise the iodine number, lower the melting point, the standard of fatty acids, and Koettsdorffer's number, and diminish the optical deviation. (*Chem. News*, 1896, p. 83.)

Properties. Lard is "a soft, white, unctuous solid, having a faint odor free from rancidity, and a bland taste. Insoluble in water; very slightly soluble in alcohol; readily soluble in ether, chloroform, carbon disulphide, or benzin. Specific gravity, about 0·932 at 15° C. (59° F.). It melts at 38° to 40° C. (100·4° to 104° F.) to a perfectly clear liquid, which is colorless in thin layers, and which should not separate an aqueous layer. At or below 30° C. (86° F.), it is a soft solid. Distilled Water boiled with Lard should not acquire an alkaline reaction (absence of *alkalies*), nor should another portion be colored blue by iodine test-solution (absence of *starch*). A portion of the water, when filtered, acidulated with nitric acid, and treated with silver nitrate test-solution, should not yield a white precipitate soluble in ammonia (absence of *chlorides*). If 10 Gm. of Lard be dissolved in chloroform, and the solution mixed with 10 C.c. of alcohol and 1 drop of phenolphtalein test-solution, it should not require more than 0·2 C.c. of potassium hydrate normal volumetric solution to produce a pink tint after strong shaking (limit of *free fatty acids*). If 5 C.c. of melted and filtered Lard be, while

warm, intimately mixed, by agitation, in a test-tube, with 5 C.c. of an alcoholic solution of silver nitrate (made by dissolving 0·1 Gm. of silver nitrate in 10 C.c. of deodorized alcohol and adding 2 drops of nitric acid), and the mixture then heated for five minutes in a water-bath, the liquid fat should not acquire a reddish or brown color, nor should any dark color be produced at the line of contact of the two liquids (absence of more than about 5 per cent. of *cotton-seed fats*)." *U. S.* "Is neutral to *litmus;* dissolves entirely in *ether*. It should yield no reaction with the tests for sodium, chlorides, or starch. If a solution of 0·05 gramme of *silver nitrate* in 5 cubic centimetres of *alcohol* (90 per cent.), to which a drop of *nitric acid* has been added, be heated with 5 cubic centimetres of melted Lard on a water-bath for 5 minutes and then vigorously shaken, the fatty layer which separates on standing should not darken in color (absence of cotton-seed oil). 10 grammes of Lard dissolved in a mixture of equal volumes of *chloroform* and *alcohol* (90 per cent.), two drops of *solution of phenol-phthalein* being added, should not require more than 0·2 cubic centimetre of the *volumetric solution of sodium hydroxide* to produce a permanent red color (limit of acidity)." *Br.* When melted, it readily unites with wax and resins. Like most animal fats and oils, it consists of stearin, palmitin, and olein; its consistence, when pure, depending largely upon the relative proportions of these principles; olein, being the liquid principle, can readily be separated from the other two by subjecting lard in cold weather to strong pressure, when the *olein* (*lard oil*) is pressed out, the solid residue (*stearin*) being used for various purposes, more particularly the manufacture of candles. Olein may also be separated by means of boiling alcohol, which, on cooling, deposits the concrete principles of the lard. Lard oil (see *Oleum Adipis*) is extensively employed for burning in lamps, as a lubricant, and for greasing wool. Vast quantities of it are prepared in Cincinnati, Chicago, and other centres of the pork-slaughtering industry. It is a very large article of export, the amount exported in 1896 having been 509,534,256 lbs., valued at $33,589,856, and in 1897, 568,315,640 lbs., valued at $29,126,485.

Exposed to the air, lard absorbs oxygen and becomes rancid. It should, therefore, be kept in well-closed vessels, or procured fresh when wanted for use. In the rancid state, it irritates the skin, and sometimes exercises an injurious reaction on substances mixed with it. Rancidity in lard and other fats is prevented by digesting them with benzoin or poplar buds, and rancid lard may often be greatly improved by washing it with lime water. (See *Unguenta.*) Lard even when fresh is slightly acid, as was proved by Dieterich, *Arch. de Pharm.*, 1887.

Medical Properties and Uses. Lard is emollient, and is occasionally employed by itself in frictions, or in connection with poultices to preserve their soft consistence; but its chief use is in pharmacy as an ingredient of ointments and cerates.

ADEPS BENZOINATUS. U. S. (Br.) Benzoinated Lard.

(Ă'DĔPS BĔN-ZŌ-Ī-NĀ'TŬS.)

Adeps Benzoatus, *Br.;* Benzoated Lard; Unguentum Benzoini, *U. S.* 1870; Axungia Balsamica, s. Benzoinata, s. Benzoata; Ointment of Benzoin, *E.;* Axonge (Graisse) benzoinée (balsamique), *Fr.;* Benzoinirtes Schmalz, *G.*

Preparation. "Lard, *one thousand grammes* [or 35 ounces av., 120 grains]; Benzoin, in coarse powder, *twenty grammes* [or 308 grains]. Melt the Lard by means of a water-bath. Tie the Benzoin loosely in a piece of coarse muslin, suspend it in the melted Lard, and, stirring frequently, continue the heat for two hours, covering the vessel and not allowing the temperature to rise above 60° C. (140° F.). Lastly, having removed the Benzoin, strain the Lard, and stir occasionally while it cools. When Benzoinated Lard is to be kept or used during warm weather, 5 per cent. (or more, if necessary) of the Lard should be replaced by White Wax." *U. S.*

"Lard, 1 *pound* (Imperial) or 500 grammes; Benzoin, in powder, 210 *grains* (Imperial) or 15 grammes. Melt the Lard on a water-bath; add the Benzoin; continue the application of heat for two hours, frequently stirring; remove the residue of the Benzoin by straining; stir the Benzoated Lard until cold." *Br.* That the balsamic or resinous principles in certain substances like benzoin exercise a valuable function in preserving fats has been proved by abundant experience. It has been shown that when made, as originally suggested by Doliber and directed in the U. S. Pharmacopœia of 1870, by incorporating the tincture with lard, ointment of benzoin was irritating to the skin in certain diseases: hence the return to the old process of digesting the benzoin in lard, kept at a temperature of 60° C. (140° F.). The present U. S. formula does not differ materially from the British, except in the directions to enclose the benzoin in a muslin bag and the regulation of the temperature; the first improvement has for its object the prevention of the hard cake of benzoin, which otherwise collects at the bottom of the water-

bath, and is apt to be imperfectly acted upon. A much pleasanter and more agreeable product is insured by heeding the U. S. directions as to limiting the temperature, a high heat volatilizing the odorous principles and communicating an empyreumatic odor.

ADEPS LANÆ. Br. Wool-Fat.

(Ā'DĔPS LĀ'NÆ.)

"The purified cholesterin-fat of sheep's wool." *Br.*

The British Pharmacopœia recognizes both wool-fat and hydrous wool-fat. Wool-fat is "A yellowish, tenacious, unctuous substance; almost inodorous; melting point varies from 104° to 112° F. (40° to 44·4° C.); readily soluble in *ether* or in *chloroform*, sparingly soluble in *alcohol* (90 per cent.). 1 gramme should dissolve almost completely in 75 cubic centimetres of boiling *alcohol* (90 per cent.), the greater part separating in flocks on cooling. When incinerated with free access of air, it leaves not more than 0·3 per cent. of ash, which should not be alkaline to *litmus*. 10 grammes dissolved in 25 cubic centimetres of *ether*, two drops of *solution of phenol-phthalein* being added, should not require more than 0·1 cubic centimetre of *volumetric solution of sodium hydroxide* to produce a permanent red coloration (limit of acidity). The solution in *chloroform* poured gently over the surface of *sulphuric acid* acquires a purple-red color. Heated with *solution of sodium hydroxide*, no ammoniacal odor should be evolved (absence of nitrogenous animal matter)." *Br.* (See next article.)

ADEPS LANÆ HYDROSUS. U. S., Br. Hydrous Wool-Fat.

(Ā'DĔPS LĀ'NÆ HĪ·DRŌ'SUS.)

"The purified fat of the wool of sheep (Ovis Aries, Linné; class, Mammalia; order, Ruminantia), mixed with not more than 30 per cent. of water." *U. S.*

Lanoline; Lanolin, *G.*

"Wool-Fat, 7 *ounces* (Imperial) or 140 grammes; Distilled Water, 3 *fl. ounces* (Imp. meas.) or 60 cubic centimetres. Place the Wool-Fat in a warm mortar; add the Distilled Water gradually and with constant trituration." *Br.*

The two Pharmacopœias differ in that whilst the U. S. P. recognizes only hydrous wool-fat and gives no formula for its preparation, the Br. P. recognizes wool-fat and gives the preceding directions for preparing hydrous wool-fat. Both the anhydrous and hydrous should be official in the U. S. Pharmacopœia.

Preparation. The wool of sheep contains on the average about 45 per cent. of its weight of fat, which must be removed before the wool can be used in the manufacture of woollen tissues. The crude fat has been termed *œsipus* and *œsipum*. This fat, to which the name of lanolin has been given, is a mixture of ethers of *cholesterin*, $C_{26}H_{43}(OH)$, with the several fatty acids contained in ordinary fats. Darmstaedter and Lifscheitz obtained from the alkaline washings of partially saponified lanolin two unsaturated alcohols, $C_{10}H_{20}O$ and $C_{11}H_{22}O$, both being colorless, odorless, and tasteless powders; *lanolin alcohol*, $C_{12}H_{24}O$, also a colorless, odorless powder, was isolated by G. Marchetti (*Ber. d. Chem. Ges.*, 1895, No. 19); by the action of chromic acid the latter is converted into lanolinic acid, $C_{12}H_{22}O_3$, a white, crystalline powder (*P. J. Tr.*, 1895, p. 75). Lanolin was originally recommended by Dr. Oscar Liebreich, and may be readily procured from the washings of the wool by a process which has been patented by him, or it may be obtained by treating the wool with petroleum benzin and distilling off the benzin. The objection to the latter process is the difficulty of getting rid of the benzin odor. Liebreich's patented process is as follows. The fresh undecomposed waste liquor or lye is passed through a centrifugal machine, in which the dirt and the fat are separated from each other, while the cleansed soap liquor is continually drawn off by means of a pipe and led directly into the vat which serves for the acidulation. The raw lanolin thus obtained is thoroughly kneaded by suitable machinery, in cold flowing water until the water which flows off is as clear as the water which flows in. The raw lanolin is then heated with water, whereby it is split up into water and fat. The latter is skimmed off from the surface and cooled, and for further purification it can be treated in the centrifugal machine in a melted condition, or it can be dissolved in ether, ethylated or methylated spirits, or other solvents, and the solution can be separated from the residue by filtration or other means. The solvents can be recovered by treatment in suitable stills. After the fat has been cleaned as above stated, it is thoroughly kneaded with water for a long time, and a perfectly white neutral colorless ointment is obtained. From the deposit in the lowest part of the centrifugal machine a further portion of

lanolin can be obtained by stirring the same up with clean or salt water and again treating it in the centrifugal machine, or extracting it, either in a wet or a dry condition, by means of a solvent, after which it is treated as above.

Instead of producing lanolin from wool-washing water it may be obtained from commercial wool-fat by stirring this wool-fat together with water containing sodium carbonate, caustic soda, or an alkali, or a mixture of these to form a thin milky solution, which is treated in the manner above described.

"A yellowish-white or nearly white, ointment-like mass, having a faint, peculiar odor. Insoluble in water, but miscible with twice its weight of the latter, without losing its ointment-like character. With ether or chloroform it yields turbid solutions which are neutral to litmus paper. Hydrous Wool-Fat melts at about 40° C. (104° F.). When heated on a water-bath, it finally leaves a residue amounting to not less than 70 per cent., which is transparent while melted, and, when cold, appears as a yellow, tough, unctuous mass, completely soluble in ether or chloroform, and only partially soluble in alcohol. A solution (1 in 50) of a portion of this mass in chloroform, when poured on the surface of concentrated sulphuric acid, gradually develops a deep brown color at the line of contact of the two layers. When a portion of this mass is ignited, it should leave not more than 0·3 per cent. of ash, which should not have an alkaline reaction on litmus (absence of *alkalies*). If 2 Gm. of the same mass are dissolved in 10 C.c. of ether, and mixed with 2 drops of phenolphtalein test-solution, a colorless liquid results (absence of *free alkalies*), which should be decidedly reddened by 1 drop of potassium hydrate normal volumetric solution (absence of *free fatty acids*). If 10 Gm. of Hydrous Wool-Fat be heated, together with 50 C.c. of water, on a water-bath, until the fat is melted, there should result an upper, translucent and light yellow, fatty layer, and a lower, clear, aqueous layer, which latter should not yield glycerin upon evaporation, and when a portion of it is heated with some potassium or sodium hydrate test-solution, it should not emit vapors of *ammonia*." *U. S.* "10 grammes heated on a water-bath, with stirring, until the weight is constant, should yield not less than 7 grammes of residue, which should answer to the tests for Wool-Fat." *Br.*

Medical Properties and Uses. It has been claimed for lanolin that it passes through the skin much more readily than do ordinary fatty substances. According to Patschkowski, half an hour after inunction of a mixture of lanolin and potassium iodide, iodine can be recovered from the urine, whilst the official ointment yields a negative result. This has been confirmed by Kaspar; but Ritter and Pfeiffer in a long series of experiments were unable to perceive that lanolin had any superiority over other fats in promoting absorption. Further, when it is remembered that lanolin is a sebaceous secretion, largely composed of cholesterin and allied substances, and not intended by nature to be absorbed, but to grease and soften the fibres of the wool, the possession by it of the property of aiding absorption through the skin becomes very doubtful. On the other hand, it is undoubtedly soothing to the skin, and often makes an excellent basis for ointments expected to act especially upon the skin. Lanolin has been used as a basis for suppositories and bougies. (*Amer. Drug.*, 1898, 35.)

ÆTHER. U. S., Br. Ether.

See page 118.

ÆTHER ACETICUS. U. S., Br. Acetic Ether. [Acetate of Ethyl.]

$C_2H_5, C_2H_3O_2$; 87·8. (Æ'THĘR Ą-ÇĔT'Ī-CŬS.) $C_2H_5C_2H_3O_2$; 88.

Naphtha Acete; Ethyl Acetate; Ether acétique, Naphte acétique, *Fr.*; Essigaether, Essignaphtha, *G.*

"A liquid composed of about 98·5 per cent., by weight, of Ethyl Acetate [$C_2H_5C_2H_3O_2$ = 87·8], and about 1·5 per cent. of Alcohol containing a little water. It should be kept in well-stoppered bottles, in a cool and dark place, remote from lights or fire." *U. S.* "An ethereal liquid consisting of ethyl acetate, $CH_3.COO(C_2H_5)$, together with unimportant amounts of ethylic alcohol or other substances, obtained by distillation from a mixture of ethylic alcohol, sulphuric acid, and dried sodium acetate, digestion of the distillate with dried potassium carbonate, and subsequent separation, by distillation, of the portion boiling between 165° and 172° F. (73·9° and 77·8° C.)." *Br.*

Preparation. A process for preparing this ether will be found in a former British Pharmacopœia (1885). It is a modification of the process recommended by W. I. Clark (*P. J. Tr.*, 1883, p. 777), and is as follows: "Take of Rectified Spirit, 32½ fluidounces [Imp. meas.]; Sulphuric Acid, 32½ fluidounces [Imp. meas.]; Acetate of Sodium, 40 ounces [av.];

Carbonate of Potassium, freshly dried, 6 ounces [av.]. To the spirit slowly add the acid, keeping the fluid cool, and, the product being cold, add the acetate, mixing thoroughly. Distil forty-five fluidounces [Imp. meas.]. Digest the distillate with the carbonate of potassium for three days in a stoppered bottle. Separate the ethereal fluid, and again distil until all but about four fluidounces have passed over. Preserve the resulting acetic ether in a well-closed bottle and in a cool place." *Br.* In addition to this method, acetic ether may be made by several processes, the chief of which are the following. 1. Mix 100 parts of alcohol (sp. gr. 0·83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a receiver, kept cold with wet cloths. 2. Distil to dryness a mixture of three parts of sodium acetate, three of alcohol, and two of sulphuric acid, mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil two parts of effloresced lead acetate with one part of alcohol, and a little more than one part of sulphuric acid. In the last two processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed. J. A. Pabst has devised a process for acetic ether in imitation of that for the preparation of common ether. 50 C.c. of sulphuric acid and the same quantity of alcohol are heated together in a retort to 140° C. (284° F.), and then a mixture of one liter of 96 per cent. alcohol and one liter of acetic acid (93 per cent.) is allowed to flow in slowly. At first some ethyl ether goes over, and then a liquid which contains, with considerable uniformity, 85 per cent. acetic ether. The reaction takes place between 130° C. (266° F.) and 135° C. (275° F.); at 145° C. (293° F.) some sulphurous acid is produced. The yield is about 1350 grammes, or 78 per cent., which is 90 per cent. of the theoretical amount. With reference to the solubility of acetic ether in saturated calcium chloride solution, it is to be remarked that pure acetic ether is not dissolved, although it is if mixed with 90 per cent. alcohol. One volume acetic ether, one volume alcohol, and two volumes calcium chloride solution give a homogeneous liquid. The methyl acetic ether can be prepared exactly as the ethyl compound, but in the attempt to prepare the amyl acetic ether in an analogous manner side reactions were found to interfere. In order to study the proportional power of combination possessed by the two alcohols, Mr. Pabst allowed a mixture of 100 C.c. methyl alcohol and 100 C.c. acetic acid to flow into a mixture of 50 C.c. sulphuric acid and 50 C.c. ethyl alcohol. The first distillates contained essentially methyl acetate and the latter pure ethyl acetate. In the flask were found remaining nearly equal amounts of sulphuric and ethyl sulphuric acids, and in addition alcohol, acetic acid, and some residual ethyl acetate. (*Bull. Soc. Chim.*, vol. xxxiii. pp. 350, 351; *A. J. P.*, 1880.)

The United States Pharmacopœia describes it as "a transparent, colorless liquid, of a fragrant and refreshing, slightly acetous odor, and a peculiar acetous and burning taste. Specific gravity, 0·893 to 0·895 at 15° C. (59° F.). Boiling point, about 76° C. (168·8° F.). Soluble in about 8 parts of water at 15° C. (59° F.); miscible, in all proportions, with alcohol, ether, fixed and volatile oils. Acetic Ether is readily volatilized, even at a low temperature. It is inflammable, burning with a yellowish flame and an acetous odor. It is neutral to litmus paper. When evaporated in a capsule, Acetic Ether should leave *no residue*. If a portion be allowed to evaporate spontaneously from clean, odorless blotting paper, the final odor should not resemble that of pine-apples (absence of *butylic* and *amylic derivatives*). When 25 C.c. of Acetic Ether are shaken, in a graduated tube, with 25 C.c. of water just previously saturated with the Ether, upon separation, the ethereal layer should not measure less than 24·5 C.c. (absence of an *undue proportion of alcohol or water*). When a small portion of the Ether is carefully poured upon some concentrated sulphuric acid, no dark ring should be developed at the point of contact of the two layers (absence of *readily carbonizable, organic impurities*)." *U. S.* "1 part by weight dissolves in not less than 10 parts of cold *water*. Specific gravity 0·900 to 0·905. It should have no action on *solution of litmus*. It is not colored when mixed with an equal volume of *sulphuric acid* (absence of organic impurities). Filter-paper moistened with Acetic Ether should remain odorless when the liquid has evaporated." *Br.*

Medical Properties and Uses. Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. Its action upon the system is probably very similar to that of ether; but as it is less volatile it is less rapidly absorbed and eliminated, and consequently is much less prompt and fugacious in its influence than is ether. It is locally irritating. It has been found by Dr. H. C. Wood to be capable of being used as an anæsthetic, but to be too slow in its action for practical purposes. The dose by the mouth is from fifteen to fifty drops (0·9–3·08 C.c.), sufficiently diluted with water. It is sometimes employed externally, by friction, as a resolvent, and for *rheumatic pains*.

ÆTHER. U. S., Br. Ether.

(Æ'THĘR—ē'ther.)

"A liquid composed of about 96 per cent., by weight, of absolute Ether or Ethyl Oxide $[(C_2H_5)_2O = 73{\cdot}84]$, and about 4 per cent. of Alcohol containing a little Water. Ether should be kept in well-stoppered containers, preferably in tin cans, in a cool place, remote from lights or fire." *U. S.* "A volatile liquid prepared from ethylic alcohol by interaction with sulphuric acid. It contains not less than 92 per cent. by volume of ethyl oxide, $(C_2H_5)_2O$." *Br.*

Æther Sulphuricus, *Ed., Dub.;* Ether, Hydric Ether, Sulphuric Ether, Naphtha Vitrioli, Hydrate of Ethylen, Oxide of Ethyl; Ether hydrique, ou vinique, ou sulfurique, *Fr.;* Aether, Schwefeläther, *G.*

ÆTHER PURIFICATUS. Br. Purified Ether.

(Æ'THĘR PŪ-RĮ-FĮ-CĀ'TŬS.)

"Ether from which most of the ethylic alcohol has been removed by washing with distilled water, and most of the water by subsequent distillation in the presence of calcium chloride and recently prepared lime." *Br.*

Ether hydrique, *Fr.;* Reiner Aether, *G.*

The U. S. Pharmacopœia of 1880 recognized Æther and Æther Fortior, giving the definitions appended in the foot-note.* The present Æther of the U. S. Pharmacopœia replaces the Æther Fortior of the U. S. P. 1880, the Æther of the U. S. P. 1880 being dropped, as its deficient strength rendered it of little use. The Æther Purificatus of the British Pharmacopœia is somewhat stronger than the Æther of the present U. S. Pharmacopœia, the latter permitting the presence of 4 per cent. of alcohol. The British purified ether, on account of its having the alcohol removed by washing with water, is sometimes termed *Æther Lotum*, or washed ether.

The preparation of ether embraces two stages: its generation,† and its subsequent rectification ‡ to remove impurities. All formulas agree in obtaining it by the action of sulphuric acid on alcohol. In the former United States process, which was adopted, with modifications, from the French Codex, one-third of the alcohol taken is mixed with the acid, and while still hot from the reaction, distilled from a glass retort, by a heat quickly applied, into a refrigerated receiver. When the heat of the mixture has risen to between 130° C. (266° F.) and 137·7° C. (280° F.), the remainder of the alcohol is allowed to enter the retort in a continuous stream, the supply being so regulated that the heat shall be maintained between the degrees mentioned. By a complicated reaction which is explained on page 121, the acid converts the alcohol into ether; and, were it not that the acid becomes more and more dilute as the process proceeds, it would be able to etherize an unlimited quantity of alcohol. Although the acid,

* *Æther*, U. S. 1880. "A liquid composed of about 74 per cent. of Ethyl Oxide $[(C_2H_5)_2O$; **74**—C_4H_5O; 37] and about 26 per cent. of Alcohol containing a little Water. Sp. gr. about 0·750 at 15° C. (59° F.)."

Æther Fortior, U. S. 1880. "A liquid composed of about 94 per cent. of Ethyl Oxide $[(C_2H_5)_2O$; **74**—C_4H_5O; 37] and about 6 per cent. of Alcohol containing a little Water. Sp. gr. not higher than 0·725 at 15° C. (59° F.), or 0·716 at 25° C. (77° F.)."

† The U. S. Pharmacopœia has abandoned all processes for preparing or purifying ether. (See U. S. D., 16th ed., p. 133.) The British process for making ether is appended:

"Take of Rectified Spirit *fifty fluidounces* [Imp. meas.]; Sulphuric Acid *ten fluidounces* [Imp. meas.]; Chloride of Calcium *ten ounces* [avoird.]; Slaked Lime *half an ounce* [avoird.]; Distilled Water *thirteen fluidounces* [Imp. meas.]. Mix the Sulphuric Acid with twelve fluidounces of the Spirit in a glass flask having a wide neck and capable of containing at least two pints [Imp. meas.], and not allowing the mixture to cool, connect the flask by means of a bent glass tube with a Liebig's condenser, and distil at a temperature sufficient to maintain the liquid in brisk ebullition. As soon as the ethereal fluid begins to pass over, supply fresh Spirit through a tube into the flask in a continuous stream, and in such quantity as to equal the volume of the fluid which distils over. For this purpose use a tube furnished with a stop-cock to regulate the supply, connecting one end of the tube with a vessel containing the Spirit raised above the level of the flask, and passing the other end into the acid fluid through a cork fitted into the flask. When the whole of the Spirit has been added, and forty-two fluidounces have distilled over, the process may be stopped. Dissolve the Chloride of Calcium in the Water, add the Lime, and agitate the mixture in a bottle with the impure ether. Leave the mixture at rest for ten minutes, pour off the light supernatant fluid, and distil it until a glass bead of specific gravity 0·735 placed in the receiver begins to float. The ether and spirit retained by the chloride of calcium, and by the residue of each rectification, may be recovered by distillation and used in a subsequent operation." *Br.*

‡ Pure Ether (Æther Purus) of the British Pharmacopœia is made by the following process:

"Take of Ether, Distilled Water, of each, *two pints* [Imperial measure]; Lime, recently burned, *one ounce* [avoirdupois]; Chloride of Calcium, *four ounces* [av.]. Put the Ether with one pint [Imp. meas.] of the Water into a bottle, and shake them together; allow them to remain at rest for a few minutes, and when the two liquids have separated, decant off the supernatant ether. Mix this with the remainder of the Water, and again, after separation, decant as before. Put now the washed ether, together with the Lime and Chloride of Calcium, into a retort to which a receiver is closely attached, let them stand for 24 hours, then distil with the aid of a gentle heat. Sp. gr. not exceeding 0·720." *Br.*

before it becomes too dilute, is capable of determining the decomposition of a certain amount of alcohol, yet it is not expedient to add this amount of alcohol at once; as a considerable portion of it would distil over undecomposed with the ether. The proper way, therefore, is that indicated in the formulas; namely, to commence the process with the use of part of the alcohol, and, when the decomposition is fully established, and a portion of ether has distilled, to add the remainder in a gradual manner, so as to replace that which, every moment of the progress of the distillation, is disappearing by its conversion into ether.

The modifications of the old process were made in conformity with suggestions by Dr. Squibb, contained in a paper published in the *Proc. A. P. A.*, 1858, p. 390. The direction in the 1850 process to reserve a small portion of acid, to be added gradually with the reserved alcohol, upon the supposition that the acid in the retort might be too much weakened to perform its part duly, has been found upon trial to result in no practical advantage. As the proper proportion between the acid and the alcohol is that which requires for ebullition a temperature somewhat above 130° C. (266° F.), or that at which the ether is formed, there is an obvious propriety in supplying the alcohol just so rapidly as may be sufficient to maintain this temperature in the liquid of the retort. If the alcohol be supplied so rapidly as to reduce the temperature below the point mentioned, alcohol will distil over in undue proportion; if too slowly supplied, the temperature will rise so high as to produce other reactions in the materials than that required for etherification, and various other products will result. The rising of the temperature to 141·1° C. (286° F.), after all the alcohol has been added, is, therefore, an indication that the process should be suspended. Nevertheless, the caution to check the process when white vapors appear in the retort is not amiss, as affording an additional security that it shall not be carried too far. At the temperature of 160° C. (320° F.), there will be generated sulphurous acid, heavy oil of wine, olefiant gas, and a large quantity of resino-carbonaceous matter, blackening and rendering thick the residuary liquid; all of them products arising from the decomposition of a portion of sulphuric acid, alcohol, and ether.

The *British* process is that of the Edinburgh Pharmacopœia slightly modified. The principles are the same as those of the U. S. 1870 process; but the directions about temperature are wanting; and the regulation of the supply of alcohol, and the cessation of the operation, are made to depend on the less reliable method of determining the measure of liquid, in the first place in the retort, and in the second place in the receiver.

In both processes, whatever care may be taken in conducting them, and to stop them in due time, the ether obtained is apt to be contaminated with sulphurous acid, heavy oil of wine, alcohol, and water; and hence its purification becomes necessary. For this purpose the crude ether is agitated with purifying agents and submitted to a new distillation at a gentle heat, called the *rectification*. The U. S. Pharmacopœia of 1870 employed an aqueous solution of potassa; the British Pharmacopœia (1885) used a saturated solution of calcium chloride to which had been added lime. The British method of purification as embodied in the formula for Æther Purificatus (see page 118) is preferable to the old United States method, as more thoroughly removing the water. In either case the lime and the potash are equally efficacious in neutralizing any sulphurous acid which may be present in the crude material. The calcium chloride solution, after having been used, yields on distillation a further portion of ether of the official density; and, by concentrating it, filtering while hot, and separating the crystals of calcium sulphite which form on cooling, the chloride may be recovered for future operations.

In the apparatus employed by Dr. Squibb the ether is made in one operation; the vapors of ether and unchanged alcohol are first washed by a solution of caustic potash maintained at a temperature above the boiling point of alcohol, the alcoholic vapor is then condensed in a worm kept at a suitable temperature and runs back into the still, while the ether vapor, retaining about 4 per cent. of alcohol, is condensed in a well-cooled apparatus. 360 lbs. of concentrated sulphuric acid are sufficient to etherify 120 barrels of clean spirit; the acid has then to be changed, chiefly because the impurities of the spirit render the mixture dark and tarry and liable to froth in the still. (*Ephemeris*, ii. p. 590.) Krafft proposes to manufacture ether by heating alcohol in contact with the alkyl esters of sulphonic acid. He states that benzene-sulphonic acid under favorable conditions is capable of converting several thousand times its weight of alcohol into ether. The advantage claimed for this method is greater purity of the resulting ether. (*Chem. Ztg.*, 1893, 1876.) Ekenberg purifies ether by mixing it with 5 or 10 per cent. of liquid paraffin, which has a boiling point of about 300° C., and distilling at a temperature of from 40° to 50° C. The liquid paraffin holds the impurities and permits the pure ether to distil over. (*Chem. Ztg.*, 1894, 1240.)

Properties of Ether. In considering the properties of ether it is necessary to draw a sharp distinction between the official ethers of the two Pharmacopœias. The term Ether (Æther) is used now (1899) for the second grade ether (sp. gr. 0·735) of the British Pharmacopœia as well as for the only ether now recognized by the U. S. Pharmacopœia (sp. gr. 0·725 to 0·728); this latter corresponds with the Purified Ether (Æther Purificatus) of the British Pharmacopœia, which has the sp. gr. 0·720. Ether of the U. S. Pharmacopœia 1890 is described as follows. "A transparent, colorless, mobile liquid, having a characteristic odor, and a burning and sweetish taste. Specific gravity, 0·725 to 0·728 at 15° C. (59° F.); or 0·714 to 0·717 at 25° C. (77° F.). Soluble in about 10 times its volume of water at 15° C. (59° F.), with slight contraction of volume. Miscible, in all proportions, with alcohol, chloroform, benzin, benzol, fixed and volatile oils. Ether boils at about 37° C. (98·6° F.), and it should, therefore, boil when a test-tube, containing some broken glass and half filled with it, is held for some time in the hand. Ether is highly volatile and inflammable. Its vapor, when mixed with air and ignited, explodes violently. The color of light blue litmus paper moistened with water should not be changed when the paper is immersed in Ether for ten minutes. Upon evaporation, Ether should leave *no residue*. If 10 C.c. of it be poured, in portions, upon clean, odorless blotting paper, and allowed to evaporate spontaneously, *no foreign odor* should become perceptible when the last traces of Ether leave the paper. When 20 C.c. of Ether are shaken, in a graduated tube, with 20 C.c. of water, just previously saturated with Ether, the ethereal layer, upon separation, should not measure less than 19·8 C.c. (absence of an *undue amount of alcohol or water*). If 10 C.c. of Ether be shaken occasionally, within one hour, with 1 C.c. of potassium hydrate test-solution, no color should be developed in either liquid (absence of *aldehyde*, etc.)." *U. S.* The British Pharmacopœia gives the following tests for purified ether. "Specific gravity not exceeding 0·722 and not below 0·720. 5 cubic centimetres on spontaneous evaporation should not afford any abnormal odor and should not leave any residue. Its vapor is heavy and highly inflammable. It should dissolve in an equal volume of *carbon bisulphide* (absence of excess of water). Heated, it begins to distil at a temperature not under 94·1° F. (34·5° C.) (absence of methylic ether). No effect should be produced by the addition of *potassium hydroxide* (absence of aldehyde). No alteration in color is produced on moistened *blue litmus paper* after twenty-four hours' contact (absence of acid). On shaking with half its bulk of a dilute solution of *potassium bichromate* acidulated with *sulphuric acid*, and setting aside, the supernatant Ether should have no blue color (absence of hydrogen peroxide). Filter-paper moistened with Purified Ether should remain odorless when the liquid has evaporated."

Commercial ether, which is sometimes used as a solvent, varies in sp. gr. from 0·733 to 0·765. The impurities found in it are excess of alcohol, water, sulphurous and other acids, heavy oil of wine, and various fixed substances.

The ether of U. S. P. 1880 should have the sp. gr. 0·750: if heavier than this, it must contain too much alcohol or water. The statement that water takes up only one-tenth of ether, when equal volumes of ether (sp. gr. 0·750) and water are shaken together in a graduated tube, has been shown by Dr. Squibb to be erroneous. If it take up more than one-fourth, the ether must contain an excess of alcohol or water, or of both. If the alcohol be in excess, it may be removed by agitating the liquid with twice its bulk of water, which unites with the alcohol, forming a heavier stratum, from which the ether may be poured off. The ether, however, takes up about one-tenth of water, which may be removed by agitation with freshly-burned lime, and subsequent distillation. An easy method for detecting and measuring any alcohol present in ether was given by the Edinburgh College; namely, to agitate it, in a minim measure, with half its volume of a concentrated solution of calcium chloride. This will remove the alcohol; and the reduction of the volume of the ether, when it rises to the surface, will indicate the amount. Heavy oil of wine may be discovered by the ether becoming milky upon being mixed with water. If the ether be pure, it wholly evaporates in the air, leaving no solid residue. All non-volatile impurities are thus detected. It should not redden litmus, showing the absence of acids. The point of ebullition is also an indication of the strength of the ether. When evaporating from bibulous paper, it should offer only a slight degree of foreign odor, aromatic and free from pungency, and should leave the paper, when dry, nearly or quite odorless. This test proves the absence of volatile impurities, except a slight and not inadmissible proportion of light oil of wine.

The British ether should have the sp. gr. 0·735. "100 volumes agitated with an equal volume of *water* should not be reduced to less than 90 (absence of excess of ethylic alcohol). It should boil below 105° F. (40·5° C.). Specific gravity 0·735. It evaporates without residue. It should have no action on *solution of litmus*. It should dissolve without coloration when

introduced drop by drop into *sulphuric acid* kept cool during the test (absence of organic impurities)." *Br.* This commercial ether may answer for external application, and may even be given by the mouth, yet for purposes of inhalation it is entirely unfitted without further purification.

The extreme volatility of ether causes it to evaporate speedily in the open air, with the production of considerable cold. Its inflammability is very great, and the products of its combustion are water and carbonic acid. In consequence of this property the greatest care should be used not to bring it in the vicinity of flame, as, for example, a lighted candle. One of the great advantages of using steam as the source of heat is that it obviates, in a great measure, the danger of its accidental inflammation. When too long kept it undergoes decomposition, and is converted in part into acetic acid. It dissolves iodine and bromine freely, and sulphur and phosphorus sparingly. Its power to dissolve corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the organic vegetable alkaloids. It does not dissolve potassa and soda, in which respect it differs from alcohol. Ether unites in all proportions with alcohol. According to Prof. R. Boettger, water may be detected in ether by agitating the suspected liquid with carbon disulphide; if water be present the mixture becomes milky and turbid, otherwise it remains clear. Stefanelli (*Ber. d. Chem. Ges.*, 8, 439) proposes to shake ether with a small fragment of aniline-violet, which does not impart color to ether free from alcohol. One per cent. of alcohol may be thus detected.

The most delicate test for the presence of alcohol in ether is that of Lieben, founded on the formation of iodoform by alcohol but not by ether. (See p. 126.) The mere keeping of ether in presence of moisture is said to generate traces of alcohol sufficient to produce the reaction. (Allen, *Com. Org. Anal.*, 2d ed., i. p. 125.)

On filtering an ethereal liquid with free access of air, a frost-like congelation is observed on the upper part of the filter, its appearance and quantity depending upon the temperature and the hygrometric state of the atmosphere. Tanret has collected some of this *ether hydrate*, and found that after it had been completely freed from ether by strongly blowing upon it, it had the temperature 3·5° C. (25·7° F.), and on fusion yielded 17 to 18 parts of water for 37 of ether; the formula $(C_2H_5)_2O,2H_2O$ requires 18 parts. (*A. J. P.*, 1878.)

Composition and Theory of its Production. The empirical formula of ether is $C_4H_{10}O$, and this is the result both of analysis and of a determination of its vapor density, whereby the molecular weight is established. This formula, however, is better understood when we examine the conditions of its formation. Ether is then found to be the oxide of ethyl (C_2H_5). This is the group which gives character to common alcohol and all its salts, whether with organic or inorganic acids. The group C_2H_5 acts as a monad radical, and common alcohol is its hydrate, $C_2H_5.OH$. Its oxide then would be $(C_2H_5)_2O$, and all the reactions by which ether is produced show it to be this oxide. It is commonly formed from common alcohol (ethyl hydrate) by the action of sulphuric acid, according to the following reactions:

$$C_2H_5,OH + SO_2,OH,OH = SO_2,OH,OC_2H_5 + H,OH;$$

that is, alcohol reacting with sulphuric acid yields ethyl-sulphuric acid (sulphovinic acid) and water. In the presence of an excess of alcohol and at the proper temperature the ethyl-sulphuric acid then reacts with another molecule of alcohol, as follows:

$$C_2H_5,OH + SO_2,OH,OC_2H_5 = C_2H_5,OC_2H_5 + SO_2,OH,OH,$$

whereby ethyl oxide (ether) is formed, and sulphuric acid is regenerated. These reactions take place best at a temperature of about 140° C. (284° F.), and if the mixture in the flask is kept at this temperature a steady stream of alcohol can be converted into ether, whence the process has been called "the continuous etherification process."

Medical Properties and Uses. The chief use of ether in medicine is as an anæsthetic; although when taken into the stomach it is absorbed and exerts its narcotic powers. Locally applied it acts at first as a stimulant and afterwards as a narcotic. If it be on an exposed surface its evaporation occurs so rapidly as to mask by refrigeration the direct action of ether. It was at one time employed for freezing parts about to be operated upon, but has been superseded by the more volatile and cheaper petroleum products. It is frequently employed in *nausea* dependent upon gastric depression, and also in *flatulent* or even *biliary colic;* it is sometimes effective in *gastrodynia*, in *neuralgia of the gums*, *earache*, etc. When applied locally its evaporation should be prevented if possible. When ether is taken into the general system it produces an increase of the force and frequency of the pulse, which appears to be due to a stimulant action both upon the heart and vaso-motor system. The augmentation of

the force of the circulation is remarkably well maintained even during profound etherization, and after death from ether poisoning the heart is usually, if not always, found to be beating. When the drug causes a fatal result, it is almost always by paralyzing the centres of respiration. In sufficient amount ether acts powerfully as a narcotic, suspending consciousness and also lessening reflex activity. In some subjects there is a stage of etherization in which sensibility is destroyed, although consciousness is preserved. The influence of ether upon the nervous system is a direct one, and the usual order of the involvement of the nerve-centres as shown by Flourens is: first the cerebrum, next the sensory centres of the cord, next the motor centres of the cord, next the sensory centres of the medulla, and finally the motor centres (including that of respiration) of the medulla.

For external use, the unrectified ether is sufficiently pure. The internal dose of ether is from fifty drops to a teaspoonful, to be repeated frequently when the full effect of the remedy is desired. It may be given in capsules, or simply floating upon the surface of ice-cold water, or incorporated in an aqueous mixture, to be made by first rubbing it up with spermaceti, employed in the proportion of two grains for each fluidrachm of the ether.

A *syrup of ether* is directed by the French Codex. MM. J. Regnault and Adrian, after a thorough investigation of the solubility of ether in solutions of sugar, offer the following formula. Take of sugar 440 parts, distilled water 490 parts, alcohol at 90° 50 parts, pure ether 20 parts. Put into a bottle, shake, and preserve. The whole of this might be given at a dose, if the parts taken are represented by grains.

Capsules of ether, also called *pearls of ether*, are inodorous, will keep for a year at least without loss, and furnish the means of introducing ether into the stomach without irritating the mouth and throat. In a few seconds after they arrive in the stomach, they burst and diffuse their effects with singular rapidity. Analogous effects are produced when they are introduced into the rectum or vagina. Ether may be gelatinized by the process of M. Grimault. This consists in briskly shaking, in a stoppered bottle, four measures of ether, free from alcohol and acid, with one measure of white of egg. *Gelatinized ether* is an opaline trembling jelly, which may be spread with the greatest facility. It may be used as a local anæsthetic, applied to the seat of pain, spread on linen, and covered with a piece of cloth or of sheet caoutchouc. Gelatinized ether will not keep, but must be prepared at the time it is wanted.

Etherization. Ether may be exhibited by inhalation. Many years ago, its use in this way was proposed by Drs. Beddoes, Pearson, and Thornton, of England, in certain diseases of the lungs. As early as 1805, the late Dr. Warren, of Boston, employed ethereal inhalation to relieve the distress attending the last stage of pulmonary inflammation. About the year 1812, in Philadelphia, at the time when the nitrous oxide was the subject of popular lectures, the vapor of ether was frequently breathed from a bladder for experiment or diversion; and its effects in producing transient intoxication, analogous to that caused by the nitrous oxide, were observed. It was not, however, until October, 1846, that attention was particularly drawn to ethereal inhalation as a remedy for pain. In that month, Dr. Warren, of Boston, was applied to by Dr. W. T. G. Morton, dentist, of that city, to ascertain by trial whether an agent which he had successfully employed to render painless the extracting of teeth would be equally successful in preventing the pain of surgical operations. This agent was the vapor of ether. Dr. Warren acceded to this request, and shortly afterwards, at the Massachusetts General Hospital, performed a severe operation, without pain to the patient, under the influence of ether, administered by Dr. Morton. A few days subsequently, Dr. C. T. Jackson, of Boston, in conversation with Dr. Warren, claimed to have first made known to Dr. Morton the use of ethereal vapor for the prevention of pain in dental operations.

From this beginning, the employment of ether by inhalation for the prevention and removal of pain has spread throughout the civilized world. The effect produced, called *etherization*, is usefully resorted to in all severe operations, not merely for the prevention of pain, but also of the shock which the system would otherwise suffer as a consequence of the pain, and also as a means of producing muscular relaxation in *dislocation*, *strangulated hernias*, etc. It has been employed for the detection of *feigned diseases*, by suspending the operation of the will; in *neuralgia*, *biliary* or *renal colic*, *dysmenorrhœa*, etc., as a palliative; in *tetanus*, and in the *spasms* produced by an overdose of strychnine, as an antispasmodic; and in *asthma* and *chronic bronchitis*, as an antispasmodic expectorant. In midwifery it is extensively employed. In vivisections, humanity calls for the use of it as an anæsthetic.

When ether is inhaled, at first a short faucial irritation is generally produced, but this soon disappears; and, after the lapse of from two to five minutes, and the expenditure of about

two fluidounces of ether, the quantity being very variable in different cases, the patient becomes insensible, and appears as if in a deep, almost apoplectic sleep. The usual signs of the full effect of the ether are the closure of the eyelids, muscular relaxation, and inability to answer questions. During the whole process of etherization, the fingers should be kept on the pulse; and if it become feeble, or very slow, or very rapid, the sponge should be removed until the circulation improves. At first there is redness, afterwards paleness, of the face and neck, succeeded by cold perspirations. The danger in etherization is rarely through failure of the circulation, but by arrest of the respiration, and the state of the latter function should be closely watched; should it become very slow, or shallow, or irregular, the anæsthetic should be withdrawn, and, if necessary, appropriate measures of relief adopted. This is the mode of proceeding in surgical operations; in midwifery cases, partial etherization is often sufficient. One of the drawbacks to the use of ether is that vomiting is very apt to occur and be severe during the recovery from the narcosis. To lessen the gastric disturbance as much as possible, no food should be allowed for some hours before etherization, and a moderate dose of brandy or whiskey should be administered at the beginning of the latter process. In a few instances etherization has produced alarming remote effects. Dr. F. D. Lente has reported three cases of this kind. (*New York Journ. of Med.*, Nov. 1856.) It cannot be gainsaid that ether used for surgical purposes has caused death in a considerable number of cases. It appears to be distinctly proved by an enormous mass of statistics that the ratio of deaths from chloroform is about four times greater than from ether; so that under ordinary circumstances the surgeon should always select ether rather than chloroform, especially as most of the so-called "disadvantages" of ether can be overcome by a little care. When in any case of disease of the heart anæsthesia is necessary, ether is a much safer anæsthetic than is chloroform. On the other hand, in *phthisis*, *chronic bronchitis*, in *emphysema*, *pneumonia*, and even *pleurisy*, and especially in *laryngitis* or *obstructive diseases* of the *larynx*, chloroform is distinctly preferable to ether. The question which of the anæsthetics is the safer when there is disease of the kidneys cannot be positively answered at this time, but what statistics there are indicate that ether is less dangerous than is chloroform, although the contrary statement has been made by various surgeons.

ALCOHOL. U. S. (Br.) Alcohol.

(ĂL'CŌ-HŎL.)

"A liquid composed of about 91 per cent., by weight, or 94 per cent., by volume, of Ethyl Alcohol [$C_2H_5OH = 45{\cdot}9$], and about 9 per cent., by weight, of Water. Alcohol should be kept in well-closed vessels, in a cool place, remote from lights or fire." *U. S.* "A liquid containing 90 parts by volume of ethyl hydroxide, C_2H_5OH, and 10 parts by volume of water; obtained by the distillation of fermented saccharine liquids." *Br.*

Spiritus Rectificatus, *Br.*, Rectified Spirit; Spiritus, *P. G.;* Spiritus Vini Rectificatissimus, Alcohol Vini; Spirit of Wine; Alcool, Esprit de Vin, *Fr.;* Rectificirter Weingeist, *G.;* Alcoole, Acquavite rectificata, *It.;* Alcohol, Espíritu rectificado de Vino, *Sp.*

ALCOHOL ABSOLUTUM. U. S., Br. Absolute Alcohol.

C_2H_5OH; 45·9. (ĂL'CŌ-HŎL ĂB-SŌ-LŪ'TŬM.)

"Ethyl Alcohol, containing not more than 1 per cent., by weight, of Water. Absolute Alcohol should be kept in well-stoppered bottles or tin cans, in a cool place, remote from lights or fire." *U. S.* "Ethyl hydroxide, C_2H_5OH, with not more than 1 per cent., by weight, of water; obtained by the removal of water from less strong ethylic alcohol, and subsequent distillation." *Br.*

ALCOHOL DEODORATUM. U. S. Deodorized Alcohol.

(ĂL'CŌ-HŎL DĒ-Ō-DŌ-RĀ'TŬM.)

"A liquid composed of about 92·5 per cent., by weight, or 95·1 per cent., by volume, of Ethyl Alcohol [$C_2H_5OH = 45{\cdot}9$], and about 7·5 per cent., by weight, of Water. Deodorized Alcohol should be kept in well-closed vessels, in a cool place, remote from lights or fire." *U. S.*

ALCOHOL DILUTUM. U. S. Diluted Alcohol.

(ĂL'CŌ-HŎL DĪ-LŪ'TŬM.)

"A liquid composed of about 41 per cent., by weight, or about 48·6 per cent., by volume, of absolute Ethyl Alcohol [$C_2H_5OH = 45{\cdot}9$], and about 59 per cent., by weight, of Water. It

should be kept in well-closed vessels, in a cool place, remote from lights or fire." *U. S.* "The four official liquids obtained by diluting Alcohol (90 per cent.) with Distilled Water contain respectively 70, 60, 45, and 20 per cent. of ethyl hydroxide by volume." *Br.*

Spiritus Tenuior, *Br.*, 1885, Proof Spirit; Spiritus Dilutus, *P. G.;* Spiritus Vini Rectificatus; Alcool dilué, *Fr.;* Verdünnter Spiritus, *G.*

From the titles and definitions above given, which include all the forms of alcohol recognized by the U. S. and Br. Pharmacopœias, it will be perceived that there are four official Alcohols, those being considered the same which approach nearly in specific gravity and are employed for similar purposes.

The very extended use of alcohol in pharmacy renders it desirable not only to group the official kinds together here, but to consider each in detail in the subsequent pages. In the U. S. P. (1890) two new kinds of alcohol were made official, "Alcohol Absolutum" and "Alcohol Deodoratum." The former, which had been made official in the British Pharmacopœia (1885) under the title "Alcohol Ethylicum," is in the Br. P. (1898) termed "Alcohol Absolutum," so that the two Pharmacopœias are now in accord.

Alcohol, in the chemical sense, is a peculiar liquid, generated for the most part in vegetable juices and infusions by a *fermentation*, called the *vinous* or *alcoholic*. The liquids which have undergone it are called vinous liquors, and are of various kinds. Thus, the fermented juice of the grape is called wine; of the apple, cider; and the fermented infusion of malt, beer.

With regard to the nature of the liquids susceptible of the vinous fermentation, however various they may be in other respects, one general character prevails; that, namely, of containing sugar in some form or other. It is found, further, that after they have undergone the vinous fermentation the sugar they contain has either wholly or in part disappeared; and it was long believed that the only new products are alcohol which remains in the liquid, and carbonic acid which escapes during the process, and that these, when taken together, are equal in weight to the sugar lost. It was hence inferred that sugar is the subject-matter of the changes that occur during the vinous fermentation, and that it is resolved into alcohol and carbonic acid. More recently, however, it has been shown by M. Pasteur that, along with alcohol and carbonic acid, glycerin and succinic acid are generated in small amount, and that the process is not so simple as at first supposed.

Sugar will not undergo the vinous fermentation by itself, but requires to be dissolved in water, subjected to the influence of a ferment, and kept at a certain temperature. Accordingly, sugar, water, the presence of a ferment, and the maintenance of an adequate temperature may be deemed the prerequisites of the vinous fermentation. The water acts by giving fluidity, and the ferment and temperature by commencing and maintaining the chemical changes. The precise manner in which the ferment operates has not been positively determined; but the fermentative change seems to be intimately connected with the multiplication of a microscopic vegetable, *torula cerevisiæ*. Pasteur has shown that the yeast plant lives and grows at the expense of the sugar, which is converted partly into the tissue of the plant, partly into alcohol and other products. The proper temperature for conducting the vinous fermentation ranges from 15·5° C. to 32·2° C. (60° to 90° F.).

Certain vegetable infusions, as those of potatoes and rice, readily undergo vinous fermentation, on account of the ease with which their starch is changed into sugar under the influence of certain ferments. Taking the formula of starch as $(C_6H_{10}O_5)_3$ for illustration, it is first changed under the influence of dilute acids or ferments according to the two reactions

$$(C_6H_{10}O_5)_3 + H_2O = \underset{\text{Dextrin.}}{(C_6H_{10}O_5)_2} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}$$

$$(C_6H_{10}O_5)_3 + 2H_2O = \underset{\text{Maltose.}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}.$$

The two compounds, *dextrin* and *maltose*, then go over gradually into dextrose, according to the reactions

$$(C_6H_{10}O_5)_2 + 2H_2O = 2C_6H_{12}O_6$$
$$C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6.$$

Neither dextrin nor maltose is directly fermentable. M. Arnoult has succeeded in obtaining alcohol by fermenting sugar (glucose), formed by the action of sulphuric acid on poplar wood sawdust, which yielded from 70 to 80 per cent. of this kind of sugar.

Alcohol, being the product of the vinous fermentation, necessarily exists in all vinous liquors, and may be obtained from them by distillation. Formerly it was supposed that these liquors did not contain alcohol, but were merely capable of furnishing it, in consequence of a new arrangement of their ultimate constituents, the result of the heat applied. Brande, how-

ever, disproved this idea, by showing that alcohol may be obtained from all vinous liquors without the application of heat, and therefore must pre-exist in them. His method of separating it consists in precipitating the acid and coloring matter from each vinous liquor by lead subacetate, and removing the water by potassium carbonate. According to Gay-Lussac, litharge, in fine powder, is the best agent for precipitating the coloring matter.

In vinous liquors, the alcohol is largely diluted with water, and associated with coloring matter, volatile oil, extractive, ethereal substances, and various acids and salts. In purifying it, we take advantage of its volatility, which enables us to separate it by distillation, combined with some of the principles of the vinous liquor employed, and more or less water. The distilled product of vinous liquors forms the different *ardent spirits of commerce.* When obtained from wine, it is called brandy; from fermented molasses, rum; from cider, malted barley, or rye, whiskey; from malted barley and rye-meal with hops, and rectified from juniper berries, Holland gin; from malted barley, rye, or potatoes, and rectified from turpentine, common gin; and from fermented rice, arrack.* These spirits are of different strengths, that is, contain different proportions of alcohol, and have various peculiarities by which they are distinguished by the taste. Their strength is accurately judged of by the specific gravity, which is always less in proportion as their concentration is greater.† When they have the sp. gr. 0·920 (0·91984, *Drinkwater*), they are designated in commerce by the term *proof spirit.* If lighter than this, they are said to be above proof; if heavier, below proof; and the percentage of water, or of spirit of 0·825, necessary to be added to any sample of spirit to bring it to the standard of proof spirit, indicates the number of degrees the given sample is above or below proof. Thus, if 100 volumes of a spirit require 10 volumes of water to reduce it to proof spirit, it is said to be "10 over proof." On the other hand, if 100 volumes of a spirit require 10 volumes of spirit of 0·825 to raise it to proof, it is said to be "10 under proof."

Proof spirit is still very far from being pure; being a dilute alcohol, containing about half its weight of water, together with a peculiar oil and other foreign matters. It may be further purified and strengthened by redistillation, or *rectification* as it is called. Whiskey is the spirit usually employed for this purpose; and from every hundred gallons, between fifty-seven and fifty-eight may be obtained, of the average strength of rectified spirit (sp. gr. 0·835), corresponding very nearly with the *Spiritus Rectificatus* of the British. When this is once more cautiously distilled, it will be further purified from water, and the sp. gr. attained will be about 0·820, which is the lightest spirit that can be obtained by ordinary distillation, and is practically the pure spirit of the British system of excise. It still, however, contains 11 per cent. of water. In the mean while, the spirit, by these repeated distillations, becomes more and more freed from the contaminating oil, called *grain oil* or *fusel oil.* (See *Alcohol Amylicum.*) The synthesis of alcohol from ethylene through the intervention of ethyl-sulphuric acid has long been known as a scientific possibility. Recently, with the production of acetylene industrially from calcium carbide, this synthesis has been taken up as a commercial possibility. Acetylene, made as stated from calcium carbide and water, is generated in the same flask in which nascent hydrogen is being formed, the result being the formation of ethylene gas. This is brought in contact with concentrated sulphuric acid at 80° C., when the two unite to form ethyl-sulphuric acid, which is then condensed and redistilled, when it breaks up into alcohol and sulphuric acid, which later can be used over again. The reactions for this synthesis are:

$$C_2H_2 \text{ (acetylene)} + H_2 \text{ (hydrogen)} = C_2H_4 \text{ (ethylene)},$$
$$C_2H_4 \text{ (ethylene)} + H_2SO_4 = (C_2H_5)HSO_4 \text{ (ethyl-sulphuric acid)},$$
$$C_2H_5HSO_4 + HOH = C_2H_5.OH \text{ (alcohol)} + H_2SO_4.$$

We shall first consider the general properties of alcohol, and afterwards the different official forms.

* It is stated that in Eastern commerce, under the name of *toddy, arrack, saki,* and *tsin,* is sold a liquid which has only once been distilled; whilst *sam-shu* is a thrice distilled rice spirit, and contains from 33 to 52 per cent. of absolute alcohol. (*Journ. Am. Chem. Soc.,* 1885.)

† H. Grouven (*Vortr. über Agriculturchemie,* i. 425; *N. R.,* May, 1879) gives the following average percentages of alcohol, as contained in the ordinary liquors:

	Vol. per cent.	Weight per cent.		Vol. per cent.	Weight per cent.
Scotch Whiskey	50·3	42·8	Rum	49·7	42·2
Irish "	49·9	42·3	Gin	47·8	40·3
American " (old)	60·0	52·2	German "Schnapps"	45·0	37·9
English "	49·4	41·9	Russian "Dobry Wutky"	62·0	54·2
French Cognac (Brandy)	55·0	47·3			

The percentage of alcohol in American whiskey is usually lower than that given above.

Properties. Alcohol, using this term in a generic sense, is a colorless, transparent, volatile liquid, of a penetrating, agreeable odor, and burning taste. It should be free from foreign odor, which, when present, is owing to fusel oil. When free from water, it is called *anhydrous* or *absolute alcohol.* It is inflammable, and burns without smoke or residue, forming water and carbonic acid. Its flame is bluish when strong, but yellowish when weak. It combines in all proportions with water and ether; and, when diluted with distilled water, preserves its transparency. Its density varies with the proportion of water it contains. (See table on p. 127.) Its value depends upon the quantity of absolute alcohol contained in it; and, as this is greater in proportion as the sp. gr. is less, it is found convenient to take the density of a sample in estimating its strength. This is done by instruments called hydrometers, which, when allowed to float in the spirit, sink deeper into it in proportion as it is lighter. Each hydrometer strength has a corresponding specific gravity; and, by referring to tables constructed for the purpose, the percentage of absolute alcohol is at once shown. Dr. W. H. Pile & Son, makers of hydrometers in Philadelphia, graduate instruments showing specific gravity and Baumé's degrees upon the same scale in parallel columns, with a thermometer taking the place of the bulb; these are exceedingly convenient.

Alcohol is used enormously in the arts as a solvent and for other purposes, and governments have long sought for suitable regulations which would permit the proper use of alcohol in manufacturing and control its use as a beverage. The substitution of *methylated spirit* (alcohol with 10 per cent. of methyl alcohol) has not proved effective. (See *Methylic Alcohol*, PART II.) The French excise directs that alcohol should be denatured or deprived of its natural properties by the addition of 500 C.c. of benzin and 1 Gm. of malachite green to each hectolitre; it has been found, however, that the color can be destroyed by calcium hypochlorite.

Alcohol is capable of dissolving a great number of substances; as, for example, sulphur and phosphorus in small quantity, iodine and ammonia freely, and the hydrates of potassium, sodium, and lithium, but not the carbonates of these metals. Among organic substances, it is a solvent of the organic vegetable alkalies, urea, tannic, citric, and tartaric acids, sugar, mannite, camphor, resins, balsams, volatile oils, and soap. It dissolves the fixed oils sparingly, except castor oil, which is abundantly soluble in it. It reacts chemically with some acids, forming the ethyl ethers, but with others acts only as a solvent. All deliquescent salts are soluble in alcohol, except potassium carbonate; while the efflorescent salts, and those either insoluble or sparingly soluble in water, are mostly insoluble in it. It dissolves ammonium chloride, and most of the chlorides readily soluble in water; also some nitrates, but none of the metallic sulphates.

A method of detecting alcohol in small proportions has been proposed by M. Carstanjin. The liquid supposed to contain it, having been mixed with platinum black in a small flask, is heated to 51·1° C. (124° F.), well shaken, and filtered. To the filtrate a few drops of solution of potassa are added, and the liquor evaporated to dryness on a water-bath. The residue is then heated with a little arsenous acid; when, if alcohol be present, a garlicky odor will be perceived, owing to the production of cacodyl. According to M. Nickles, however, propylic alcohol will produce the same result. (*A. J. P.*, 1865, p. 334.) A very delicate test for small quantities of alcohol is that of Lieben as modified by Hager. (*Zeitsch. Anal. Chem.*, ix. 492.) It depends on the fact that alcohol under the influence of iodine and an alkali yields iodoform, CHI_3, the properties of which are very characteristic. To 10 C.c. of the clear suspected liquid five or six drops of a 10-per-cent. solution of caustic potash or soda are added, and the liquid is warmed to about 50° C. (122° F.). A solution of potassium iodide fully saturated with free iodine is next added drop by drop, with agitation, until the liquid becomes permanently yellowish brown, when it is carefully decolorized by a further cautious addition of the caustic alkali solution. If alcohol be present, iodoform is gradually deposited at the bottom of the tube in yellow crystals, which, after standing, may be examined with a lens. Spirit diluted with 2000 parts of water, when treated as above and allowed to stand twelve hours, gives a distinct dust-like deposit of iodoform. Unfortunately, the above delicate reaction is not peculiar to alcohol, being produced by acetone, aldehyde, propylic and butyric alcohols, various ethers, etc. On the other hand, it is not given by pure methyl or amyl alcohol, chloroform, chloral, glycerin, or ether, nor by acetic, formic, or oxalic acid. (Allen, *Commercial Org. Anal.*, 2d ed., i. p. 59; see, also, *A. J. P.*, Feb. 1877, Feb. 1879, Nov. 1879; *N. R.*, Aug. 1876.) Prof. Barfoed, of Copenhagen, recommends for an approximate simple test, to moisten small slips of filtering paper thoroughly with the alcohol, and set fire to them. If, when the alcohol has burned out, the paper slip catches fire readily, the latter must be stronger than 80

per cent.; if the paper barely catches fire, the strength may be presumed to be between 75 and 80 per cent.; if it does not catch fire at all, the alcohol cannot be stronger than 73 to 75 per cent. (*A. J. P.*, Jan. 1875.)

The following table, compiled from that of Dr. A. B. Lyons, will be found useful, because it gives the specific gravities and proportions of *official* alcohol and water required to make 100 measures at the temperature of 15·5° C. (60° F.). Condensation is taken into account in these figures. Corresponding specific gravities and percentages of mixtures of *absolute* alcohol and water may be found by referring to the alcoholmetrical tables in the Appendix.

1. Alcohol Absolutum. *Absolute Alcohol, Anhydrous Alcohol, Ethylic Alcohol.* No process is given in the U. S. Pharmacopœia for the preparation of absolute alcohol; the definition given, however, is "Ethyl Alcohol, containing not more than 1 per cent., by weight, of water;" the following is the process of the Br. Pharmacopœia (1885): "Rectified Spirit, 1 pint [Imp. meas.]; Carbonate of Potassium, anhydrous, 2 ounces [av.]; Chloride of Calcium, fused, a sufficiency. Add the carbonate of potassium to the spirit in a stoppered bottle, and macerate for twenty-four hours with frequent agitation. Put the chloride of calcium into a covered crucible, and subject it to a red heat for half an hour; then pour the fused salt on to a clean stone slab, cover it quickly with an inverted porcelain dish, and when it has congealed, break it up into small fragments and enclose in a dry stoppered bottle. Put one pound [av.] of this fused chloride of calcium into a flask, pour over it the spirit decanted from the carbonate of potassium, and, closing the mouth of the flask with a cork, shake them together and allow them to stand for twenty-four hours with repeated agitation. Then attaching a dry condenser closely connected with a receiver from which free access of air is excluded, and applying the flame of a lamp to the flask, distil about two fluidounces [Imp. meas.], which should be returned to the flask, after which the distillation is to be continued until fifteen fluidounces [Imp. meas.] have been recovered." *Br.* By the term absolute alcohol is meant pure alcohol, entirely free from water. In this state it cannot be obtained by ordinary distillation alone; the purest alcohol thus procured still containing 11 per cent. of water. To separate this it is customary to have recourse to substances having a very strong affinity for water, sufficient not only to abstract it from the alcohol, but to retain it at a temperature at which alcohol will distil over. Soubeiran recommends the following method for obtaining it, and the British process is largely based

upon this plan. 1st. Rectify alcohol marking 86° of the centesimal alcoholmeter of Gay-Lussac (rectified spirit), by distilling it from potassium carbonate. This operation should raise its strength to 94° or 95°. 2d. Raise this alcohol to 97° by distilling it with fused calcium chloride, or by digesting it with quicklime (from which it must be afterwards poured off), in the proportion of a pint of the alcohol to 1½ ounces of the chloride, or 2¼ ounces of the lime. 3d. Distil the product of this operation slowly with quicklime, in the proportion of 3¾ ounces to the pint. The product will be absolute alcohol. The operation may be shortened to two steps by distilling the alcohol of 94° or 95° with an excess of quicklime (7½ ounces to the pint). In all cases, before decanting or distilling, the alcohol must be digested for two or three days with the lime, at a temperature between 95° and 100° F. Lime will not answer as a substance to be distilled from, unless it be in sufficient excess; for otherwise, towards the end of the distillation, the calcium hydrate formed will yield up its water to the alcohol, and weaken the distilled product. Prof. J. Lawrence Smith (*Amer. Chemist*, Oct. 1874) procures an alcohol of 98 to 100 per cent. by macerating 3 pints of alcohol, 94 per cent., in a four-pint bottle with about six troyounces of well-burned lime; well corked and agitated at intervals for ten days, the strengthened alcohol, at the end of this time, is drawn off by a siphon, and may be freed, if desired, of the small trace of lime by redistillation.

Properties. Absolute alcohol is a colorless, volatile liquid, of an agreeable odor and burning taste. It boils at 78·4° C. (173·1° F.), and is congealed at —130·5° C. Its sp. gr. is 0·7978 at 68°, according to Regnault; 0·79381 at 60°, according to Drinkwater; 0·794 (equivalent to 99·95 per cent. of ethyl hydroxide by volume and by weight) to 0·7969 (equivalent to 99·4 per cent. of ethyl hydroxide by volume or 99 per cent. by weight), by the British Pharmacopœia; while Dr. Squibb has shown that pure alcohol is obtainable of as low a density as 0·7935, and possibly lower. (*Ephemeris*, ii. p. 522.) The sp. gr. of its vapor is 1·59. Absolute alcohol is officially described as "a transparent, colorless, mobile, and volatile liquid, of a characteristic, rather agreeable, odor, and a burning taste. Very hygroscopic. Specific gravity, not higher than 0·797 at 15·6° C. (60° F.); or 0·789 at 25° C. (77° F.). In other respects, Absolute Alcohol has the properties, and should respond to the reactions and tests, of Deodorized Alcohol (see *Alcohol Deodoratum*)." *U. S.* "Mixed with 1 to 2 per cent. of anhydrous *copper sulphate* in a well-closed bottle, and the mixture set aside for two or three hours and occasionally well shaken, the salt does not become of a decidedly blue color (absence of excess of water). Absolute Alcohol should be free from the impurities mentioned under 'Alcohol (90 per cent.),' and in other general characters should resemble it." *Br.* The tests usually given to prove the absence of water by dropping into the absolute alcohol anhydrous baryta or anhydrous copper sulphate are not reliable, as Dr. Squibb has demonstrated that when half of one per cent. of water was added to absolute alcohol no change in either the baryta or the anhydrous copper sulphate took place. Görgeu's test of forming a clear solution when mixed with an equal bulk of pure benzol is more delicate, but a test for determining the presence of at least one per cent. of water is badly needed. Absolute alcohol should be free from fusel oil. Absolute alcohol burns with a pale flame without residue, the products being carbonic acid and water. Its vapor, passed through a porcelain tube filled with pumice-stone and heated to redness, yields carbon, gaseous hydrocarbons, aldehyde, naphthalene, benzene, phenol, and various other substances. (*Berthelot.*) It unites in all proportions with ether and water. Its union with water is attended by condensation and a rise of temperature. When 52·6 volumes of alcohol are mixed with 47·4 of water, corresponding with one molecule of the former to three of the latter, the decrease of volume is at the maximum, amounting to 3·4 per cent. Berthelot has announced the formation of alcohol synthetically, by the union of olefiant gas with water. In this discovery he was anticipated by the late Mr. Hennel, who published it in 1828.

Composition. Absolute alcohol consists of two atoms of carbon, six of hydrogen, and one of oxygen. Its empirical formula is, therefore, C_2H_6O. It is, however, recognized, as the hydrate of the radical ethyl (C_2H_5), so that its rational formula would be $C_2H_5.OH$.

During the vinous fermentation sugar disappears, and the sole products were supposed to be alcohol and carbonic acid, which, taken together, were believed to equal in weight the lost sugar. Now, the comparative composition of the substances concerned supports the opinion that these are the sole derivatives of a portion of the sugar lost. Preparatory to the fermentation, the cane sugar is changed into *grape sugar*, or into a mixture of equal molecules of *dextrose* and *levulose*, called *invert* sugar, according to the reaction given on page 123. These two sugars, dried at 100° C. (212° F.), consist of $C_6H_{12}O_6$. Supposing one mol. of this fermentable sugar to be the subject of the change, it will be found to have a composition

which admits of its being broken up into two mols. of alcohol and two of carbonic acid; for $C_6H_{12}O_6 = 2(C_2H_6O) + 2(CO_2)$. But it does not follow that all the sugar has been converted into alcohol and carbonic acid; and Pasteur, as before stated, has shown that a portion lost has not been thus converted, but has been partly appropriated to the growth of the yeast plant of the ferment, and partly changed into glycerin and succinic acid.

2. ALCOHOL. *U. S. Alcohol*, sp. gr. 0·820. This is the so-called "95 per cent. alcohol" of commerce (or 94 per cent. by volume); it was an official preparation of the Dublin College, which gave a formula for its preparation, and stated its sp. gr. at 0·818. The Stronger Alcohol introduced into the U. S. P. (1860), though of the sp. gr. 0·817, and therefore a little stronger than the old Dublin preparation, may for all practical purposes be considered as identical with it. The British Pharmacopœia (1898), under the title "Spiritus Rectificatus," recognizes alcohol of 90 per cent. This is slightly stronger (1·35 per cent. by volume) than the alcohol of the same name in the Br. Pharm. (1885). To prepare it on a small scale, potassium carbonate, previously ignited in a heated mortar, may be mixed with ordinary alcohol in a bottle, and shaken occasionally for about four hours; the mixture being, in the mean time, maintained at the temperature of about 100° F. Upon resting, the liquid divides into two strata, the lower consisting of an aqueous solution of potassium carbonate, the upper of the stronger alcohol, which is to be separated, and distilled so as to obtain the measure of about nine-tenths of the original alcohol employed.

It is described as "a transparent, colorless, mobile, and volatile liquid, of a characteristic, rather agreeable odor, and a burning taste. Specific gravity, about 0·820 at 15·6° C. (60° F.); or 0·812 at 25° C. (77° F.). Miscible with water in all proportions, and without any trace of cloudiness; also miscible with ether or chloroform. It is readily volatilized even at low temperatures, and boils at 78° C. (172·4° F.). It is inflammable, and burns with a blue flame. It should not affect the color of blue or red litmus paper previously moistened with water. If 50 C.c. of Alcohol be evaporated in a clean glass vessel, no *color* or *weighable residue* should remain. On allowing Alcohol, mixed with one-third of its volume of water, to evaporate spontaneously from clean, odorless blotting-paper saturated with it, no odor of *fusel oil*, nor *other foreign odor*, should become perceptible. If 10 C.c. of Alcohol be mixed in a test-tube with 5 C.c. of potassium hydrate test-solution, the liquid should not at once become dark-colored (absence of *aldehyde*, *methyl alcohol*, or *oak tannin*). If 20 C.c. of Alcohol be shaken in a clean, glass-stoppered vial with 1 C.c. of silver nitrate test-solution, the mixture should not become more than faintly opalescent, or acquire more than a faint brownish tint, when standing during six hours in diffused daylight (limit of *organic impurities*, *amylic alcohol*, etc.)." *U. S.* "Specific gravity 0·8340. It contains 85·65 per cent. by weight of ethyl hydroxide, C_2H_5OH, and 14·35 per cent. by weight of water. It burns with a blue smokeless flame. It leaves no residue when evaporated (absence of fixed matter). It remains clear when mixed with *water* (absence of oily or resinous substances). A little exposed on clean white filter-paper leaves no unpleasant smell after the alcohol has evaporated (absence of fusel oil and allied impurities). 100 cubic centimetres, with 2 cubic centimetres of the *volumetric solution of silver nitrate*, exposed for 24 hours to bright light and then decanted from the black powder which has formed, undergo no further change when again exposed to light with more of the *volumetric solution* (absence of more than traces of amylic alcohol and of other organic impurities). When mixed with half its volume of *solution of potassium hydroxide*, the liquid should not immediately darken in color (absence of more than traces of aldehyde). The addition of *solution of ammonia* should not cause an immediate darkening in color (absence of tannic acid, excess of aldehyde, and other organic impurities)." *Br.*

On a large scale, we are informed that alcohol of this strength is now prepared in the United States, very abundantly, by simple distillation by means of a modified distillatory apparatus. The modification consists in substituting for a single refrigerated receiver a series of receivers, kept at such temperatures that, in the first of them, the watery vapor shall condense with comparatively little of the alcoholic, which, as it passes through the successive recipients, is more and more deprived of water, until, when condensed in the last, it yields a spirit at least as strong as the official Alcohol of the sp. gr. 0·820. At the same time that the spirit is thus strengthened, it becomes, on the same principle, more and more freed from fusel oil, until at length almost wholly deprived of it.

The British preparation contains 14·35, the U. S. only 9 per cent. of water. Official alcohol, though of standard strength, may still be impregnated with a volatile principle, called *fusel oil*. This is usually separated by digesting the alcohol with charcoal. It, as well as other impuri-

ties, may also be removed by passing the impure spirit through a filtering bed, composed of sand, wood-charcoal, boiled wheat, and broken oyster-shells, arranged in layers. If 5 C.c. of alcohol be mixed with 6 times its volume of water and then agitated with about 20 drops of chloroform, the latter will, if separated and allowed to evaporate spontaneously, leave the fusel oil, which will be perceptible by its odor; and by treating with a little sulphuric acid and potassium acetate, its peculiar ether may be recognized by its odor. (*Ber. Chem. Ges.*, viii.; *A. J. P.*, 1875, p. 304.) If a little of the solution of silver nitrate be added to alcohol, and the mixture exposed to a bright light, a black powder will be precipitated, if fusel oil be present. Official alcohol will not withstand this test, as the best contains a little of the foreign oil. According to Mr. E. N. Kent, of New York, silver nitrate will not detect fusel oil, but affords its indications by reacting with other organic substances. For detecting fusel oil, Mr. Kent finds pure sulphuric acid the best test. To apply it he half fills a test-tube with the spirit to be tested, and then fills it up very slowly with pure concentrated sulphuric acid. If the spirit be pure, it will remain colorless, otherwise it will become colored, the tint being deeper in proportion to the amount of the impurity. This test admits the presence of a small proportion of fusel oil.

Alcohol Deodoratum. *Deodorized Alcohol.* "A liquid composed of about 92·5 per cent., by weight, or 95·1 per cent., by volume, of Ethyl Alcohol [$C_2H_5OH = 45·9$], and about 7·5 per cent., by weight, of water." *U. S.* This is a new official liquid of the U. S. P. 1890. Deodorized alcohol is, as its name implies, alcohol deprived of foreign odor; there are certain uses in pharmacy for which any other alcohol would be unsuited, such as the solution of volatile oils and essences having delicate odors, the manufacture of compound spirits, etc.

The properties of deodorized alcohol are those of purified alcohol, its specific gravity, 0·816 at 15·6° C. (60° F.), being slightly less than that of alcohol. It is officially tested as follows. "If 25 C.c. of Deodorized Alcohol be mixed with an equal volume of water and 5 C.c. of glycerin, and the mixture allowed to evaporate spontaneously from a piece of clean, odorless blotting-paper, *no foreign odor* should become perceptible when the last traces of the Alcohol leave the paper (absence of *fusel oil constituents*). If 25 C.c. be allowed to evaporate spontaneously in a porcelain capsule carefully protected from dust, until only a moisture is left, no red or brown color should be produced upon the addition of a few drops of colorless, concentrated sulphuric acid (absence of *amylic alcohol*, or *non-volatile*, *carbonizable*, *organic impurities*, etc.). In other respects, Deodorized Alcohol has the properties, and should respond to the reactions and tests, of *Alcohol*." *U. S.*

The best alcohol is that manufactured under Atwood's patent process, in which manganic acid or potassium or sodium permanganate is used to destroy the fusel oil and other foreign substances. This alcohol withstands the tests of silver nitrate and sulphuric acid remarkably well. Pure fused sodium acetate has been proposed as a substance particularly adapted to retain fusel oil, and has been used by adding it to the alcohol to be rectified in the proportion of about 10 pounds to the barrel of forty-five gallons, and redistilling. The purification of alcohol is best accomplished, according to Schmitt, by taking crude alcohol containing 30 per cent. by volume, adding potassium carbonate (not enough to cause two layers to form), and agitating with pure benzin; this solvent removes completely the fusel oil from the alcohol. After separating the light layer, potassium carbonate is added to the alcohol in sufficient quantity to form two layers, the lower one consisting of a saturated solution of potassium carbonate, the upper one of 94-per-cent. alcohol containing a small quantity of potassium carbonate. The alcohol layer is siphoned off and mixed with just sufficient strong sulphuric acid to precipitate the potassium salt as sulphate, which is insoluble in alcohol of 94 per cent., and which can then be removed. Alcohol purified in this manner, without distillation, it is stated, cannot be distinguished from that purified by the usual method. (See *Pharm. Centralb.*, 1889, p. 722.) F. G. Earl recommends the following method, which has the advantage of requiring no especial apparatus. "Rub four drachms of powdered unslaked lime with two drachms of powdered alum intimately; add one gallon (95 per cent.) alcohol and shake well, then add one fluidrachm of spirit of nitrous ether, set aside for seven days, and filter through animal charcoal." (*Chem. and Drug.*, 1895, 35.) *Perfumers' alcohol* can now be had, which is very much cleaner than *cologne spirit*, as the purest alcohol attainable was formerly called. It is termed perfumers' alcohol because it was found necessary to prepare a very high grade of alcohol for those who need a solvent for fine odors, on the score of economy and to insure greater excellence of product.

3. Alcohol Dilutum. *U. S.* "A liquid composed of about 41 per cent., by weight, or

about 48·6 per cent., by volume, of absolute Ethyl Alcohol, and about 59 per cent., by weight, of Water." Specific gravity about 0·938 at 15° C. (59° F.) and about 0·930 at 25° C. (77° F.). The strength of diluted alcohol has been somewhat altered by the U. S. Pharmacopœia of 1890.

*Diluted alcohol is now officially made by mixing equal measures of alcohol and water together.** "Alcohol, *five hundred cubic centimeters* [or 16 fluidounces, 7 fluidrachms, 15 minims]; Distilled Water, *five hundred cubic centimeters* [or 16 fluidounces, 7 fluidrachms, 15 minims]. Mix them. If the two liquids be measured at the temperature of 15·6° C. (60° F.), the mixture, when cooled to the same temperature, will measure about 971 C.c. [or 32 fluidounces, 6 fluidrachms, 40 minims]. *Diluted Alcohol* may also be prepared in the following manner: Alcohol, *four hundred and ten grammes* [or 14 ounces av., 202 grains]; Distilled Water, *five hundred grammes* [or 17 ounces av., 279 grains]. Mix them." *U. S.*

The British Pharmacopœia (1898) no longer uses the titles "Spiritus Tenuior" or "Proof Spirit" for diluted alcohol, but admits four official liquids under the name of diluted alcohol, as follows:

1. **Alcohol (70 per cent.).**—With *one hundred fluid ounces* of Alcohol (90 per cent.) mix *thirty-one* (more accurately 31·05) *fluid ounces* of Distilled Water. Or, with *one thousand cubic centimetres* of Alcohol (90 per cent.) mix *three hundred and ten and a half* (310·5) *cubic centimetres* of Distilled Water. Specific gravity 0·8900.

2. **Alcohol (60 per cent.).**—With *one hundred fluid ounces* of Alcohol (90 per cent.) mix *fifty-three and two-thirds* (more accurately 53·65) *fluid ounces* of Distilled Water. Or, with *one thousand cubic centimetres* of Alcohol (90 per cent.) mix *five hundred and thirty-six and a half* (536·5) *cubic centimetres* of Distilled Water. Specific gravity 0·9135.

3. **Alcohol (45 per cent.).**—With *one hundred fluid ounces* of Alcohol (90 per cent.) mix *one hundred and five and one-third* (more accurately 105·34) *fluid ounces* of Distilled Water. Or, with *one thousand cubic centimetres* of Alcohol (90 per cent.) mix *one thousand and fifty-three and a half* (more accurately 1053·4) *cubic centimetres* of Distilled Water. Specific gravity 0·9436.

4. **Alcohol (20 per cent.).**—With *one hundred fluid ounces* of Alcohol (90 per cent.) mix *three hundred and fifty-five and three-quarters* (more accurately 355·8) *fluid ounces* of Distilled Water. Or, with *one thousand cubic centimetres* of Alcohol (90 per cent.) mix *three thousand five hundred and fifty-eight* (3558·0) *cubic centimetres* of Distilled Water. Specific gravity 0·9760.

This is a convenient pharmaceutical method of providing suitable menstrua for making tinctures, fluid extracts, and other galenical preparations.

The U. S. preparation consists of equal measures of official alcohol and water. "Diluted Alcohol has a specific gravity of about 0·938 at 15° C. (59° F.), about 0·937 at 15·6° C. (60° F.), and about 0·930 at 25° C. (77° F.). It should respond to the reactions and tests given under *alcohol*."

Medical Properties and Uses. Probably all the soft tissues of the body are capable of being impressed by alcohol, if it be in sufficient amount and concentration. Locally applied it is irritant even to the skin, and much more so to the more delicate organs: hence the various abdominal inflammations which are so frequent in habitual drunkards. When it is taken internally in proper quantity, it causes a feeling of exhilaration, with distinct increase in the force and frequency of the pulse. When larger amounts are ingested, the well-known phenomena of drunkenness follow. A single dose of it, if large enough, may produce death, preceded by loss of consciousness, profound muscular relaxation, and diminished respiration. The temperature of the body may be elevated slightly by small doses of the drug, the rise

* *Official Rules for making an Alcohol of any required lower Percentage, from an Alcohol of any given higher Percentage.* "I. *By Volume.*—Designate the volume-percentage of the stronger alcohol by *V*, and that of the weaker alcohol by *v*.

"*Rule.*—Mix *v* volumes of the stronger alcohol with pure water to make *V* volumes of product. Allow the mixture to stand until full contraction has taken place, and until it has cooled, then make up any deficiency in the *V* volumes by adding more water.

"*Example.*—An alcohol of 30 per cent. by volume is to be made from an alcohol of 94 per cent. by volume.—Take 30 volumes of the 94 per cent. alcohol, and add enough pure water to produce 94 volumes.

"II. *By Weight.*—Designate the weight-percentage of the stronger alcohol by *W*, and that of the weaker by *w*.

"*Rule.*—Mix *w* parts by weight of the stronger alcohol with pure water to make *W* parts by weight of product.

"*Example.*—An alcohol of 50 per cent. by weight is to be made from an alcohol of 91 per cent. by weight.—Take 50 parts by weight of the 91 per cent. alcohol, and add enough pure water to produce 91 parts by weight." *U. S.*

being due to the excitement of the circulation and not to any direct action. After toxic amounts the temperature is usually lowered, and the fall may be very marked. The action of the drug upon the bodily temperature of those who use it habitually is very slight.

Alcohol in small doses acts as a stimulant to the ganglionic cells of the cerebrum, and perhaps also to the motor tract of the spinal cord. In large amount it certainly is a depressant to the cerebral and spinal ganglionic cells, as well as the nerve-trunks. The action of small doses upon the respiratory centres is not thoroughly established, but large doses depress the respiratory centres, and finally may cause death by centric paralytic asphyxia. Upon the heart the small dose of alcohol acts as a direct stimulant, the large dose as a depressant or paralyzant. The influence of minute doses upon the vaso-motor system is not thoroughly worked out, but there appears to be a widening of the blood-paths at a time when the heart is still stimulated, so that there is a marked quickening of the blood-movement. The toxic dose of alcohol paralyzes the blood-vessels, probably both centrally and peripherally. The peripheral temperature is often increased by small amounts of alcohol, and there may be even a slight increase in the central temperature, probably caused by quickening of the circulation; the large dose of alcohol depresses the animal temperature, probably by causing vaso-motor paralysis, and thereby increasing heat-dissipation.

In regard to the effect of alcohol upon the nutrition there is much contradictory evidence, but the present probabilities are that the drug has no specific influence upon the production of heat or of carbonic acid, or upon nitrogenous elimination, and that therefore it has little or no direct effect upon the nutrition, unless it be in poisonous doses, when it certainly disturbs all nutritive processes. After absorption into the blood, alcohol is in part eliminated through the lungs, the skin, and the kidneys unchanged, but is largely burnt up in the system, probably yielding force for the working needs of the organism. Whether as a food it is in health of as much or more value than other hydrocarbons is not at present positively known.

In acute diseases associated with *debility*, alcohol is often an invaluable remedy. Of all medicines it is the one most frequently employed as a stimulant. Taken along with food in small quantity, it favors digestion by its local effect upon the stomach, and possibly also by stimulating the nerve and arterial centres. It does not directly elevate temperature, and hence is not contra-indicated by fever; in *typhoid* and other *low fevers* it is of great value. In all conditions of depression the system tolerates much more of it than in health: hence in *snake-bite*, *typhoid* and *typhus fever*, *diphtheria*, etc., enormous quantities are often exhibited with great benefit. So long as it is not perceptible in the breath, and does not cause nervous or circulatory excitement, alcohol in these cases is probably not in excess. In chronic diseases great care is necessary in the exhibition of the remedy, for fear of begetting intemperate habits. This is especially the case in *neuralgia* and other painful affections in which the narcotic influence of alcohol may be very soothing; under these circumstances there is a constant tendency to an increase of the frequency and size of the dose. Taken habitually in excess, alcohol produces the most deplorable results, and is a very common cause of fatal maladies. In acute poisoning, the stomach should be at once emptied, the respiration be maintained by the use of atropine and other methods (see *Opium Poisoning*), and the bodily heat sustained by external warmth. In some cases it may be well to employ ammonia or digitalis to act upon the nearly paralyzed heart. Locally, alcohol is sometimes used for the purpose of hardening the skin and as an antiseptic dressing for wounds, the wound being washed out with it until all bleeding has ceased, the edges then united, and the whole surrounded by an alcoholic dressing. As an internal remedy alcohol is very rarely employed in the pure state, but only in the form of spirits, wines, or fermented liquors, which are described elsewhere.

The purer forms of alcohol, whether strong or diluted, are employed almost exclusively in pharmacy; as in the preparation of medicines, such as ether, into the composition of which they enter; for the preservation of organic substances; in the extraction of the active principles of vegetables, as in the tinctures; for dissolving bodies soluble in alcohol much more readily than in water, or insoluble in the latter fluid; and for other pharmaceutical purposes. Diluted alcohol is employed as an addition to some infusions and decoctions, and to some of the distilled waters and preparations of vinegar, in order to preserve them from decomposition; as a menstruum for extracting the virtues of plants, preparatory to the formation of extracts and syrups; and in preparing many of the spirits, and a few of the medicated wines. But it is in forming the tinctures that diluted alcohol is chiefly used. Some of these are made with official alcohol (rectified spirit), but the majority with mixtures of alcohol and water of differ-

ent percentages. As diluted alcohol contains more than half its weight of water, it is well fitted for acting on organic substances the virtues of which are partly soluble in water and partly in alcohol. The apothecary, however, should never substitute the commercial proof spirit for diluted alcohol, on account of the impurities in the former, even though it may be of the same strength; but when it is recollected how variable the so-called proof spirits are in strength, the objection to their use in pharmacy becomes still stronger.

ALLIUM. U. S. Garlic.

(ĂL'LĮ-ŭM.)

"The bulb of Allium sativum, Linné (nat. ord. Liliaceæ)." *U. S.*

Bulbus Allii; Ail, *Fr.;* Knoblauch, *G.;* Aglio, *It.;* Ajo, *Sp.*

Gen. Ch. Corolla six-parted, spreading. *Spathe* many-flowered. *Umbel* crowded. *Capsule* superior. *Willd.*

This is a very extensive genus, including more than sixty species, most of which are European. Of the nine or ten indigenous in this country, none are official. Dr. Griffith states that the bulb of *A. canadense* has been substituted for the cultivated garlic, and found equally efficient. (*Med. Bot.*, p. 653.) Of the European species several have been used from a very early period, both as food and as medicine. *A. sativum*, or garlic, is the only one now official; and to this we shall here confine our observation, simply stating that there are few genera of which the several species resemble one another more closely in sensible and medical properties than the present. For an account of *A. cepa*, or onion, and *A. porrum*, or leek, see PART II.

Allium sativum. Willd. *Sp. Plant.* ii. 68; Woodv. *Med. Bot.* p. 749, t. 256. This is a perennial plant, and, like all its congeners, bulbous. The bulbs are numerous, and enclosed in a common membranous covering, from the base of which the fibres that constitute the proper root descend. The stem is simple, and rises about two feet. The leaves are long, flat, and grass-like, and sheathe the lower half of the stem. At the termination of the stem is a cluster of flowers and bulbs mingled together, and enclosed in a pointed spathe, which opens on one side and withers. The flowers are small and white, and make their appearance in July. This species of garlic grows wild in Sicily, Italy, and the south of France.

The part employed, as well for culinary purposes as in medicine, is the bulb, which is described in the U. S. Pharmacopœia as follows. "Bulb subglobular, compound, consisting of about eight compressed, wedge-shaped bulblets, which are arranged in a circle around the base of the stem, and covered by several dry, membranous scales. Odor pungent and disagreeable; taste warm and acrid. Garlic should be used without having been dried." *U. S.* The bulbs are dug up with a portion of the stem attached, and, having been dried in the sun, are tied together in bunches, and thus brought to market. They are said to lose, by drying, nine parts of their weight out of fifteen, with little diminution of their sensible properties. This species of Allium is commonly called *English garlic*, to distinguish it from those which grow wild in our fields and meadows. Garlic bulbs are apt to germinate and thus to undergo serious injury. Mr. A. P. Sharp preserves them by placing them in a bottle, pouring on them a little alcohol, about two fluidounces to a quart, and securely closing the bottle by a stopper of glass or cork. All tendency to germinate is thus destroyed, and the bulbs will retain their peculiar smell and taste unchanged for years. (*Proc. A. P. A.*, 1864.)

Properties. Garlic, as found in the shops, is somewhat spherical, flattened at the bottom, and drawn towards a point at the summit, where a portion of the stem several inches in length projects. It is covered with a white, dry, membranous envelope, consisting of several delicate laminæ, within which the small bulbs are arranged around the stem, having each a distinct coat. These small bulbs, commonly called *cloves* of garlic, are usually five or six in number, of an oblong shape, somewhat curved, and in their interior are whitish, moist, and fleshy.* They have a disagreeable pungent odor, so peculiar as to have received the name of *alliaceous.* Their taste is bitter and acrid. The peculiar smell and taste, though strongest in the bulb, are found to a greater or less extent in all parts of the plant. They depend on an *essential oil*, which is very volatile, and may be obtained by distillation, passing over with the first portions of water. As first obtained, the oil is of a dark brownish-yellow color, heavier than water, and decomposed at its boiling temperature. It may be purified by repeated distillation in a

* A variety of garlic, sometimes seen in the market, having larger and fewer cloves or small bulbs than the official, has been shown by Prof. Robert P. Thomas to be the product of a hybrid, probably between *A. sativum* and *A. porrum.* (*Proc. A. P. A.*, 1860.)

salt-water bath, and is then lighter than water, of a pale yellow color, and not decomposed by boiling. According to Wertheim, it consists of a peculiar organic radical, called *allyl*, (C_3H_5), combined with sulphur, and is therefore allyl sulphide, $(C_3H_5)_2S$. From one hundred-weight of garlic Wertheim obtained from three to four ounces of the impure oil, and about two-thirds as much of the rectified. (*Chem. Gaz.*, iii. 177.) Semmler obtained from garlic bulbs 0·09 per cent. of the volatile oil, sp. gr. (at 14·5° C.) 1·0525; it was yellow, having an intense odor and optically inactive. By fractional distillation he obtained four products, $C_6H_{12}S_2$, $C_6H_{10}S_2$, $C_6H_{10}S_3$, and $C_6H_{10}S_4$, which decomposed during distillation. The oil, according to Semmler, is free from allyl sulphide, the latter having the sp. gr. 0·8991. (*Arch. d. Pharm.*, 1892, p. 434.) The impure oil has an exceedingly pungent odor, and a strong acrid taste, and, when applied to the skin, produces much irritation and sometimes even blisters. The pure oil combines with silver nitrate, forming a precipitate soluble in heated alcohol and afterwards separating in crystals. Besides this oil, fresh garlic, according to Cadet de Gassicourt, contains, in 1406 parts, 520 of mucilage, 37 of albumen, 48 of fibrous matter, and 801 of water. Bouillon-Lagrange mentions among its constituents sulphur, a saccharine matter, and a small quantity of fecula. The fresh bulbs yield upon pressure nearly a fourth part of juice, which is highly viscid, and so tenacious as to require dilution with water before it can be easily filtered. When dried, it serves as a lute for porcelain. It has the medical properties of the bulbs. Water, alcohol, and vinegar extract the virtues of garlic. Protracted boiling renders it inert. According to F. W. Semmler (*Arch. d. Pharm.*, 1887, p. 927), *Allium ursinum* contains a volatile oil which consists mainly of *vinyl-sulphide*, C_4H_6S or $(C_2H_3)_2S$.

Medical Properties and Uses. The use of garlic as a medicine and as a condiment ascends to the highest antiquity. When taken internally, and even when applied externally, the oil is absorbed, and imparts its odor to the breath, urine, perspiration, etc. The oil of garlic has some influence upon the human system as a general mild stimulant. Its chief value in medicine is for its local action upon the stomach and as a stimulant expectorant. The garlic itself is sometimes employed as a rubefacient, which by yielding its volatile oil in absorption stimulates the nervous system, especially in the case of young children. The oil may often be given with great advantage in *chronic bronchitis* and in the advanced stages of *obstinate acute bronchitis*. It is especially valuable in the treatment of children when there is a distinct nervous element. In *catarrhal pneumonia* of young children the bruised garlic cloves are often applied as a poultice to the lungs; and similar applications were formerly used to the feet for the *nervous restlessness* or even the *convulsions* of young children. Garlic clove may be swallowed either whole or cut into pieces of a convenient size, but the official syrup has replaced most other methods of administration. The dose in substance is from half a drachm to two drachms (1·95–7·8 Gm.) of the fresh bulb. That of the juice is half a fluidrachm (1·9 C.c.).

ALOE BARBADENSIS. U. S., Br. Barbadoes Aloes. [Curaçao Aloes.]

(ĂL'Ǫ-Ę BĂR-BĄ-DĔN'SIS.)

"The inspissated juice of the leaves of Aloe vera (Linné), Webb (nat. ord. Liliaceæ)." *U. S.*

"The juice that flows from the transversely cut leaves of Aloe vera, Linn., Aloe chinensis, Bak., and probably other species, evaporated to dryness. Imported from the West Indian Islands, and known in commerce as Barbados and Curaçao aloes." *Br.*

Aloès hépatique des Barbades, *Fr.;* Barbadoes Aloe, *G.*

ALOE SOCOTRINA. U. S., Br. Socotrine Aloes.

(ĂL'Ǫ-Ę SŎC-Ǫ-TRĪ'NA.)

"The inspissated juice of the leaves of Aloe Perryi, Baker (nat. ord. Liliaceæ)." *U. S.*

"The juice that flows from the transversely cut leaves of Aloe Perryi, Baker, and probably other species of Aloe, evaporated to dryness. Imported principally by way of Bombay, and known in commerce as Socotrine and Zanzibar aloes." *Br.*

Aloès socotrin, ou sucotrin, *Fr.;* Socotora oder Socotrinische Aloe, *G.;* Musebber, *Ar.*

Most of the species belonging to the genus Aloe are said to yield a bitter juice which has all the properties of the official aloes. It is impossible, from the various and sometimes conflicting accounts of writers, to determine exactly from which of the species the drug is in all instances actually derived. Mr. J. Medley Wood states, as the result of personal research in

Natal, that the Natal aloes is yielded chiefly by the aloe described in the *Gardener's Chronicle*, vol. 5, p. 113, as *A. ferox.* (*P. J. Tr.*, Dec. 1890.) Doubts are, however, thrown upon the conclusions of Mr. Wood by Mr. E. M. Holmes, who thinks that the plant seen was probably *A. platylepis.* (See *P. J. Tr.*, April, 1891.) In Lindley's Flora Medica, *A. purpurascens*, *A. arborescens*, *A. commelyni*, and *A. multiformis*, of the Cape of Good Hope, are enumerated as yielding aloes; *A. leptocaulon* and *A. sahnudra*, found in Madagascar (*P. J. Tr.*, July, 1881), and other species, are, without doubt, occasionally resorted to. We shall confine ourselves to a description of the three species which probably yield most of the aloes of commerce.

Gen. Ch. Corolla erect, mouth spreading, bottom nectariferous. *Filaments* inserted into the receptacle. *Willd.*

Aloe spicata. Willd. *Sp. Plant.* ii. 185. This species of Aloe was first described by Thunberg. The stem is round, three or four feet high, about four inches in diameter, and leafy at the summit. The leaves are spreading, subverticillate, about two feet long, broad at the base, gradually narrowing to the point, channelled upon their upper surface, and with remote teeth upon their edges. The flowers are bell-shaped, and spread horizontally in very close spikes. Beneath each flower is a broad, ovate, acute bract, white, with three green streaks, and nearly as long as the corolla. Of the six petals, the three inner are ovate, obtuse, white, with three green lines, and broader than the outer, which otherwise resemble them. The stamens are much longer than the corolla. The *spiked aloe* is a native of Southern Africa, growing near the Cape of Good Hope, and, like all the other species, preferring a sandy soil. In some districts of the colony it is found in great abundance, particularly at Zwellendam, near Mossel Bay, where it almost covers the surface of the country. Much of the Cape aloes is said to be derived from this species.

A. socotrina. Lamarck, *Encycl.* i. 85; De Cand. *Plantes Grasses, fig.* 85; Curtis's *Bot. Mag. pl.* 472; Carson's *Illust. of Med. Bot.* ii. 48, *pl.* 92.—*A. vera.* Miller, *Dict., ed.* 8, *No.* 55. The stem of this species is erect, eighteen inches or more in height, woody, and leafless below, where it is very rough from the remains of former leaves. At top it is embraced by green, sword-shaped, ascending leaves, somewhat concave on their upper surface, convex beneath, curved inward at the point, with numerous small white serratures at their edges. The flowers, which are in a cylindrical, simple raceme, are scarlet near the base, pale in the centre, and greenish at the summit, and have unequal stamens, of which three are longer than the corolla.

This plant was supposed to be a native of Socotra and the source of the Socotrine aloes, but was shown by Mr. Bolus to be indigenous to the Cape of Good Hope.

A. vulgaris. Lamarck, *Encycl.* i. 86; Carson's *Illust. of Med. Bot.* ii. 46, *pl.* 90.—*A. vera.* Linn.—*A. barbadensis*, Miller. This species has a very short, woody stem, and lanceolate embracing leaves, which are first spreading, then ascending, of a glaucous green color, somewhat mottled with darker spots, flat on the upper surface, convex beneath, and armed with hard reddish spines, distant from each other, and perpendicular to the margin. The flower-stem is axillary, of a glaucous reddish color, and branched, with a cylindrical-ovate spike of yellow flowers, which are at first erect, then spreading, and finally pendulous, and do not exceed the stamens in length. *A. vulgaris* is a native of southeastern Europe, the north of Africa, and Madagascar. It is cultivated in Italy, Sicily, Malta, and especially in the West Indies, where it contributes largely to furnish the Barbadoes aloes.

A. perryi. J. G. Baker, *Journ. Linn. Soc.*, xxviii. The true Socotrine aloes plant was first described from specimens sent to Kew Gardens by Mr. Wykeham Perry, and was subsequently found by Prof. Balfour, of Edinburgh, growing abundantly upon the island of Socotra, especially in the limestone tracts, from the sea-level to an altitude of 3000 feet; along with it, but much less abundant, was a dwarf species with spotted leaves. *A. perryi* resembles in its general habit the Barbadoes aloe, but differs in its shorter leaves, and especially in its flowers, which are arranged in looser racemes on longer pedicels and have the tube much longer than the segments.

The proper aloetic juice was formerly thought to exist in longitudinal vessels beneath the epidermis of the leaves, and readily flows out when these are cut transversely; but, according to M. Edmond Robiquet, who has made elaborate researches in relation to this drug, these vessels are air-ducts, and the juice flows in the intercellular passages between them. The liquid obtained by expression from the parenchyma is mucilaginous, and possessed of little medicinal virtue. The quality of the drug depends much upon the mode of preparing it. The finest kind is that obtained by exudation, and subsequent inspissation in the sun. Most of the better sorts, however, are prepared by artificially heating the juice which has spontaneously

exuded from the cut leaves. The chief disadvantage of this process is the conversion of a portion of the soluble active principle into an insoluble and comparatively inert substance, through the influence of an elevated temperature. The plan of bruising and expressing the leaves, and boiling down the resulting liquor, yields a much inferior product, as a large portion of it must be derived from the mucilaginous juice of the parenchyma. The worst plan of all is to boil the leaves themselves in water, and evaporate the decoction. The quality of the drug is also affected by the careless or fraudulent mixture of foreign matters with the juice, and the unskilful management of the inspissation.

Commercial History and Varieties. Three chief varieties of aloes are known in commerce: Barbadoes or Curaçao, Socotrine, and Cape.

1. Barbadoes Aloes. Curaçao Aloes. The aloe plants are largely cultivated in the poorer soils of Jamaica and Barbadoes, especially of the latter island. The species from which most of the drug is procured is *A. vulgaris;* but *A. socotrina*, *A. purpurascens*, and *A. arborescens* are also said to be cultivated. The process employed appears to be somewhat different in different places, or at least as described by different authors. A fine kind was formerly prepared by the spontaneous inspissation of the juice placed in bladders or shallow vessels and exposed to the sun. The common Barbadoes aloes, however, is now made either by boiling the juice to a proper consistence, or by first forming a decoction of the leaves, chopped and suspended in water in nets or baskets, and then evaporating the decoction. In either case, when the liquor has attained such a consistence that it will harden on cooling, it is poured into calabashes and allowed to concrete. A gentleman from Barbadoes, who had seen the aloes prepared, informed Mr. Squire that the leaves are cut transversely, and so placed that the juice flows from the incised surfaces into a trough which inclines to the boiler. (*Med. T. and Gaz.*, Jan. 1868, p. 75.) It is imported into England in gourds weighing from 60 to 70 pounds, or even more, or sometimes in boxes. A variety known as "*Capey Barbadoes*," having a smooth glassy fracture, occurs in the London markets. In consequence of the great demand for it in veterinary practice, it commands a high price in Great Britain. *Curaçao aloes*, resembling Barbadoes aloes but having a different odor, comes into European commerce through Holland from the Dutch West Indies. It is apparently produced by the three species *A. vulgaris*, *A. spicata*, and *A. socotrina*, all of which have been introduced into the islands (see *P. J. Tr.*, Jan., Sept., 1890), although Prof. E. R. Holmes believes it to be at least in part the product of *A. chinensis*. This aloe was formerly largely used in making the dye known as Bismarck brown, but at present is chiefly employed in medicine.

The color of Barbadoes aloes is not uniform. Sometimes it is dark brown or almost black, sometimes of a reddish-brown or liver color, often orange-brown, and again of some intermediate shade. "Fracture either dull and waxy, in which case small splinters are opaque; or smooth and glassy, in which case the splinters are transparent; the opaque variety examined under the microscope exhibits numerous minute crystals embedded in a transparent mass." *Br.* It is also distinguishable by its odor, which is disagreeable and even nauseous. The powder is of a dull olive-yellow. According to Mr. Giles, it yields 80 per cent. of aqueous extract, and is even more active than is the Socotrine. (*P. J. Tr.*, Dec. 1860, p. 301.) According to M. Marais, Barbadoes aloes, from whatever part of the West Indies derived, and however differing in color, when dissolved in distilled water in the proportion of 1 part to 100,000 parts, has in a high degree the property of giving rise to a fine rose color on the addition of gold chloride or tincture of iodine; while all other varieties, whether African or Indian, with the exception of the hepatic, produce with these reagents either a feeble color, slow in developing, or no change of color whatever. (*Journ. de Pharm.*, 4e sér., v. 336.) "Mixed with nitric acid, it acquires a red color. Barbadoes Aloes is not colored, or acquires only a light bluish-green tint, on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from *Natal aloes*)." *U. S.* "Barbados Aloes is almost entirely soluble in *alcohol* (90 per cent.) diluted with half its volume of *water*. Not more than 30 per cent. should be insoluble in cold *water*." *Br.* Kremel gives a method to distinguish Curaçao aloes from other kinds by adding to it a little cupric sulphate solution, then some saturated solution of common salt, which makes the color an intense carmine. The reaction is due to *cupro-alvin*. (*Chem and Drug.*, 1895, 759.)

2. Socotrine Aloes. This aloes, which has been very long known and highly esteemed under its present name, is nominally produced in the island of Socotra, which lies in the Strait of Babelmandeb, about forty leagues to the east of Cape Guardafui; but we are told by Ainslie that the greater part of what is sold under that name is prepared in the kingdom of Melinda,

upon the eastern coast of Africa; and Wellsted states that the aloes of the neighboring parts of Arabia is the same as that of Socotra. The commerce in this variety of aloes is carried on chiefly by the maritime Arabs, who convey it either to India, or up the Red Sea by the same channel through which it reached Europe before the discovery of the southern passage into the Indian Ocean. Mr. Vaughan states that nearly the whole product of the island is carried to Maculla, on the southern coast of Arabia, and thence transshipped to Bombay. (*P. J. Tr.*, xii. 268.) The whole produce was formerly monopolized by the Arabian Sultan of Kisseen; but at present the business of collecting the drug is entirely free to the inhabitants. The leaves are plucked at any period of the year, and are placed in skins, into which the juice is allowed to exude. In what way the inspissation is effected we are not informed by Wellsted; but, according to Hermann, it is by exposure to the heat of the sun. The aloes is exported in skins, or in kegs or tin-lined boxes. Its quality differs much according to the care taken in its preparation.

Socotrine aloes is in pieces of a yellowish or reddish-brown or even a dark ruby-red color, wholly different from that of the former variety. Sometimes the color is very light, especially in the fresh and not fully hardened parcels; sometimes it is a deep brownish red like that of garnets. It is rendered much darker by exposure to the air; and the interior of the masses is consequently much lighter-colored than the exterior. Its surface is somewhat glossy, and its fracture smooth or ragged, but not conchoidal. The color of its powder is a bright golden yellow. It has a peculiar, almost fragrant, saffron-like odor, which is especially developed by breathing upon it, and a taste which, though bitter and disagreeable, is accompanied by an aromatic flavor. Though hard and pulverulent in cold weather, it is somewhat tenacious in summer, and softens by the heat of the hand. The variety known as *Zanzibar aloes* is usually imported in liver-brown masses. It has a dull and waxy, but nearly smooth and even, fracture, a characteristic odor, and a nauseous, bitter taste. "Almost entirely soluble in alcohol and in 4 parts of boiling water. The aqueous solution becomes turbid on cooling and yields a deposit. The powder, on being thoroughly dried on a water-bath and then heated to 100° C., should not cake. Mixed with nitric acid, it acquires a reddish-brown color. Socotrine Aloes is not colored blue on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from *Natal aloes*)." *U. S.* Both Zanzibar and true Socotrine Aloes "are opaque even in small splinters, exhibit when examined under the microscope numerous minute crystals embedded in a transparent mass, and impart to *nitric acid* a reddish or yellowish-brown color." *Br.*

Under the name of Socotrine aloes are occasionally to be met with in the market small parcels beautifully semi-transparent, shining, and of a yellowish, reddish, or brownish-red color. These, however, are very rare, and do not deserve to be considered as a distinct variety. They are probably portions of the juice carefully inspissated in the sun, and may accompany the packages brought from any of the commercial sources of aloes. When in mass, as imported from the East, Socotrine aloes is usually soft and plastic, and of a very light yellowish-brown color in the interior. At present it reaches the United States in casks, tubs, or boxes, and not rarely in a semi-liquid state, forming, when dried, hard dark-brown, or nearly black masses which break with a dull and waxy, uneven fracture. Very liquid specimens are sometimes of the consistence of molasses, of an orange or yellowish color, and of a strong fragrant odor. It separates, upon standing, into a transparent liquid, and an opaque, lighter-colored, granular portion which subsides. Pereira found the latter portion to consist of innumerable minute prismatic crystals, which he believed to be identical with or closely analogous to aloïn. When the juice is heated, the deposit dissolves, and the whole being evaporated yields a solid, transparent product having the properties of fine Socotrine aloes. (*P. J. Tr.*, xi. 439.)

Much of the aloes sold as Socotrine consists simply of superior specimens of other varieties falsely labelled to enhance their value.

Much confusion and uncertainty have prevailed in relation to the term *Hepatic Aloes*. The name was originally applied to a product from the East Indies of a reddish-brown or liver color, and has been extended to similar aloes from the West Indies. The hepatic aloes of the present London markets is simply a dark, opaque, liver-colored Socotrine aloes.

The Barbadoes aloes reaches the United States in gourds, the Curaçao aloes in old boxes and various forms of packages, whilst the Socotrine aloes comes chiefly in monkey-skins.

3. Cape Aloes (*Shining Aloes*) was dropped from the U. S. Pharmacopœia at the revision of 1880. It is imported from the Cape of Good Hope, either directly or through the medium of English commerce. It is collected by the Hottentots and Dutch boers indiscriminately

from *A. spicata* and other species, which grow wild in great abundance. Mr. Backhouse (1838), Dr. L. Pappe, of Cape Town, and Mr. P. MacOwan (1871), all state that the best aloes is derived from *Aloe ferox* (*Lam.*), and, according to Dr. L. Pappe, a weaker product is obtained from *A. africana* and *A. plicatilis* of Miller. (*Flor. Capens.* 28.) The process is very simple. As stated by Hallbeck, a Moravian missionary who resided at the Cape, a hole is made in the ground, in which a sheep-skin is spread with the smooth side upward. The leaves are then cut off near the stem, and arranged around the hole, so that the juice which runs out may be received into the skin. The juice flows most freely in hot weather. (*United Breth. Mission. Intelligencer, N. Y.*, vi. 436.) When a sufficient quantity of the liquor has been collected, it is inspissated in iron caldrons, and, when sufficiently concentrated, is poured into boxes or skins, where it concretes upon cooling. The finest kind is collected at the Missionary Institution at Bethelsdorp, and is hence called *Bethelsdorp aloes*. Its superiority is owing exclusively to the greater care observed in its preparation.

According to *Pharmacographia*, the process just described is still followed in its essential details throughout the Cape. Cape aloes differs from Socotrine aloes especially in its brilliant conchoidal fracture and peculiar odor, which is strong, but neither nauseous nor aromatic. When freshly broken, it has a very dark olive or greenish color approaching to black, presents a smooth bright almost glassy surface, and, if held up to the light, appears translucent at its edges. The small fragments also are semi-transparent, and have a tinge of yellow or red mixed with the deep olive of the opaque mass. The same tinge is sometimes observable in the larger pieces. The powder is of a fine greenish-yellow color, and, being generally more or less sprinkled over the surface of the pieces as they are kept in the shops, gives them a somewhat yellowish appearance. Cape aloes, when quite hard, is very brittle, and readily powdered; but in very hot weather it is apt to become somewhat soft and tenacious, and the interior of the pieces is occasionally more or less so even in winter. It is usually imported in casks or boxes. Dr. Pereira says that a variety is sometimes imported into England from the Cape of a reddish-brown color like hepatic aloes. The use of Cape aloes has greatly lessened; the variety has, in fact, almost disappeared from the American market, the Curaçao aloe having largely taken its place as a cheap aloe. *Natal aloes* is a variety coming from Natal, on the southeast coast of Africa, which occurs in irregular pieces, with a fracture much less shining than that of Cape aloes and a totally different color, having a greenish slate hue. It yields a greenish-brown powder, which has the odor of Cape aloes. It is less soluble than Cape aloes, and has a peculiar composition, which will be adverted to under the chemistry of the drug.

Besides these varieties of aloes, others are mentioned by authors. A very inferior kind, supposed to consist of the dregs of the juice which furnished the better sorts, almost black, quite opaque, hard, of a rough fracture and very fetid odor, and full of various impurities, was formerly sold under the name of *fetid*, *caballine*, or *horse aloes*. It was used exclusively for horses; but, in consequence of the cheapness of better kinds, it has been banished from veterinary practice, and is not now found in the market. Aloes has been imported from Muscat, and a considerable quantity came over in a vessel sent by the Sultan to the United States. Some of a similar origin has been called *Mocha aloes* in London. *Jafferabad aloes*, supposed to be the same as *Mocha aloes* (*A. J. P.*, 1881, p. 175), has been shown to be the product of *A. abyssinica*, and is said by Shenstone to contain β-barbaloïn. (*A. J. P.*, 1883, p. 92.) Aloes made in India from the *A. vulgaris* is known as *Musambra aloes*. It appears to be a very inferior variety, and rarely, if ever, reaches Europe. (*P. J. Tr.*, Aug. 1889.)

General Properties. The odor of aloes is different in the different varieties. The taste is in all of them intensely bitter and very tenacious. The color and other sensible properties have been sufficiently described.* Several distinguished chemists have investigated the

* Hugo Borntträger asserts that one part of aloes in 5000 can be detected in the following manner. A little of the suspected liquid is shaken with about twice its bulk of benzin, which is allowed to separate, decanted, and shaken with a few drops of strongest water of ammonia. On separation the ammonia will be of a clear red color. With solids a tincture should first be made. According to Mr. R. H. Groves (*P. J. Tr.*, 3d ser., xi. 1045), this test will never succeed with a less concentration than 1 part in 250, and with some aloes 1 in 100, and is due to the tannin-like substance of aloes; he also states that extreme care is necessary to have the benzin solution perfectly clear. (*P. J. Tr.*, 1885, p. 633. For Hager's quantitative method for determining the percentage of aloïn in aloes, see *A. J. P.*, 1885, p. 237.)

R. A. Cripps and T. S. Dymond have given the testing of aloes a lengthy investigation, and they recommend the following method. Place 1 grain of the substance in a glass mortar standing on white paper, now add 16 drops of strong sulphuric acid and triturate until dissolved, then add 4 drops of nitric acid, sp. gr. 1·42, and then 1 ounce of distilled water. If aloes be present, a color varying from deep orange to crimson will be produced, according to the kind of aloes that has been used; the color is deepened by the addition of ammonia. The following table is taken

nature and composition of aloes. Braconnot found a bitter principle, which he named *resino-amer* (*resinous bitter*), and another substance in smaller proportion, which he designated by the name of *flea-colored principle*. These results were essentially confirmed by Trommsdorff, Bouillon-Lagrange, and Vogel. Berzelius considers aloes to be made up of a *bitter extractive* and products from this by the alterations in the air. Robiquet obtained a product which he called *aloëtin*. (For details, see 14th ed. U. S. D.)

ALOÏNS. The bitter substances noticed above, viz., the *resino-amer* of Braconnot, the *bitter extractive* of Berzelius and others, and the *aloëtin* of Robiquet, probably contain the active principle of aloes, but combined with impurities which render it insusceptible of crystallization. It is probable that there exists not one compound, but a set of three closely-related compounds, to which the general name of *aloïns* is now given. The first of these, found exclusively in Barbadoes aloes, and discovered by T. and H. Smith, is called *barbaloïn;* the second, discovered by Flückiger in Natal aloes, is called *nataloïn;* the third, found by Histed and Flückiger in Socotrine aloes, is called *socaloïn*.

Barbaloïn. This is a neutral substance crystallizing in tufts of small yellow prisms. These crystals represent hydrated aloïn, and part with one mol. of water (= 2·69 per cent.) by desiccation in vacuo, or by the prolonged heat of a water-bath. Barbaloïn, $C_{17}H_{18}O_7 + \frac{1}{2}H_2O$, dissolves sparingly in water or alcohol, but very freely if either liquid be even slightly warmed; it is insoluble in ether.

By oxidation with nitric acid, barbaloïn yields, as Tilden has shown, about one-third of its weight of *chrysammic acid*, besides aloëtic, oxalic, and picric acids. It combines easily with bromine to form yellow needles of *tribromaloïn*, $C_{17}H_{15}Br_3O_7$; *trichloraloïn*, $C_{17}H_{15}Cl_3O_7$, has also been obtained. (*Pharmacographia*, 2d ed., p. 687.) According to Tilden, from 20 to 25 per cent. of barbaloïn can be extracted from good qualities of the drug by agitating with seven or eight parts of boiling water slightly acidulated with hydrochloric acid, allowing to stand for twenty-four hours, filtering, setting aside for a day or two, putting the resulting mass in a calico bag, and squeezing out the liquid. The barbaloïn thus obtained is purified by solution in alcohol and crystallization. Tilden gives it the formula $C_{16}H_{18}O_7$.

Nataloïn. This exists naturally in Natal aloes, from which it can be easily prepared in the

from the paper of Bainbridge & Morrow (*P. J. Tr.*, Jan. 1890). Under the heading of Kew Specimens are given the results obtained with juice of aloe plants grown in Kew Gardens.

crude state if the drug be triturated with an equal weight of alcohol at a temperature not exceeding 48° C. This will dissolve the amorphous portion, from which the crystals should be separated by a filter and washed with a small quantity of cold spirit. From 16 to 25 per cent. of crude nataloïn in pale yellow crystals may be thus extracted. Its formula is $C_{25}H_{28}O_{11}$. It is scarcely more soluble in warm than in cold spirit of wine, so that to obtain crystals it is best to allow the solution to evaporate spontaneously. Water, hot or cold, dissolves it very sparingly. Nataloïn gives off no water when exposed over oil of vitriol or to a temperature of 100° C. By the action of nitric acid it affords both oxalic and picric acids, but no chrysammic acid.

Socaloïn. In the Socotrine or Zanzibar aloes the crystals are of comparatively large size, such as are not seen in Natal aloes. They cannot, however, be so easily separated as the nataloïn, since they are nearly as soluble as the amorphous matter surrounding them. Histed recommends treating the powdered crude drug with a little alcohol, sp. gr. 0·960, and strongly pressing the pasty mass between several thicknesses of calico, then dissolving the yellow crystalline cake in warm weak alcohol, and collecting the crystals which are formed by cooling and repose. Socaloïn forms tufted acicular prisms, which by solution in methylic alcohol may be obtained 2 to 3 millimetres in length. It is much more soluble than nataloïn. Socaloïn is a hydrate, losing, when dried over oil of vitriol, 11 to 12 per cent. of water, but slowly regaining it if afterwards exposed to the air. Sommaruga gives its composition as $C_{15}H_{16}O_7$.

The three aloïns, *Barbaloïn*, *Nataloïn*, and *Socaloïn*, are easily distinguished by the following beautiful reaction, first noticed by Histed. A drop of nitric acid on a porcelain slab gives, with a few particles of barbaloïn or nataloïn, a vivid crimson (rapidly fading in the case of barbaloïn, but permanent with nataloïn unless heat be applied), but produces little effect with socaloïn. To distinguish barbaloïn from nataloïn, test each by adding a minute quantity to a drop or two of oil of vitriol, then allowing the *vapor* from a rod touched with nitric acid to pass over the surface. Barbaloïn (and socaloïn) will undergo no change, but nataloïn will assume a fine blue. (*Pharmacographia*, 2d ed., p. 688.) E. von Sommaruga and Egger consider that the three aloïns form a homologous series possessing the formulas: barbaloïn, $C_{17}H_{20}O_7$; nataloïn, $C_{16}H_{18}O_7$; socaloïn, $C_{15}H_{16}O_7$, and that they are all derived from *anthracene*, $C_{14}H_{10}$. Tilden subsequently assigned a different composition to the aloïns: barbaloïn and socaloïn, each $C_{16}H_{18}O_7$; for nataloïn, the formula $C_{25}H_{28}O_{11}$. He further states that barbaloïn and socaloïn differ in physical and chemical properties on account of the variation in the molecules of water which are associated with them. The British Pharmacopœia (1898) assigns to barbaloïn the formula $C_{16}H_{16}O_7.3H_2O$. Professor Tschirch, of Berne, Switzerland, published in the *Journal of the German Pharmaceutical Society* (viii., 1898, Heft 6) an important communication, in which he showed that *emodin*, $C_{15}H_{10}O_5$, or *trioxymethylanthraquinone*, is the purgative principle of the aloïns. He succeeded in obtaining emodin in orange-red crystals which melt at 216° C. Emodin was found in the aloïns obtained from Cape, Barbadoes, and Socotrine Aloes; it is extracted by treating barbaloïn with ether, which dissolves out the emodin. Tschirch found that if a liquid extract of aloes be deprived of its resin and aloïn, an additional quantity of emodin could be obtained by boiling the liquid extract with diluted sulphuric acid; thus pointing to the fact that emodin may be produced through hydrolysis. He also showed that emodin could be obtained from purgative drugs of the same class as aloes: rhubarb, rumex, frangula, cascara, senna, rhamnus catharticus, morinda bark, and parmelia. (See *Emodin*, PART II.)

Aloes yields its active matter to cold water, and when good is almost wholly dissolved by boiling water; but the inert portion, or apotheme of Berzelius, is deposited as the solution cools. It is also soluble in alcohol, rectified or diluted. Long boiling impairs its purgative properties by oxidizing the aloïn and rendering it insoluble. The alkalies, their carbonates, and soap alter in some measure its chemical nature, and render it of easier solution. It is inflammable, swelling up and decrepitating when it burns, and giving out a thick smoke which has the odor of the drug.

Those substances only are incompatible with aloes which alter or precipitate the soluble matter; as the insoluble portion is without action upon the system. Among these is the infusion of galls, which we have found, probably through its tannic acid, to afford a copious precipitate with an aqueous solution of aloes. It is said that such a solution will keep a long time, even for several months, without mouldiness or putrescence, though it becomes ropy.

Medical Properties and Uses. Aloes was known to the ancients. It is mentioned in the works of Dioscorides and Celsus, the former of whom speaks of two kinds. The

varieties are similar in their mode of action. They are all cathartic, operating very slowly but certainly, and having a peculiar affinity for the large intestine, and especially its pelvic portion. Their action, moreover, appears to be directed rather to the muscular coat than to the exhalant vessels; and the discharges which they produce are, therefore, seldom very thin or watery. In a full dose they quicken the circulation, and produce general warmth. When frequently repeated, they are apt to irritate the rectum. Aloes has a decided tendency to the uterine system. Its emmenagogue effect, which is often very considerable, is generally attributed to a sympathetic extension of irritation from the rectum to the uterus; but we can see no reason why the medicine should not act specifically upon this organ; and its influence in promoting menstruation is by no means confined to cases in which its action upon the neighboring intestines is most conspicuous. A peculiarity in the action of this cathartic is, that an increase of the quantity administered, beyond the medium dose, is not attended by a corresponding increase of effect. Its tendency to irritate the rectum may be obviated, in some measure, by combining with it soap or an alkaline carbonate; but it does not follow, as supposed by some, that this modification of its operation is the result of increased solubility; for aloes given in a liquid state produces the same effect as when taken in pill or powder, except that it acts somewhat more speedily. Besides, when externally applied to a blistered surface, it operates exactly in the same manner as when internally administered, thus proving that its peculiarities are not dependent upon the particular form in which it may be given, but on specific tendencies to particular parts. (Gerhard, *N. Am. Med. and Surg. Journ.*, x. 155.) With its other powers, aloes combines the property of slightly stimulating the stomach. It is, therefore, in minute doses, an excellent remedy in habitual *costiveness* attended with torpor of the digestive organs. It has been supposed to stimulate the hepatic secretion, and certainly acts sometimes very happily in *jaundice*, producing bilious stools even after calomel has failed. From its special direction to the rectum, it has been found peculiarly useful in the treatment of *ascarides*, and is useful in *hemorrhoids* without inflammation. In *amenorrhœa* it is perhaps more frequently employed than any other remedy, entering into almost all the numerous empirical preparations habitually resorted to by females in that complaint. It is much used in regular practice, and is frequently combined with more irritating cathartics, in order to regulate their liability to excessive action. In *amenorrhœa* it is said to be peculiarly efficacious, when given, in the form of enema, about the period when the menses should appear. Aloes is unsuitable, unless modified by combination, to the treatment of inflammatory diseases.

The medium dose is 10 grains (0·65 Gm.); but as a laxative it will often operate in the quantity of 2 or 3 grains (0·13–0·20 Gm.); and when a decided impression is required, the dose may be augmented to 20 grains (1·3 Gm.). In consequence of its excessively bitter and somewhat nauseous taste, it is most conveniently administered in pills.

ALOE PURIFICATA. U. S. Purified Aloes.

(ĂL'Ọ-Ē PŪ-RĮ-FĮ-CĀ-TĄ.)

Aloès dépuré, *Fr.*; **Gereinigte Aloe**, *G.*

"Socotrine Aloes, *one thousand grammes* [35 ounces av., 120 grains]; Alcohol, *two hundred cubic centimeters* [about 6½ fluidounces]. Heat the Aloes, by means of a water-bath, until it is completely melted. Then add the Alcohol, and, having stirred the mixture thoroughly, strain it through a No. 60 sieve, which has just been dipped into boiling water. Evaporate the strained mixture by means of a water-bath, constantly stirring, until a thread of the mass becomes brittle on cooling. Lastly, break the product, when cold, into pieces of a convenient size, and keep it in well-stoppered bottles." *U. S.* Purified aloes occurs in irregular, brittle pieces of a dull-brown or reddish-brown color, and having the peculiar, aromatic odor of Socotrine Aloes. It is almost entirely soluble in alcohol.

Aloes, even of good quality, is so often mixed as found in the market with various accidental impurities, such as fragments of wood, vegetable remains, pieces of leather, and earthy matter, that it has been thought advisable to have an official process by which it may be freed from these, should its purification be found necessary in any particular instance. The use of alcohol in the formula is simply to render the melted aloes more liquid, and thus facilitate the straining; and it is subsequently got rid of by evaporation; but care should be taken not to use too great a heat, or to continue it too long, for fear of impairing the virtues of the drug. Thus prepared, purified aloes is in irregular, brittle pieces of a dull brown or reddish-brown color, and having the peculiar aromatic odor of Socotrine aloes. It is almost entirely soluble in alcohol.

ALOINUM. U. S., Br. Aloin.

$C_{16}H_{18}O_7$. (ĂL-Ō-Ī'NŬM.)

"A neutral principle obtained from several varieties of Aloes, chiefly Barbadoes Aloes (yielding Barbaloin); and Socotra or Zanzibar Aloes (yielding Socaloin),—differing more or less in chemical composition and physical properties according to the source from which it is derived." *U. S.* "Aloin is extracted from Barbados or Socotrine Aloes by solvents and purified by recrystallization. The products from the different varieties of Aloes possess similar properties. The Aloin extracted from Barbados Aloes has the formula $C_{16}H_{16}O_7,3H_2O$." *Br.*

Although aloïn has been used for many years, it was not recognized by the U. S. Pharmacopœia until the revision of 1890. (See *Aloïns*, p. 139.)

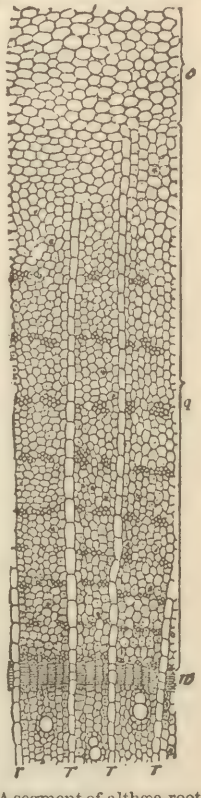
Preparation. Aloïn may be prepared by W. A. Tilden's process as follows. 1 part of aloes is dissolved in 10 parts of boiling water, acidulated with hydrochloric acid, and allowed to cool. The liquid is then decanted from resinous matter, evaporated to about 2 parts, and set aside two weeks for crystals to form; the liquid portion is poured off, the crystals pressed, and the adherent resinous matter separated by shaking with acetic ether, which dissolves the resin. This process answers fairly well for obtaining aloïn from Barbadoes, Curaçoa, or Bonaire aloes. Aloïn from Socotrine aloes is best obtained by digesting the aloes in 3 parts of alcohol for 24 hours, then transferring to a water-bath, and boiling for 2 hours. After cooling, the liquid is filtered and set aside to crystallize. The crystals are washed with a little alcohol and dried. The yield is about 10 per cent. (H. C. Plenge, *A. J. P.*, 1884, p. 507.) Schäfer obtains from 15 to 30 per cent. of crystallized aloïn from commercial aloes by the following process. 50 Gm. of aloes dissolved in 300 C.c. of hot water is slightly acidulated with hydrochloric acid. The solution, after standing (for the resins to separate), is decanted, mixed with 50 C.c. of 20 per cent. ammonia water, followed by a solution of 15 Gm. of calcium chloride in 30 C.c. of water. The liquid is agitated and the aloïn-calcium compound which separates is collected, drained, and mixed in a mortar with a slight excess of hydrochloric acid; the mixture of aloïn and calcium chloride is dissolved in the smallest possible quantity of boiling water, filtered, and the filtrate cooled by means of ice; the aloïn crystallizes. (*P. J. Tr.*, 1897, p. 287.)

Aloïn is officially described as in "minute, acicular crystals, or a microcrystalline powder, varying in color from yellow to yellowish-brown, odorless or possessing a slight odor of aloes, of a characteristic, bitter taste, and permanent in the air. *Barbaloïn* is soluble, at 15° C. (59° F.), in about 60 parts of water, 20 parts of alcohol, or 470 parts of ether. *Socaloïn* is soluble in about 60 parts of water, 30 parts of absolute alcohol, 380 parts of ether, or 9 parts of acetic ether. When heated, Aloïn melts, and, on ignition, it is consumed without leaving a residue. An alcoholic solution of Aloïn is neutral to litmus paper. An aqueous solution of Aloïn is colored greenish-black by ferric chloride test-solution, and slowly precipitated by basic lead acetate test-solution. On adding a minute portion of Barbaloïn to a drop of cold nitric acid of specific gravity 1·200, on a white porcelain surface, a crimson color will be developed. Socaloïn will produce scarcely any color when thus treated. In alkaline solutions, Aloïn is rapidly decomposed; in neutral or acid solutions, only slowly." *U. S.* Aloïn of commerce is frequently contaminated with resin from aloes, indicating want of care in manufacturing. According to Serre (*Drug. Circ.*, 1895, 8), this may be detected by finely powdering 1 grain of the sample, shaking it in a test-tube with 20 C.c. of water, and allowing it to stand one minute. The solution should be perfectly clear. See also paper by C. H. Lawall (*Proc. Penn. Pharm. Assoc.*, 1895, 92).

Medical Properties and Uses. Socaloïn and barbaloïn are active purgatives in doses of 2 to 4 grains. Barbaloïn is affirmed to be the more powerful, and, according to the researches of Hans Moyer (*Arch. Exper. Path. u. Pharm.*, xxviii.), when given hypodermically in dose of four-fifths of a grain (0·05 Gm.), it produces repeated moderate purging in from seven to twenty-two hours. Moyer found that Natal aloïn, though acting energetically upon dogs, usually fails to affect the alvine discharges in man, except when the person has for some days been fed exclusively upon animal food. In combination with belladonna and strychnine, aloïn is one of the most serviceable and pleasantly active laxatives that we have. The ordinary laxative dose may be set down as one-fourth of a grain (0·016 Gm.); the full purgative dose, one grain (0·065 Gm.). Fronmüller (*Lond. Med. Rec.*, 1879, p. 70) affirms that aloïn dissolved in 25 times its weight of water acts as an efficient though slow purgative, when given hypodermically, without causing any local irritation; Moyer found that formamide is an apt vehicle for the hypodermic administration of barbaloïn; in making it, the solution may be warmed, but not heated, for fear of producing ammonia.

ALTHÆA. U.S. Althæa. [Marshmallow.]

(ĂL-THÆ'Ą.)



"The root of Althæa officinalis, Linné (nat. ord. Malvaceæ)." *U. S.*

Radix Althææ, *P. G.;* Racine de Guimauve, Guimauve, *Fr.;* Althiewurzel, Eibischwurzel, Eibisch, *G.;* Altea, *It.,* Altea, Malvavisco, *Sp.*

Gen. Ch. Calyx double, the exterior six- or nine-cleft. *Capsules* numerous, one-seeded. *Willd.*

Althæa officinalis. Willd. *Sp. Plant.* iii. 770; Woodv. *Med. Bot.* p. 552, t. 198. Marshmallow is an herbaceous perennial, with a perpendicular branching root, and erect woolly stems, from two to four feet or more in height, branched and leafy towards the summit. The leaves are alternate, petiolate, nearly cordate on the lower part of the stem, oblong-ovate and obscurely three-lobed above, somewhat angular, irregularly serrate, pointed, and covered on both sides with a soft down. The flowers are terminal and axillary, with short peduncles, each bearing one, two, or three flowers. The corolla has five spreading, obcordate petals, of a pale purplish color. The fruit consists of numerous capsules united in a compact circular form, each containing a single seed. The plant grows throughout Europe, inhabiting salt marshes, the banks of rivers, and other moist places. It is found also in this country on the borders of salt marshes. In some parts of the continent of Europe it is largely cultivated for medical use, particularly in Germany, where, in the neighborhood of Nuremberg and Schweinfurt, about 15 tons are harvested annually. The whole plant abounds in mucilage. The flowers, leaves, and root are mucilaginous, and were formerly official; but the last only is employed to any considerable extent in this country.

The roots should be collected in autumn from plants at least two years old. They are usually prepared for the market by removing the epidermis: commerce is supplied from Europe.

A segment of althæa-root after removal of the starch (after Berg). *w*, cambium layer; *x*, wood; *r*, medullary rays; *q*, bast tissues; *o*, middle bark.

Properties.—Althæa occurs "in cylindrical or somewhat conical pieces, from 10 to 15 Cm. long, 10 to 15 Mm. in diameter, deeply wrinkled; deprived of the brown, corky layer and small roots; externally white, marked with a number of circular spots, and of a somewhat hairy appearance from the loosened bast-fibres; internally whitish and fleshy. It breaks with a short, granular, and mealy fracture, has a faint, aromatic odor, and a sweetish mucilaginous taste." *U. S.* Sections of the root assume a bright yellow tint when an alkali is added to them. Those pieces are to be preferred which are plump and but slightly fibrous. The woody part, on examination with the microscope, is seen to consist of scalariform or pitted vessels, and a few ligneous cells embedded in a loose parenchymatous tissue. The bark is composed of numerous branched liber cells, in bundles of 3 to 30 fibres separated by parenchymatous tissue. The abundant mucilage is situated chiefly in the parenchymatous cells, and can be seen to be in layers when alcohol is added. It, with starch and saccharine matter, is taken out by boiling water. The mucilage, without the starch, is extracted by cold water, which thus becomes ropy. Marshmallow is said to become somewhat acid by decoction. Pieces should be rejected which are woody, discolored, mouldy, of a sour or musty smell, or of a sourish taste. A principle was discovered in the root by M. Bacon, which has been ascertained to be identical with *asparagin*, $C_4H_8N_2O_3 + H_2O$. MM. Boutron-Charland and Pelouze found it to belong to that class of organic principles which are convertible by strong acids, and other agencies, into ammonia and organic acids, and which are designated by the termination *amide*, being compounds of acid radicals with the group NH_2 derived from ammonia by the withdrawal of an atom of hydrogen. When such an amide is acted upon by acids, it is decomposed, the acid radical taking OH to form the free acid and the amide group taking H to form ammonia. Thus asparagin, which in this view should be called *asparamide*, is converted into ammonia and *aspartic acid*, $C_4H_7NO_4$, and one mol. of the resulting ammonium aspartate corresponds with one mol. of asparamide and one of water. (*Journ. de Pharm.*, xix. 208.) Asparagin, being now recognized as a derivative of succinic acid, is called *amido-succinamide*, and the aspartic acid is called *amido succinic* acid. It is

found in various other plants besides the marshmallow, as in the shoots of asparagus, in vetches grown in the dark, in all the varieties of the potato, and in the roots of the comfrey and liquorice plant. According to Professor Pira, asparagin has acid properties. It has no therapeutic value. *Betaine* (trimethyl-glycocoll) has been obtained from althæa by Orlow. (*Pharm. Zeit. für Russland*, 1898.)

The roots of other Malvaceæ are sometimes substituted for that of marshmallow, without disadvantage, as they possess similar properties. Such are those of *Althæa rosea*, or *hollyhock*, and *Malva alcea*. The dark purple flowers of a variety of *A. rosea* have been proposed as a test for acids and alkalies. A strong infusion of these flowers imparts to slips of white filtering paper a permanent purplish-blue color, which is reddened by acids, and rendered bluish green by alkalies.

Medical Properties and Uses. The virtues of marshmallow are exclusively those of a demulcent. The decoction of the root is much used in Europe in irritation and inflammation of the mucous membranes. A syrup of althæa is official in the German Pharmacopœia, and was introduced into the U. S. Pharmacopœia of 1880. The roots themselves, as well as the leaves and flowers, boiled and bruised, are sometimes employed as a poultice. In France the powdered root is much used in the preparation of pills and electuaries.

ALUMEN. U. S., Br. Alum. [Potassium Alum, Aluminum and Potassium Sulphate.]

$Al_2K_2(SO_4)_4 + 24H_2O$; 946·46. (Ă-LŪ'MĔN.) $Al_2K_2(SO_4)_4 + 24H_2O$; 948.

"Aluminium and potassium sulphate (Potassium Alum), $Al_2(SO_4)_3.K_2SO_4.24H_2O$, or aluminium and ammonium sulphate (Ammonium Alum), $Al_2(SO_4)_3.(NH_4)_2SO_4.24H_2O$, produced by the combination of aluminium sulphate with potassium sulphate or with ammonium sulphate." *Br.*

Aluminii et Potassii Sulphas, *U. S.* 1870, Potassa Alum; Sulphas Aluminico-potassicus; Alun, *Fr., Dan., Swed.;* Sulfate d'Alumine et Potasse, *Fr.;* Alaun, *G.;* Allume, *It.;* Allumbre, *Sp.*

Aluminii et Ammonii Sulphas, Sulphas Aluminico-Ammonicus; Alumen, *U. S.* 1870; Ammonia Alum; Alum, *U. S.* 1870; Alun ammoniacal, *Fr.;* Ammoniak Alaun, *G.*

The name alum has been applied indifferently to two salts, one consisting of aluminum tersulphate combined with ammonium sulphate, the other of the same salt of aluminum combined with potassium sulphate, and distinguished as *ammonium-alum* and *potassium-alum*. The former was official in the U. S. P. 1870, but has been replaced by *potassium-alum*. *Ammonium-alum* is still retained with potassium-alum under the title *Alumen* in the British Pharmacopœia.

Alum (Aluminum and Potassium Sulphate. *U. S.* 1890). Potassium-alum is manufactured occasionally from earths which contain it ready formed, but most generally from minerals which, from the fact of their containing most or all of its constituents, are called *alum ores*. The principal alum ores are the *alum stone*, which is a native mixture of aluminum sulphate and potassium sulphate, found in large quantities at Tolfa and Piombino in Italy; certain natural mixtures of iron disulphide with alumina, silica, and bituminous matter, called *aluminous schist* or *alum-slate;* and *cryolite*. (See *Sodii Carbonas.*)

At the Solfatara, and other places in Southern Italy, alum was formerly extracted from earths containing it ready formed. The ground being of volcanic origin, and having a temperature of about 104°, an efflorescence of pure alum formed upon its surface. This was collected and lixiviated, and the solution crystallized by slow evaporation in leaden vessels sunk in the ground. The alum stone is manufactured into alum by calcination, and subsequent exposure to the air for three months; the mineral being frequently sprinkled with water, in order that it may be brought to a soft mass. This is lixiviated, and the solution obtained crystallized by evaporation. The alum stone may be considered as consisting of alum united with a certain quantity of aluminum hydrate. The latter, by the calcination, loses its water, and becomes incapable of remaining united with the alum of the mineral, which is consequently set free. Alum of the greatest purity is obtained from this ore.

Alum-slate, when compact, is first exposed to the air for a month. It is then stratified with wood, which is set on fire. The combustion which ensues is slow and protracted. The sulphur is in part converted into sulphuric acid, which unites with the alumina; and the aluminum sulphate thus formed generates a portion of alum with the potassa derived from the ashes of the wood. The iron, in the mean time, is almost wholly converted into sesquioxide, and thus becomes insoluble. The matter is lixiviated, and the solution crystallized into alum by evaporation. The mother-waters, containing aluminum sulphate, are then drawn off, and

made to yield a further portion of alum by the addition of potassium sulphate or potassium chloride, the latter being obtained from the soap-boilers, or from native potassium chloride of the Stassfurt deposits. When alum-slate is easily disintegrated, it is not calcined, but merely placed in heaps and occasionally sprinkled with water. The iron disulphide gradually absorbs oxygen, and passes into ferrous sulphate, which effloresces on the surface of the heap. Part of the sulphuric acid formed unites with the alumina; so that, after the chemical changes are completed, the heap contains both ferrous sulphate and aluminum sulphate. At the end of about a year, the matter is lixiviated, and the solution of the two sulphates produced is concentrated to the proper degree in leaden boilers. The ferrous sulphate crystallizes, while the aluminum sulphate, being a deliquescent salt, remains in the mother-waters. These are drawn off, and treated with potassium sulphate in powder, heat being at the same time applied. The whole is then allowed to cool, that the alum may crystallize. The crystals are then separated from the solution, and purified by a second solution and crystallization. They are next treated with water just sufficient to dissolve them at the boiling temperature, and the saturated solution is run into casks or tubs so constructed as to be easily taken to pieces and set up again. In the course of ten or fifteen days the alum concretes into a crystalline mass, from which the mother-liquor is let off. The vessel is then taken to pieces, and the salt, having been broken up, is packed in barrels for sale. This process for forming the alum in large masses is called *rocking*.

Alum is now largely manufactured by the direct combination of its constituents. With this view, clays are selected as free from iron and calcium carbonate as possible, and calcined to sesquioxidize the iron and render them more easily pulverizable; after which they are dissolved, by the assistance of heat, in weak sulphuric acid. Advantage has been found from mixing the clay, previous to calcination, with powdered charcoal, coke, or other carbonaceous matter, in the proportion of about one to six of the clay, and then applying heat by a reverberatory furnace till all the carbon is consumed. It is asserted that the alumina is thus rendered more soluble in the acid. (*P. J. Tr.*, Dec. 1857, p. 328.) The aluminum sulphate, thus generated, is next crystallized into alum by the addition of potassium sulphate in the usual manner. Alum is made in this way from the ashes of the Boghead cannel-coal, which occurs near Edinburgh. These ashes, which form the residue of the combustion of the coke derived from the coal used for making gas, contain a considerable quantity of alumina in a state readily soluble in acids. For an account of the manufacture of alum in India, see *Chem. and Drug.*, 1892, 636. *Bauxite*, a hydrated oxide of aluminum, containing from 56 to 60 per cent. of aluminum oxide, has within recent years become one of the most important raw materials for the alum manufacture. It is found in very rich deposits in Georgia and Alabama.

The elements *rubidium* and *cæsium* are found in *lepidolite*, and, as much of the alum in continental Europe is made from this mineral, Salzer found samples of commercial potassium-alum which contained a considerable quantity of rubidium-alum; this contaminated potassium-alum is less soluble in water than ordinary alum. (*Archiv d. Pharm.*, 1887, p. 217.)

The production of alum in the United States in 1896 amounted to 14,090 short tons, valued at $422,700; in 1897, to 15,456 tons, valued at $463,680. The greater part of this was made from American bauxite.

Alumen, *Br.* Aluminii et Ammonii Sulphas. *Sulphate of Aluminium and Ammonium. Ammonia-alum.* Besides the potassium-alum, which is now the only U. S. official variety of this salt, there are several others, in which the potassium is replaced by some other base, as, for example, ammonium or sodium. Of these, *ammonium-alum*, or aluminum and ammonium sulphate, was introduced in the U. S. Pharmacopœia at the revision of 1860; and in the Pharmacopœia of 1870 and Br. Pharmacopœia it was adopted under the name of alumen. It is made by adding ammonium sulphate to the solution of aluminum sulphate. This kind of alum came into very general use, owing to the comparative cheapness of ammonia, obtained in the process for potassium ferrocyanide, or derived from the liquor of gas-works. Ammonium-alum was extensively manufactured by Powers & Weightman, of Philadelphia. *Scotch alum*, made near Paisley, generally contains both potassium and ammonium. Ammonium-alum resembles potassium-alum so exactly that it cannot be distinguished by simple inspection; and in composition it is perfectly analogous to the potassium salt. It may be distinguished by subjecting it to a strong calcining heat, after which alumina will be the sole residue; or by rubbing it with potassa or lime and a little water, when the smell of ammonia will be perceived.

Properties. Alum, as usually seen, is in "large, colorless, octohedral crystals, sometimes modified by cubes, or in crystalline fragments, without odor, but having a sweetish and strongly astringent taste. On exposure to the air, the crystals are liable to absorb ammonia, and acquire a whitish coating. Soluble in 9 parts of water at 15° C. (59° F.), and in 0·3 part of boiling water; it is also freely soluble in warm glycerin, but is insoluble in alcohol. When gradually heated, it loses water; at 92° C. (197·6° F.) it melts, and if the heat be gradually increased to 200° C. (392° F.), it loses all its water of crystallization (45·52 per cent. of its weight), leaving a voluminous, white residue. The salt has an acid reaction upon litmus paper. The aqueous solution of the salt affords, with ammonia water, a white, gelatinous precipitate, which is nearly insoluble in an excess of ammonia. Another portion of the aqueous solution yields, with barium chloride test-solution, a white precipitate, insoluble in hydrochloric acid. When a saturated solution of the salt is actively shaken with tartaric acid test-solution, it affords, within half an hour, a white, crystalline precipitate. The aqueous solution of Alum affords, with potassium or sodium hydrate test-solution, a white, gelatinous precipitate, which is completely soluble in an excess of the alkali, and this alkaline solution should not evolve the odor of ammonia, even when heated (distinction from, and absence of, *ammonium alum*). A 5-per-cent. aqueous solution of the salt should not be affected by hydrogen sulphide test-solution (absence of *copper*, *lead*, or *zinc*), and 20 C.c. of this solution should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide test-solution (limit of *iron*)." *U. S.* "It is soluble in ten times its weight of cold and in one-third of its weight of boiling *water*, the solution having an acid reaction. It is freely soluble in *glycerin*, insoluble in *alcohol* (90 per cent.). It affords the reactions characteristic of aluminium, of potassium or ammonium, and of sulphates. It should yield no characteristic reaction with the tests for copper, lead, zinc, calcium, or sodium, and only the slightest reactions with the tests for iron." *Br.* Its sp. gr. is 1·71. It reddens litmus, but changes the blue tinctures of the petals of plants to green. When heated a little above 100° C. (212° F.), it undergoes the aqueous fusion; and, if the heat be continued, it loses its water, swells up, becomes a white, opaque, porous mass, and is converted into the official *dried alum*. (See *Alumen Exsiccatum*.) Exposed to a red heat, it gives off oxygen, together with sulphurous and sulphuric oxides, and the residue consists of alumina and potassium sulphate. When calcined with finely divided charcoal, it forms a spontaneously inflammable substance, called *Homberg's pyrophorus*, which consists of a mixture of potassium sulphide, alumina, and charcoal.

The characters of ammonium-alum, as stated in the Br. Pharm. (1885), are that its solution gives with caustic potassa or soda a white precipitate, soluble in an excess of the reagent and an immediate precipitate with barium chloride; and does not acquire a blue color from the addition of potassium ferrocyanide or ferricyanide, proving the absence of iron.

Several varieties of alum are known in commerce. *Roche alum*, so called from its having come originally from Rocca, in Syria, is a sort which occurs in fragments about the size of an almond, and of a pale rose color, which is given to it, according to Pereira, by bole or rose-pink. *Roman alum*, which is the purest variety found in commerce, also occurs in small fragments, covered with a reddish-brown powder, resembling ochre, which is put on by the manufacturers. It has been supposed that the powder contains iron; but this is probably a mistake. Roman alum crystallizes in cubes, from the fact that the crystals are deposited from a solution always containing an excess of alumina, which decomposes any iron salt that may be present. This crystalline form of alum is, therefore, an index of its freedom from iron.

All the alums of commerce contain more or less ferrous sulphate, varying from five to seven parts in the thousand. The iron is readily detected by adding to a solution of the suspected alum a few drops of potassium ferrocyanide, which will cause a greenish-blue tint, if iron be present. It may be detected also by precipitating the alumina as a subsulphate with a solution of potassa, and afterwards adding the alkali in excess. This will redissolve the precipitate, with the exception of any iron, which will be left in the state of sesquioxide. The proportion of iron usually present, though small, is injurious when the salt is used in dyeing. Alum may, however, be purified, either by dissolving it in the smallest quantity of boiling water, and stirring the solution as it cools, or by repeated solutions and crystallizations.

Incompatibles. Alum is incompatible with the alkalies and their carbonates, lime and lime water, magnesia and its carbonate, potassium tartrate, and lead acetate.

Composition. Alum was regarded as an aluminum sulphate, until it was proved by Descroizilles, Vauquelin, and Chaptal to contain also potassium sulphate, ammonium sulphate, or both these salts. When its second base is potassium, it consists of one mol. of aluminum sul-

phate 343, one of potassium sulphate 174·2, and twenty-four of water 432 = 949·2. In the ammonium-alum, the molecule of potassium sulphate is replaced by one of ammonium sulphate. *Alumina* is classed as an earth, and may be obtained by subjecting ammonium-alum to a strong calcining heat. It consists of two atoms of a metal called *aluminum* 55, and three of oxygen 48 = 103. It is, therefore, a sesquioxide. The existence of this metal was rendered probable by Sir H. Davy in 1808; but it was not fairly obtained until 1828, when Wöhler procured it in an impure state, in globules of the size of a pin's head, by the action of potassium on aluminum chloride. In 1854, Deville succeeded in obtaining the pure metal in ingots by decomposing the same chloride with sodium. The process of Deville remained the only practical process for its manufacture until 1886, when the Messrs. Cowles, of Cleveland, Ohio, succeeded in effecting the reduction of corundum, the native oxide, by charcoal with the aid of a powerful electric current from a Brush dynamo-electric machine, using large carbon electrodes. They manufactured the pure aluminum and the alloys of copper known as aluminum bronzes. This process in turn has been practically displaced by the Hall process, as operated by the Pittsburg Reduction Company at Niagara Falls and elsewhere. This is to electrolyze pure alumina dissolved in a bath of melted cryolite. The cryolite (a double fluoride of sodium and aluminum) is continuously regenerated, so that by feeding in the pure alumina the process can be made continuous A German process, that of Graetzel, for electrolizing the fused chloride, is also in successful use. Aluminum is silver-white, sonorous, unalterable in the air, and lighter than glass, having only the sp. gr. 2·56. Its fusing point is somewhat lower than that of silver. It is not attacked by sulphuric or nitric acid, nor tarnished by hydrogen sulphide. Its proper solvent is hydrochloric acid. After silver, gold, and platinum, it is the least alterable of the metals.

The production of aluminum in the United States in 1895 was 900,000 lbs., valued at $495,000; in 1896, 1,300,000 lbs., valued at $540,000; and in 1897, 4,000,000 lbs., valued at $1,400,000.

Medical Properties, etc. Alum is a powerful astringent, with very decided irritant qualities, owing to which, when taken internally in sufficient quantity, it is emetic and purgative, and may even cause fatal gastro-intestinal inflammation. It may be employed in passive relaxations of the mucous membranes or skin, *hemorrhages*, *serous diarrhœa*, *colliquative sweats*, etc., but is not much used internally, except in *colica pictonum*. The latter employment of it was introduced by Grashuis, a Dutch physician, in 1752, was imitated by Dr. Percival with great success, and has been revived in recent times with the happiest results. It allays nausea and vomiting, relieves flatulence, mitigates the pain, and opens the bowels with more certainty than any other medicine. Sometimes it is advantageously conjoined with opium and camphor. It is also efficacious in *nervous colic*. Sir James Murray found it a useful remedy in *gastrorrhœa*. He gave it in doses of ten or twelve grains (0·65–0·775 Gm.) three or four times a day, mixed with an equal quantity of cream of tartar to prevent constipation, and a little ginger to obviate flatulence. By Dr. C. D. Meigs alum has been strongly recommended, in doses of a teaspoonful (3·9 Gm.), in *pseudo-membranous croup* as a mechanical emetic, but it is not as certain or powerful as is zinc sulphate.

Alum is a powerful astringent when topically applied, and has been largely used as such. In various *anginas* it has been a favorite remedy, but on account of its destructive influence upon the teeth it should never be used in gargles, but be applied in powder or concentrated solution with the brush. Bretonneau, Vulpian, etc., strongly recommended it in *pseudo-membranous angina*, applied by insufflation in the case of children. When used in the latter way, a drachm of finely powdered alum may be placed in one end of a tube, and then blown by means of the breath into the throat of the child. Alum coagulates blood very rapidly and firmly, and is frequently used as a local styptic in external *hemorrhages* and in *epistaxis* and other bleedings from mucous membranes to which it can be applied directly. In *hæmoptysis* its saturated solution may be used by atomization. It is sometimes applied locally in the form of *cataplasm*, made by coagulating the whites of two eggs with a drachm of alum. In *colica pictonum* from 20 to 30 grains of alum in molasses (or thick syrup) may be given three or four times a day. The emetic dose is one to two teaspoonfuls, repeated, if necessary, in fifteen minutes. An elegant mode of giving alum in solution is in the form of *alum-whey*, made by boiling two drachms of alum with a pint of milk, and then straining to separate the curd. The dose is a wineglassful (60 C.c.), containing about 15 grains (1 Gm.) of alum. As a collyrium, the solution is made of various strengths; as 4, 6, or 8 grains to the fluidounce of water. A solution containing from half an ounce to an ounce in a pint of water, and sweetened with

honey, is a convenient gargle. Solutions for *gleet*, *leucorrhœa*, *ulcers*, etc., must vary in strength according to the state of the parts to which they are applied.*

In a case recorded by Dr. Ricquet, of Liège, death resulted from about an ounce of alum taken in solution by mistake for Epsom salt. A sensation of burning in the mouth, throat, and stomach occurred immediately upon the swallowing of the poison, followed by bloody vomiting, and death in the midst of inexpressible suffering. Upon post-mortem examination there was found a grayish-yellow coating covering the mucous membrane of the mouth, pharynx, and œsophagus; the tongue and uvula were swollen; and the stomach, bowels, and kidneys were injected. (*Journ. de Pharm.*, Oct. 1873, p. 333.)

Alum is sometimes used to adulterate bread, with the view to increase its whiteness and to conceal the defects of the flour. If the quantity used be sufficient, the alum acts as an irritant to the gastro-intestinal tract, and, according to the experiments of Bigelow and Hamilton, it actively checks peptic digestion.

ALUMEN EXSICCATUM. U. S., Br. Dried Alum.

Alumen Ustum, Burnt Alum; Alun calciné, desséché, brûlé, *Fr.*; Gebrannter Alaun, *G.*

"Alum, in small pieces, *one hundred grammes* [or 3 ounces av., 231 grains]. To make *fifty-five grammes* [or 2 ounces av., 10 grains]. Place the Alum in a shallow porcelain capsule so as to form a thin layer, and heat it on a sand-bath until it liquefies. Then continue the application of a moderate heat, with constant stirring, until aqueous vapor ceases to be disengaged, and a dry, white, porous mass is obtained, weighing *fifty-five grammes* [or 2 ounces av., 10 grains]. When cold, reduce the product to a fine powder, and preserve it in well-stoppered bottles." *U. S.*

"Potassium Alum, 4 *ounces* (Imperial) or 100 grammes. Heat the Potassium Alum in a porcelain dish or other suitable vessel till it liquefies, then increase and continue the application of heat until aqueous vapor ceases to be disengaged, and the salt has lost between 45 and 46 per cent. of its weight." *Br.*

The object of these processes is to obtain the alum free from its water of crystallization, without otherwise in the least decomposing it. For this purpose a certain degree of heat is necessary; and yet if the heat be too great the salt itself is decomposed, and the desired end is not attained. If the alum employed be the potassium-alum, the old indefinite directions will generally be sufficient to secure the requisite result, as this salt will resist a heat short of redness; but this is not the case with the ammonium salt, which is official in the Br. P. To guard against failure from this cause, the Pharmacopœias prescribe about 205° C. (400° F.) as the highest heat to be employed, and check the operation when nearly all the water has been driven off, as indicated by the weight of the residue. Prof. John M. Maisch has satisfactorily determined by experiment that, whichever alum may be used, this temperature is quite high enough; and the direction of the Pharmacopœias, as to the weight of the residue, insures that a sufficient heat will be employed. By the official process there is left behind about 4 per cent. of the water of crystallization, when potassium-alum is used.

Properties. Dried alum is officially described as "a white, granular powder, without odor, possessing a sweetish, astringent taste, and attracting moisture on exposure to the air. It is very slowly but completely soluble in 20 parts of water at 15° C. (59° F.), and quickly soluble in 0·7 part of boiling water. Its aqueous solution should respond to the reactions and tests of Alum (see *Alumen*)." *U. S.* Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, alum loses from 41 to 46 per cent. of its weight in dissipated water. Dried alum resists the action of cold water for a long time, showing its altered aggregation. In composition it differs from crystallized alum merely in the absence of water.

Medical Properties and Uses. Dried alum has the same medical properties as ordinary alum, excepting that it is more powerful and irritant. It is used as a mild escharotic to destroy *exuberant granulations*, on which it should be freely dusted.

* Alum enters as an ingredient into the famous *Wickersheimer Preserving Liquid*. The formula, as purchased by the German government from the originator, is as follows. Alum 100 grammes, sodium chloride 25 grammes, potassium nitrate 12 grammes, potassium carbonate 60 grammes, arsenous acid 10 grammes; these are to be dissolved in 3000 grammes (3 liters) of boiling water, the solution allowed to cool, filtered, and to every 10 liters of the liquid 4 liters of glycerin and 1 liter of wood naphtha added. Owing to the precipitation of the alumina in this preparation, it is frequently the practice to substitute for the alum the same quantity of potassium sulphate.

ALUMINI HYDRAS. U. S. Aluminum Hydrate. [Aluminum Hydroxide. Hydrated Alumina.]

$Al_2(HO)_6$; 155·184. (Ą-LŪ'MĮ-NĪ HĪ'DRĂS.) $Al_2(HO)_6$; 156.

Hydrate de l'Alumine, *Fr.;* Thonerdehydrat, *G.;* Argilla Pura, s. Hydrata, *P. G.*

"Alum, *one hundred grammes* [or 3 ounces av., 231 grains]; Sodium Carbonate, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *a sufficient quantity.* Dissolve each salt separately in *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Distilled Water, filter each solution, and heat it to boiling. Then having poured the hot solution of Sodium Carbonate into a capacious vessel, gradually pour in the hot solution of Alum with constant stirring, and add an equal volume of boiling Distilled Water. Let the precipitate subside, decant the clear liquid, and pour upon the precipitate *two thousand cubic centimeters* [or 67 fluidounces, 5½ fluidrachms] of hot Distilled Water. Again decant, transfer the precipitate to a strainer, and wash it with hot Distilled Water, until the washings produce not more than a faint cloudiness with barium chloride test-solution. Then allow it to drain, dry it at a temperature not exceeding 40° C. (104° F.), and reduce it to a uniformly fine powder." *U. S.*

This preparation is identical with the "Alumina Hydrata" of the German Pharmacopœia, and has been introduced probably out of respect to the large number of German practitioners in this country who may use it.

Properties. It is "a white, light, amorphous powder, odorless and tasteless, and permanent in dry air. Insoluble in water or alcohol, but completely soluble in hydrochloric or sulphuric acid, and also in potassium or sodium hydrate test-solution. When heated to redness, it loses about 34·6 per cent. of its weight (water of hydration)." *U. S.*

Tests. "A solution of 1 Gm. of Aluminum Hydrate in 20 C.c. of diluted hydrochloric acid should not at once assume a blue color on the addition of 1 drop of potassium ferrocyanide test-solution (limit of *iron*), and should not give more than a faint cloudiness with barium chloride test-solution (limit of *sulphate*). When dissolved in potassium or sodium hydrate test-solution, it should yield no precipitate with hydrogen sulphide test-solution (absence of *zinc* or *lead*); and when boiled with 20 parts of water, and filtered, the filtrate should not leave more than a slight residue on evaporation (limit of *alkali salts*)." *U. S.*

Medical Properties. This is a very feebly astringent and desiccant powder, sometimes used externally as an application in inflammatory affections of the skin. So far as our experience goes, it is very rarely employed in this country.

ALUMINI SULPHAS. U. S. Aluminum Sulphate.

$Al_2(SO_4)_3.16H_2O$; 628·9. (Ą-LŪ'MĮ-NĪ SŬL'PHĂS.) $Al_2(SO_4)_3.16H_2O$; 630.

Sulfate d'Alumine, *Fr.;* Schwefelsaure Thonerde, *G.*

A process was given in the U. S. P. 1870 for the preparation of this salt,* but the 1880 Committee of Revision very properly omitted the process, merely giving a description and tests for the salt. In the process of 1870, the sodium of the carbonate unites with the sulphuric acid of the aluminum sulphate, with the escape of the carbonic acid, and the precipitation of the aluminum in the form of a hydrate; while the undecomposed ammonium sulphate of the alum, and the newly-formed sodium sulphate, remain in solution. The aluminum hydrate is then washed in order to separate any portion of the sulphates adhering to it, the absence of which is shown by the non-action of barium chloride on the washings. It now remains to unite the aluminum hydrate and sulphuric acid, which is effected by heating them with water; and the salt, which is formed in solution, is obtained by evaporating the solution to dryness. It may also be obtained from the solution by the addition of alcohol, which precipitates it. In the process the several substances are used in very nearly saturating proportions. (See paper on Aluminum Sulphate by Prof. J. U. Lloyd, *N. R.*, Aug. 1879, p. 237.) Aluminum sulphate may be prepared also by the process of MM. Huria and Brunel, which consists in exposing, in an iron cylinder, aluminum and ammonium sulphate (ammonium-alum), first dried to separate its water of crystallization, to a cherry-red heat.

* "Take of Alum, Carbonate of Sodium, each, *four troyounces;* Sulphuric Acid *a troyounce and one hundred and fifty grains;* Water *a sufficient quantity.* Dissolve the salts separately, each in six fluidounces of boiling water, and pour the solution of the Alum gradually into that of the Carbonate of Sodium; then digest with a gentle heat until the evolution of carbonic acid ceases. Collect upon a filter the precipitate formed, and wash it with water, until the washings are no longer affected by chloride of barium. Next, with the aid of heat, dissolve the precipitate in the Sulphuric Acid, previously diluted with half a pint of Water, and, having filtered the solution, evaporate it until a pellicle begins to form. Then remove it to a water-bath, and continue the evaporation, with constant stirring, until a dry salt remains. Lastly, preserve this in a well-stopped bottle." *U. S.* 1870.

Aluminum sulphate remains in the cylinder, and the volatilized products are collected in water. The chief of these is ammonium sulphite, which serves for the preparation of a fresh portion of alum, after having been changed into the sulphate by oxidation in the air. (*Chem. Gaz.*, Sept. 15, 1852, p. 359.) It is now also obtained in enormous quantities, for use in the place of alum as a mordant in dyeing, as one of the by-products in the manufacture of soda from cryolite.

The American production, chiefly from bauxite, in 1896 amounted to 42,240 short tons, valued at $1,056,000; in 1897 it was 46,355 tons, valued at $1,158,875.

Sometimes free sulphuric acid exists in aluminum sulphate. It may be recognized by the salt imparting a strongly acid reaction to alcohol, also by the fact that the dark violet color imparted to decoction of logwood by aluminum sulphate changes to brown in the presence of free acid. (*A. J. P.*, Nov. 1873.) Prof. Wittstein treats the finely powdered salt with absolute alcohol; if the latter does not become acid, no free acid is present. (See also *Proc. A. P. A.*, 1887, p. 216.) Egger recommends Pettenkofer's bile reaction for the detection of free sulphuric acid in aluminum sulphate and alum. (*Chem. News*, 1889, p. 169.)

Properties. As procured by the process of 1870, aluminum sulphate is in the form of a white powder. It may, however, be obtained in lamellar crystals. As seen in commerce, it is usually in flattened crystalline cakes, which appear as though formed by the cooling of soft masses of minute crystals. It has a sour as well as sweet and very astringent taste, is soluble in twice its weight of water, and has an acid reaction.

The salt is "soluble in 1·2 parts of water at 15° C. (59° F.), and much more freely in boiling water, but insoluble in alcohol. When gradually heated to about 200° C. (392° F.), it loses its water of crystallization (45·7 per cent. of its weight). The salt has an acid reaction upon litmus paper. The aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid; and with potassium or sodium hydrate test-solution, a white, gelatinous precipitate which is soluble in an excess of the alkali, but is again separated on the addition of a sufficient amount of ammonium chloride test-solution." *U. S.*

It is formed by the union of one mol. of alumina, which is an aluminum sesquioxide, and three mols. of sulphuric acid, $Al_2(SO_4)_3$, and, when crystallized, contains sixteen mols. of water. The salt is, therefore, an aluminum tersulphate. It is known to be a sulphate by giving a precipitate with barium chloride insoluble in nitric acid, and a salt of aluminum by forming octohedral crystals of alum when its solution is evaporated with potassium or ammonium sulphate. In consequence of its strong affinity for potassa, it is coming into use in the arts as a means of separating that alkali.

Tests. "A filtered, 10-per-cent. aqueous solution of the salt should not be affected by hydrogen sulphide test-solution (absence of *copper*, *lead*, or *zinc*), and should not become more than faintly opalescent within five minutes after the addition of an equal volume of sodium hyposulphite decinormal volumetric solution (limit of *free acid*). 20 C.c. of a 5-per-cent. aqueous solution of the salt should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide test-solution (limit of *iron*). If 1 Gm. of the salt be gently heated with 5 C.c. of potassium or sodium hydrate test-solution, the liquid should not evolve the odor of *ammonia*." *U. S.*

Medical Properties and Uses. The soluble simple salts of aluminum have the property of opposing animal putrefaction, but the sulphate is probably the most powerful and certainly is the most used. It is often employed in solution (℥iiss–f℥vi up to saturation *pro re nata*) as an antiseptic, detergent application to *foul ulcers*, and as an injection in *fetid discharges from the vagina*. M. Homolle employs a saturated solution with much advantage as a mild caustic in *enlarged tonsils*, *nasal polypi*, *nævi*, *scrofulous* and *cancerous ulcers*, *diseases of the os uteri*, and various chronic enlargements. He applies it daily by means of a hair pencil. He has sometimes found the solution to answer still better after the addition of zinc oxide. Solution of aluminum sulphate is capable of dissolving a considerable quantity of recently precipitated gelatinous alumina. Such a solution, impregnated with benzoin, has been proposed by M. Mentel as a hæmostatic, under the name of *benzoinated solution of alumina*. It resembles the *styptic liquid of Pagliari*. It is prepared by saturating with gelatinous alumina a solution made of eight ounces of aluminum sulphate dissolved in a pint of water. To the saturated solution six drachms of bruised amygdaloid benzoin are added, and the whole is kept at a temperature of about 150° F. for six hours, with occasional agitation; so that the liquid, after filtration, may have about the density 1·26. This liquid, put in a cool place for several days, so as to deposit some crystals of alum, forms the benzoinated solution, remarkable

for its very sweet odor and astringent balsamic taste. Benzoinated solution of alumina, diluted in the proportion of from two to five fluidrachms to the pint of water, has been found useful as an injection in *leucorrhœa*, and in *ulcerations of the neck of the uterus*, accompanied by fetid discharges. (See *A. J. P.*, 1857, p. 128.) Aluminum sulphate has been used to preserve cadavers for dissection, but is much inferior to zinc chloride. The solution for injection should be a pound to the quart.

AMMONIACUM. U. S., Br. Ammoniac.

(ĂM-MŌ-NĪ'Ą-CŬM.)

"A gum resin obtained from Dorema Ammoniacum, Don (nat. ord. Umbelliferæ)." *U. S.* "A gum-resin exuded from the flowering and fruiting stem of Dorema Ammoniacum, D. Don; and probably other species." *Br.*

Gummi-resina Ammoniacum; Ammoniacum; Ammoniaque, Gomme-résine ammoniaque, Gomme ammoniaque, *Fr.;* Ammoniak, Ammoniakgummi, *G.;* Gomma ammoniaco, *It.;* Goma amoniaco, *Sp.;* Ushek, *Ar.;* Semugh belsheren, *Pers.*

Much uncertainty long existed as to the ammoniac plant. It was generally believed to be a Ferula, till Willdenow raised, from some seeds mixed with the gum-resin found in the shops, a plant which he ascertained to be a Heracleum, and named *H. gummiferum*, under the impression that it must be the source of the medicine. On this authority the plant was adopted by the British Colleges, and recognized in former editions of our national Pharmacopœia. Willdenow expressly acknowledged that he could not procure from it any gum-resin, but ascribed the result to the influence of climate. The Heracleum, however, did not correspond exactly with the representations given of the ammoniac plant by travellers; and Sprengel ascertained that it was a native of the Pyrenees and never produced gum. Mr. Jackson, in his account of Morocco, imperfectly described a plant of that country, supposed to be a *Ferula*, from which gum-ammoniac is procured by the natives. This plant was ascertained by Dr. Falconer to be *Ferula tingitana* (Royle's *Mat. Med.*), and its product is thought to be the ammoniacum of the ancients, which was obtained from Africa; but this is not the drug now used under that name, which comes exclusively from Persia.* M. Fontanier, who resided many years in Persia, saw the ammoniac plant growing in the province of Fars, and sent a drawing of it with specimens to Paris. From these it was inferred to be a species of Ferula; and Mérat and De Lens proposed for it the name, originally given to it by Lemery, of *F. ammonifera*. It was subsequently, however, ascertained, from specimens obtained in Persia by Col. Wright, and examined by Dr. David Don, that it belonged to a genus allied to Ferula, but essentially different, which was named by Dr. Don *dorema*. It is described in the 16th vol. of the Linn. Transactions, under the name of *Dorema ammoniacum*. This is now acknowledged by the official authorities. The same plant was described and figured by Jaubert and Spack, in their "*Illustrations of Oriental Plants*" (Paris, 1842, t. 40, p. 78), by the name of *Diserneston gummiferum*, under the erroneous impression that it belonged to a previously undescribed genus.

The ammoniac plant grows spontaneously in Farsistan, Irak, Khorassan, and other Persian provinces. Dr. Grant found it abundantly in Syghan near Bamian, on the northwest slope of the Hindoo-Koosh Mountains. It attains the height of six or seven feet, and in the spring and early part of summer abounds in a milky juice, which flows out upon the slightest puncture. From the accounts of travellers, it appears that in the month of May the plant is pierced in innumerable places by an insect of the beetle kind. The juice, exuding through the punctures, concretes upon the stem, and when quite dry is collected by the natives. M. Fontanier states that the juice exudes spontaneously, and that the harvest is about the middle of June. According to Dr. Grant, the drug is collected in Syghan, like asafetida, from the root of the plant. The gum-resin is sent to Bushire, whence it is transmitted to India, chiefly to Bombay. A small portion is said to be taken to the ports of the Levant, and thence distributed. The name of the drug is thought to have been derived from the temple of Jupiter Ammon in the Libyan desert, where the ammoniac of the ancients is said to have been collected; but Dr.

* The *African Ammoniac*, which is said to have appeared in the London market only in the years 1857 and 1871, has been described by Mr. Daniel Hanbury as follows. It is "in large, compact, dark, heavy masses, formed of agglutinated tears of a gum-resin of hard, waxy consistence. The tears are opaque, white or of a pale greenish yellow, mixed with others of a blackish brown, which, with vegetable and earthy impurities, constitute a large portion of the mass." The odor of the drug is feeble, and quite different from that of the Persian gum-resin; its taste slightly acrid and very persistent. (*P. J. Tr.*, March, 1873, p. 741.) Examined by Mr. John Moss, it was found to consist of 67·76 per cent. of resin, 9·014 of gum, 4·29 of water and volatile oil, and 18·85 of bassorin and insoluble matters. (*Ibid.*, p. 742.) It is used chiefly for incense in Mohammedan countries, and sent eastward by the caravans, or in vessels from the ports of Morocco to Alexandria.

Don considers it a corruption of *Armeniacum*, originating in the circumstance that the gum-resin was formerly imported into Europe through Armenia.

Properties. Ammoniac comes either in the state of tears, or in aggregate masses, and in both forms is frequently mixed with impurities. That of the tears, however, is preferable, as the purest may be conveniently picked out and kept for use. These are of an irregular shape, usually more or less globular, from two to eight lines in diameter, opaque, yellowish on the outside, whitish within, compact, homogeneous, brittle when cold, and breaking with a conchoidal, shining, waxy fracture. The masses are often of a darker color and less uniform structure, appearing, when broken, as if composed of numerous white or whitish tears, embedded in a dirty-gray or brownish substance, and frequently mingled with foreign matters, such as seeds, fragments of vegetables, and sand or other earth. According to the U. S. Pharmacopœia, only such masses should be considered up to the standard as are composed entirely of tears "without any intervening dark-colored substance."

The smell of ammoniac is peculiar, and stronger in the mass than in the tears. The taste is slightly sweetish, bitter, and somewhat acrid. The sp. gr. is 1·207. When heated, the gum-resin softens and becomes adhesive, but does not melt. It burns with a white flame, swelling up, and emitting a smoke of a strong, resinous, slightly alliaceous odor. It is partly soluble in water, alcohol, ether, vinegar, and alkaline solutions. Triturated with water it forms an opaque milky emulsion, which becomes clear upon standing. The alcoholic solution is transparent, but is rendered milky by the addition of water. "The freshly fractured surface is colored yellow by *solution of potassium hydroxide*, and dark red or orange by *solution of chlorinated soda*. If a small fragment be strongly heated in a dry test-tube, the contents of the tube, after cooling, yield with boiling *water* a solution which when largely diluted with *water*, and made alkaline with *solution of ammonia*, does not exhibit a blue fluorescence (distinction from asafetida and galbanum)." *Br.* Martius found 0·4 per cent. of ethereal oil, Flückiger 0·33 per cent. (*Pflanzenstoffe*, 2d ed., p. 962.) Plugge's analysis gives 1·27 per cent. of volatile oil, 5·10 per cent. of water, 2 per cent. of ash, 65·53 per cent. of resin, and 26·10 per cent. of gum. Hager succeeded in procuring the volatile oil in a separate state by repeated distillation with water. It has a penetrating disagreeable odor, and a taste at first mild, but afterwards bitter and nauseous. Flückiger says that the oil contains no sulphur. The resin in ammoniacum usually amounts to about 70 per cent. Unlike the gum-resin of allied plants, ammoniacum yields no umbelliferone. When melted with caustic potash it affords protocatechuic acid and resorcin. The resin of ammoniac is dissolved by alcohol, and by the fixed and volatile oils; but it is divided by ether into two resins, of which one is soluble and the other insoluble in ether. P. C. Plugge states that sodium hypobromite, made by dissolving 30 grammes of pure caustic soda in water, adding 20 grammes of bromine, cooling the mixture, and adding distilled water until the whole measures 1 litre, is a sensitive reagent for ammoniac resin. (*Archiv d. Pharm.*, 1883.)

Tschirch and Luz have made an elaborate research of the chemistry of ammoniac, and state the following conclusions. Ammoniac contains resin, gum, and ethereal oil, together with about 3.5 per cent. of a residue insoluble in water and alcohol. The portion soluble in alcohol and ether is a mixture of a so-called acid resin and a neutral resin, and amounts to 69 per cent. Both resins are free from sulphur, despite the statement of Preiszewski, who considered the latter of them to contain sulphur. The saponification of the so-called acid resin yielded salicylic acid of the formulas $C_6H_4OHCOOH$ and $C_6H_4OHCOOH + \frac{1}{2}H_2O$. Along with this were volatile acids, consisting of valeric and butyric acids, and an alcohol which belongs to the class of *resinotannols*, and has the same formula as galbaresinotannol, $C_6H_{10}O$, or $C_{18}H_{30}O_3$. The resin is, therefore, a salicylic ester of resinotannol. From this resinotannol both the acetyl and the benzoyl derivatives were made, and the formula $C_{18}H_{30}O_3$ thus established. On oxidizing the resinotannol with nitric acid, *styphnic acid* was obtained, and on fusing it with caustic potash, resorcin. Ethereal oil was found in small amount only. It contains no umbelliferone, and is free from sulphur. The crude ammoniac showed traces of a free acid which was recognized as salicylic both by its fusing point and the ferric chloride reaction. The gum contained 3·5 per cent. of ash, of which 1·2 per cent. was calcium oxide, so that the gum is probably related to gum arabic, and is an acid calcium arabinate. (*Archiv d Pharm.*, 1895, p. 571.)

Medical Properties and Uses. This gum-resin is stimulant and expectorant, in large doses cathartic, and, like many other stimulants, may be so given as occasionally to prove diaphoretic, diuretic, or emmenagogue. It has been employed in medicine from the highest antiquity, being mentioned in the writings of Hippocrates, but is now seldom administered.

The complaints in which it was most frequently used were *chronic catarrh*, *asthma*, and other *pectoral affections* attended with deficient expectoration without acute inflammation, or with a too copious secretion from the bronchial mucous membrane, dependent upon debility of the vessels. It is usually administered in combination with other expectorants, with tonics, or with emmenagogues. Externally applied, in the shape of a plaster, it is thought to be useful as a discutient or resolvent in white swellings of the joints, and other indolent tumors. (See *Emplastrum Ammoniaci cum Hydrargyro.*) It is given in substance, in pill or emulsion. The latter form is preferable. (See *Emulsum Ammoniaci.*) Dose, ten to thirty grains (0·65–1·95 Gm.).

AMMONII BENZOAS. U. S., Br. Ammonium Benzoate.

$NH_4, C_7H_5O_2$; 138·72. (ĄM-MŌ'NI-Ī BĔN'ZŌ-ĂS.) $NH_4, C_7H_5O_2$; 139.

Ammoniæ Benzoas, Ammonium Benzoicum, Benzoas Ammonicus; Benzoate of Ammonia; Benzoate d'Ammoniaque, *Fr.*; Benzöesaures Ammonium, *G.*

The process for the preparation of this salt was omitted in the 1880 U. S. revision. The process of U. S. 1870 is appended. "Take of Benzoic Acid *two troyounces*; Water of Ammonia *three fluidounces and a half*, or *a sufficient quantity*; Distilled Water *four fluidounces*. Dissolve the Acid in three fluidounces and a half of the Water of Ammonia, previously mixed with Distilled Water; evaporate with a gentle heat, occasionally adding Water of Ammonia, if necessary, to maintain a slight excess of the alkali; then set aside to crystallize, and dry the crystals without heat." "This salt, $C_6H_5.COONH_4$, is produced by neutralizing benzoic acid with solution of ammonia." *Br.*

Although the quantity of ammonia ordered in the formula is in excess, yet, from the feeble affinity between the constituents, and the consequent escape of ammonia during the evaporation, a portion of the acid benzoate would be formed, if it were not that a little solution of ammonia is from time to time added during or near the close of the evaporation, so as to maintain the alkali in slight excess. The crystals, for the same reason, should be dried without heat. If slightly evaporated, and then allowed to cool, the solution becomes a mass of crystals, retaining so much water as to render it necessary to dry them by bibulous paper. "Ammonium Benzoate should be kept in well-stoppered bottles." *U. S.*

Properties. "Thin, white, four-sided, laminar crystals, odorless or having a slight odor of benzoic acid, a saline, bitter, afterwards slightly acrid taste, and gradually losing ammonia on exposure to the air. Soluble, at 15° C. (59° F.), in 5 parts of water, and in 28 parts of alcohol; in 1·2 parts of boiling water, and in 7·6 parts of boiling alcohol. When strongly heated, the salt melts, emits vapors having the odor of ammonia and benzoic acid, and is finally completely dissipated. The salt is neutral, or has a very slightly acid reaction upon litmus paper. A saturated aqueous solution of the salt affords, with ferric chloride test-solution, a flesh-colored precipitate, and, when it is gently heated with potassium or sodium hydrate test-solution, the odor of ammonia is evolved. If diluted nitric acid be added to a 10-per-cent. aqueous solution of the salt, a precipitate of benzoic acid is produced, which, when thoroughly washed, should respond to the tests of purity mentioned under *Acidum Benzoicum*, and the filtrate from this precipitate should not be affected by barium chloride test-solution (absence of *sulphate*), or by silver nitrate test-solution (absence of *chloride*)." *U. S.* "Soluble in 6 parts of cold *water*, in 30 of *alcohol* (90 per cent.), and in 8 of *glycerin*. It affords the reactions characteristic of ammonium salts. An aqueous solution yields a yellowish or flesh-colored precipitate when mixed with *test-solution of ferric chloride*. A strong aqueous solution to which a little *sulphuric acid* is added affords a crystalline precipitate of benzoic acid. It should yield no residue on heating to redness, and no characteristic reaction with the tests for chlorides or sulphates. Its cold aqueous solution does not at once redden *solution of litmus* (absence of acid); on boiling the solution it slowly dissociates into benzoic acid and ammonia, and affords an acid reaction." *Br.* Gmelin states that by boiling its solution the salt is converted into the acid benzoate, which crystallizes in feathery tufts of needles. (*Handbook*, xii. 38.) According to Lichtenstein, it deliquesces in the air. It gives a copious yellow precipitate with ferric salts, and is known to contain benzoic acid and ammonia, by depositing the former when the solution is acidulated with hydrochloric acid, and giving off the latter when it is heated with potassa. According to Mr. Squire, the acid salt which is commonly met with in commerce is less soluble than the official salt, requiring 60 parts of water and 12 of alcohol for solution. This is a decided objection to it.

Medical Properties and Uses. Ammonium benzoate is a slightly stimulant diuretic, which acts chiefly through its benzoic acid; it being decomposed by the gastric acids, which

combine with the ammonia, while the benzoic acid is absorbed, and passes out through the kidneys in the form of hippuric acid. (See *Benzoic Acid.*) The salt has been found useful as a diuretic in *defective action of the kidneys*, as an alterative to the mucous membrane of the urinary passages in chronic inflammation of that tissue, and as a solvent of the *phosphatic deposits*, through the hippuric acid into which it is converted. It has been employed in *gouty affections* with a view to the removal of the deposits of sodium urate about the joints; but it has been shown to have no effect on the elimination of *uric acid*. The salt does not appear to produce injurious effects even in considerable quantities. (Garrod, *Med. Times and Gaz.*, Feb. 1864.) The dose is from ten to thirty grains (0·65–1·95 Gm.), which may be taken dissolved in water.

AMMONII BROMIDUM. U. S., Br. Ammonium Bromide.

NH_4Br; 97·77. (ĄM-MŌ'NI-Ī BRŌ'MI-DŬM.) NH_4Br; 97·8.

"This salt, NH_4Br, is formed by neutralizing hydrobromic acid with a solution of ammonia." *Br.*

Ammonium Bromatum; Bromure d'Ammonium, *Fr.*; Brom-Ammonium, *G.*

Ammonium bromide may be made by dissolving bromine in ammonia water; but the U. S. Pharmacopœia of 1870* preferred the method of first forming ferrous bromide, precipitating with water of ammonia, separating by filtration the ferric oxide, and obtaining by evaporation the ammonium bromide from the solution. This process, it will be seen, is completely parallel with that by which potassium bromide is prepared. According to Prof. Procter, a still better method consists in adding to bromine and water sufficient solution of ammonium sulphide to discharge the color, filtering to separate the sulphur, and then evaporating to dryness. Charles Rice (*A. J. P.*, 1873, p. 249) recommends making ammonium bromide by double decomposition between hot solutions of potassium bromide and ammonium sulphate, assisting the precipitation of potassium sulphate by alcohol. Dr. W. H. Pile (*Proc. A. P. A.*, 1874, p. 434) published a simple process for this salt. Pour the bromine (one pound) carefully into four times its weight of distilled water in a stone jar, add *very gradually* about one quart of solution of ammonia, cover the top of the jar with a glass plate when vapors arise, and when all the ammonia has been added, and the solution is free from the smell of bromine, it is evaporated and the salt granulated; the yield is about twenty ounces.

Properties. Ammonium bromide may be obtained in colorless crystals, but the official salt is a white, crystalline powder. Whether in crystal or in powder, on exposure to the air it gradually becomes yellowish, in consequence of a partial decomposition, by which hydrobromic acid appears to be liberated, as it now changes litmus red. The salt has a saline, pungent taste. Exposed to heat, it sublimes unchanged. It is "soluble, at 15° C. (59° F.), in 1·5 parts of water, and in 30 parts of alcohol; in 0·7 part of boiling water, and in 15 parts of boiling alcohol. When heated, the salt volatilizes completely without melting. The aqueous solution of the salt has a slightly acid reaction upon litmus paper." *U. S.* It is sparingly soluble in ether, and is incompatible with acids, acid salts, and spirit of nitrous ether.

"When the aqueous solution is gently heated with potassium or sodium hydrate test-solution, the odor of ammonia is evolved. If to another portion of the solution a little chloroform be added, and subsequently a few drops of chlorine water, and the whole agitated, the chloroform will acquire a yellowish or yellowish-brown color without a violet tint. If a few drops of diluted sulphuric acid be brought into contact with a little of the powdered salt on a porcelain plate, the salt should not at once assume a yellowish color (absence of *bromate*). A 10-per-cent. aqueous solution should not be affected by hydrogen sulphide test-solution (absence of *metals*), nor by barium chloride test-solution (absence of *sulphate*). 20 C.c. of a 5-per-cent. aqueous solution of the salt should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide test-solution (limit of *iron*). If 3 Gm. of the salt, dried at 100° C. (212° F.), be dissolved in water to the measure of 100 C.c., 10 C.c. of this solution, after the addition of a few drops of potassium chromate test-solution, should require not more than 30·9 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red coloration

* "Take of Bromine *two troyounces*; Iron, in the form of wire and cut in pieces, *a troyounce*; Water of Ammonia *four fluidounces and a half*; Distilled Water *a sufficient quantity*. Add the Iron and then the Bromine to half a pint of Distilled Water, contained in a glass flask having the capacity of two pints; loosely cork the flask, and agitate the mixture until the odor of Bromine can no longer be perceived, and the liquid assumes a greenish color. Mix the Water of Ammonia with half a pint of Distilled Water, and add it to the mixture in the flask; agitate the mixture, and heat it by means of a water-bath for half an hour; then filter, and, when the liquor ceases to pass, wash the precipitate on the filter with boiling distilled water. Evaporate the solution, in a porcelain capsule, until a pellicle begins to form, then stir it constantly with a glass rod, at a moderate heat, until it granulates." *U. S.* 1870.

(absence of more than 1 per cent. of *ammonium chloride*)." *U. S.* "0·5 gramme of the dry salt dissolved in *water* should require not more than 51·8 and not less than 51·1 cubic centimetres of the *volumetric solution of silver nitrate* for complete precipitation (limit of impurities). It should yield no residue on being heated to redness, no characteristic reaction with the tests for lead, iron, bromates, iodides, or nitrates, and not more than the slightest reactions with the tests for sulphates or chlorides." *Br.*

Medical Properties and Uses. This bromide resembles potassium bromide in its physiological powers, but has a less depressing effect upon the arterial and muscular systems. It is certainly superior to potassium bromide in most cases of *epilepsy* and even of minor *neuroses*. The dose is from one to two drachms a day (3·9–7·8 Gm.) in dilute solution.

AMMONII CARBONAS. U. S., Br. Ammonium Carbonate.

$NH_4HCO_3.NH_4NH_2CO_2$; 156·77. (ĄM-MŌ'NĮ-Ī CĂR'BO-NĂS.) $NH_4HCO_3.NH_4NH_2CO_2$; 157.

"A variable mixture of ammonium hydrogen carbonate, NH_4HCO_3, with ammonium carbamate, $NH_4NH_2CO_2$, produced on heating ammonium sulphate or chloride with calcium carbonate." *Br.* "Ammonium Carbonate should be kept in well-stoppered bottles, in a cool place." *U. S.*

Ammoniæ Carbonas, *Br.*, 1867; Ammoniæ Sesquicarbonas, *Lond.; Dub.;* Ammonium Carbonicum, *P.G.;* Carbonas Ammonicus, Sal Volatile Siccum; Volatile Salt, Sal Volatile; Carbonate d'Ammoniaque, Alkali volatil concret, Sal volatil d'Angleterre, *Fr.;* Kohlensaures Ammonium, Flüchtiges Langensalz, Reines Hirschhornsalz, *G.*

There have been many methods of obtaining ammonium carbonate, in all of which the ammonia originated in organic decomposition. It was probably originally prepared from putrid urine, and it is sometimes made in Scotland now from this source. A patent was taken out in England for manufacturing it from guano, and another for making it by the direct combination of its constituents; the carbonic acid and ammoniacal gases being introduced simultaneously into leaden chambers. (*Chem. News*, Dec. 29, 1865.) But at present the salt is manufactured by subliming a mixture of either the chloride or the sulphate with chalk. Ammonium chloride and chalk (calcium carbonate) are heated together in iron pots or retorts, and sublimed into large earthen or leaden receivers. By the reciprocal action of the salts employed, the carbonic acid of the chalk unites with the ammonia of the chloride, generating ammonium carbonate, and the hydrochloric acid with the lime, forming water and calcium chloride. The carbonate and water sublime together as hydrated ammonium carbonate, and the residue is calcium chloride. The relative quantities of chalk and ammonium chloride, for mutual decomposition, are 50 of the former and 53·5 of the latter, or one mol. of each. But a great excess of chalk is usually taken, in order to insure the perfect decomposition of the ammonium chloride, any redundancy of which would sublime with the carbonate and render it impure.

Ammonium sulphate may be substituted for the chloride with much economy, as was shown by Payen. This double decomposition between ammonium sulphate and calcium carbonate takes place in the dry way only,—that is, by sublimation. In the wet way, the double decomposition is reversed; ammonium carbonate and calcium sulphate reacting so as to form ammonium sulphate and calcium carbonate. Large quantities of this carbonate are manufactured indirectly from *coal-gas liquor* and *bone-spirit;* the ammoniacal products in these liquors being converted successively into ammonium sulphate, chloride, and carbonate. (See *Ammonii Chloridum.*) The salt as first obtained has a slight odor of tar, and leaves a blackish carbonaceous matter when dissolved in acids. Hence it requires to be purified, which is effected in iron pots surmounted with leaden heads. The American carbonate has almost supplanted the English article, formerly exclusively used.

Properties. Commercial ammonium carbonate, recently prepared, is in white, translucent masses, consisting of Ammonium Bicarbonate (Acid Carbonate) and Carbamate, losing both ammonia and carbonic acid gas on exposure to air, becoming opaque and finally converted into friable porous lumps, or a white powder (Acid Ammonium Carbonate). The salt has a pungent ammoniacal odor, free from empyreuma, a sharp, saline taste, and an alkaline reaction. "Slowly but completely soluble in about 5 parts of water at 15° C. (59° F.); decomposed by hot water with the elimination of carbonic acid and ammonia. By prolonged boiling with water the salt is completely dissipated. Alcohol dissolves the Carbamate [$NH_4NH_2CO_2$], and leaves the acid carbonate (ammonium bicarbonate). When heated, the salt is completely volatilized, without charring. The aqueous solution possesses a strongly alkaline reaction, and effervesces with acids. A 5-per-cent. aqueous solution of the salt, slightly supersaturated with acetic acid, should not be affected by the hydrogen sulphide test-solution (absence of *metals*),

nor by barium chloride test-solution (*sulphate*), or ammonium oxalate test-solution (*calcium*). A 5 per cent. aqueous solution, on the addition of a slight excess of silver nitrate test-solution, and subsequent supersaturation with nitric acid, should neither assume a brown color (absence of *hyposulphite*), nor become more than slightly opalescent within two minutes (limit of *chloride*). If 1 Gm. of the salt be slightly supersaturated with nitric acid, and the solution evaporated to dryness on a water-bath, it should afford a colorless and odorless residue, which, upon gentle ignition, should be completely volatilized (absence of *empyreumatic* or *non-volatile matters*). If 7·84 Gm. of unaltered Ammonium Carbonate be dissolved in water to the volume of 90 C.c., 30 C.c. of this solution (containing 2·613 Gm. of the salt) should require, for exact neutralization, *fifty* (50) *cubic centimeters* of normal sulphuric acid (each C.c. corresponding to 2 per cent. of the pure salt), rosolic acid being used as indicator." *U. S.* "Exposed to the air it becomes covered with a white efflorescence which should be only superficial; this should be scraped off before the salt is used for dispensing purposes. It affords the reactions characteristic of ammonium salts and of carbonates. Each gramme dissolved in 40 cubic centimetres of *water* should require for neutralization at least 18·7 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no residue on being heated to redness, and not more than the slightest reactions with the tests for chlorides or sulphates. When its aqueous solution is neutralized with an acid and evaporated to dryness, the residue should be colorless and odorless (absence of tarry matters)." *Br.* If commercial ammonium carbonate be treated with 90 or 91 per cent. alcohol, it is decomposed into the two salts of which it is composed, ammonium carbamate going into solution while the acid ammonium carbonate remains undissolved. This latter compound also remains undissolved when the commercial carbonate is treated with an amount of water insufficient for complete solution. The result of the complete solution of the commercial salt in water is a mixture of acid and neutral carbonates, the carbamate having been decomposed according to the reaction $(NH_4)HCO_3 + CO\left\{\begin{matrix}ONH_4\\NH_2\end{matrix}\right. + H_2O = (NH_4)HCO_3 + (NH_4)_2CO_3$. When long or insecurely kept, it gradually passes into the state of bicarbonate, becoming opaque and friable, and falling into powder. When heated on a piece of glass, the commercial carbonate should evaporate without residue, and, if turmeric paper held over it undergoes no change, it has passed into bicarbonate. As prepared from coal-gas liquor, it sometimes contains traces of tarry matter, which give a dark color to its solution in acids, but a refined carbonate, made by resubliming the commercial article, is now in the market, and this alone should be dispensed in preparations for internal use. When it is saturated with nitric acid, neither barium chloride nor silver nitrate causes a precipitate. The non-action of these tests shows the absence of ammonium sulphate and chloride. It is decomposed by acids, the fixed alkalies and their carbonates, lime water and magnesia, solution of calcium chloride, alum, acid salts such as potassium bitartrate and bisulphate, solutions of iron (except the iron and potassium tartrate and analogous preparations), corrosive sublimate, lead acetate and subacetate, and ferrous and zinc sulphates. Traces of chlorine have been noticed in some samples of commercial carbonate, and a sublimed salt which had been sold as carbonate, was *devoid of odor*, hard, crystalline, yet having the external appearance of carbonate, and was proved by Prof. Bridges to be anhydrous ammonium bicarbonate. (*A. J. P.*, Nov. 1874). Although much inferior to the official compound, this salt is frequently found in the market. For a paper by G. M. Beringer on testing commercial ammonium carbonate, see *A. J. P.*, 1890, p. 500; see one also by Charles C. Abbey, *Pharm. Era*, 1889, p. 417.

Composition. This salt, which used to be considered an ammonium sesquicarbonate of the formula $2(CO_3(NH_4)H) + CO_3(NH_4)_2 + H_2O$, is now generally recognized as a mixture of either one or two mols. of acid ammonium carbonate, $(NH_4)HCO_3$, with one mol. of ammonium *carbamate*, $CO\left\{\begin{matrix}ONH_4\\NH_2\end{matrix}\right.$. When the salt is dissolved in water, the reaction given above converts it into a mixture of acid and neutral carbonates, and when water of ammonia is added in sufficient amount it converts the acid carbonate into neutral carbonate, which is used frequently as a laboratory reagent, or by passing carbonic acid gas into a solution of the commercial salt the whole may be converted into acid carbonate or bicarbonate.

Medical Properties and Uses. Locally applied ammonium carbonate is an irritant, and when taken internally in sufficient amount it acts as an irritant poison. When administered in therapeutic doses it is a powerful cardiac stimulant, acting not so rapidly and fugaciously as the solutions of ammonia, but still in a very prompt and temporary manner. It is

employed in low conditions of the system as a stimulant, but it should always be remembered that its influence lasts for only a short time, and that there is reason for believing that when continuously given it is apt to impair the crasis of the blood. It is probably eliminated in part by the lungs, and certainly is a stimulant to the respiratory centres. It seems also to exert some influence upon the pulmonary mucous membrane, and is largely employed in *adynamic pneumonias* and *bronchitis*, in the last stages of *phthisis*, etc. In some of these cases it does good by increasing muscular power and aiding in the expulsion of the sputa.

Coarsely bruised with the addition of half its bulk of strongest water of ammonia, and scented with oil of lavender, it constitutes the common smelling-salts, so much used as a nasal stimulant in *syncope* and *hysteria*.* The ordinary dose is five grains (0·33 Gm.), given in mixture, and repeated at not longer intervals than two hours. It should never be given in powder or in pill, on account of its volatile nature and its irritant action on mucous membranes.

Ammonium carbonate is sometimes employed to make effervescing draughts, 20 grains of the salt requiring for this purpose 6 fluidrachms of lemon-juice, 24 grains of citric acid, or 25½ grains of tartaric acid.

AMMONII CHLORIDUM. U. S., Br. Ammonium Chloride.

NH_4Cl; 53·38. (ĄM-MŌ'NI-Ī ĊHLŌ'RI-DŬM.) NH_4Cl; 53·4.

"This salt, NH_4Cl, may be formed by neutralizing crude solution of ammonia or ammonium carbonate with hydrochloric acid, and purifying the product." *Br.*

Muriate of Ammonia, Ammonia Muriaticum s. Hydrochloratum, Chloruretum Ammonicum, Sal Ammoniacum, Ammoniæ Hydrochloras s. Murias; Sal Ammoniac, Hydrochlorate of Ammonia; Hydrochlorate d'Ammoniaque, Muriate d'Ammoniaque, Sel Ammoniac, Chlorure d'Ammonium, Chlorure d'Ammonium pur; Ammonium Muriaticum Depuratum, Sal Ammoniacum Depuratum, *Fr.;* Ammonium Chloratum, *P. G.;* Salmiak Chlorammonium; Reiner (gereinigter) Salmiak, *G.;* Sale Ammoniaco, *It.;* Sal Amoniaco, *Sp.*

In the Pharmacopœia of 1870 both the crude and the purified ammonium chloride were official, under the names *Ammonii Chloridum* and *Ammonii Chloridum Purificatum*. The Pharm. 1890 recognizes but one, *Ammonii Chloridum*, but it transfers this title, which formerly was given to the crude sal ammoniac, to the purified salt, without giving a process for preparing it.† It originally came from Egypt, where it was obtained by sublimation from the soot resulting from the burning of camels' dung, which is used in that country for fuel, and it is still to be found in the Indian bazaars in an impure state as it has been obtained from the unburnt extremity in the interior of brick-kilns in which camels' manure is used for fuel. It has long been known in China, where it is obtained from the water of certain volcanic springs, and exists in commerce in various states of purity. It is found in the fumeroles of Vesuvius, Etna, Hecla, and other volcanoes, as well as in the cracks and fissures in recent lava-streams.

Preparation. At present ammonium chloride is derived from two principal sources, the ammoniacal liquor, called *gas liquor*, found in the condensing vessels of coal-gas works, and the brown, fetid ammoniacal liquor, known under the name of *bone-spirit*, which is a secondary product, obtained from the destructive distillation of bones, in the manufacture of bone-black. These two liquors are the chief sources of ammoniacal compounds; for they are both used to procure ammonium chloride, and this salt is employed directly or indirectly for obtaining all the other salts of ammonia. Other sources are stale urine, coal soot, guano, peat, and bituminous schist.

Gas liquor contains ammonium carbonate, cyanide, sulphide, and sulphate, but principally the carbonate. It is saturated with sulphuric acid, and the solution obtained, after due evaporation, furnishes brown crystals of ammonium sulphate. These are then sublimed with sodium chloride in iron pots lined with clay and furnished with a leaden dome or head. By the mutual action of the sulphate, water, and chloride, there are formed ammonium chloride which sublimes, and sodium sulphate which remains behind. Thus $(NH_4)_2SO_4$ and $(NaCl)_2$

* In Mounsey's recipe for the English *Preston salts*, the essence to be added to the carbonate is made as follows. Take oil of cloves ℥ss; oil of lavender ℥j; oil of bergamot ℥iiss; stronger water of ammonia (sp. gr. 0·880) f℥x. Mix. The bottles are to be filled with ammonium carbonate, half with the salt coarsely bruised, and the remainder with it in fine powder; and then as much of the above essence as the salt will absorb is to be added. (*P. J. Tr.*, xiii. 628.)

† The process (Pharm. 1870) for purifying sal ammoniac is here given as found in 14th ed. U. S. D.

"Take of Chloride of Ammonium, in small pieces, *twenty troyounces;* Water of Ammonia *five fluidrachms;* Water *two pints*. Dissolve the Chloride of Ammonium in the water, in a porcelain dish, with the aid of heat; add the Water of Ammonia, and continue the heat for a short time; filter the solution while hot, and evaporate to dryness, with constant stirring at a moderate heat, until it granulates." *U. S.* 1870.

The object of this process is to free the drug from ferric chloride, which is a frequent impurity of the crude salt, derived from the subliming vessels.

become $(NH_4Cl)_2$ and Na_2SO_4. Gas liquor is at present usually distilled with lime with the aid of column stills, whereby a relatively pure and strong ammonia is obtained. This may be further purified, however, from empyreumatic matter by treatment with potassium permanganate and then driven over by heat and absorbed in hydrochloric acid. In this way, as the solution becomes concentrated, the sal ammoniac crystallizes out in the bottom of the leaden tanks in which the absorption takes place. Impure sal ammoniac may be purified either by crystallization or by sublimation. In the latter case the sal ammoniac is placed in an iron subliming pot coated with a composition of clay, sand, and charcoal and covered with a dome of lead. These pots are sometimes sufficiently large to hold five hundred pounds. "A gentle fire is kept up under the subliming pot for seven or eight days, when, the dome having cooled down, and the sal ammoniac somewhat contracted, so as to loosen from the sides, the dome is thrown off from the iron pot, and about two or three hundred-weight of white, semi-transparent sal ammoniac are knocked off in cakes." (Pereira, *Mat. Med.*, 3d ed., p. 446.)

In the destructive distillation of bones for making bone-black, the distilled products are the bone-spirit already mentioned, being chiefly an aqueous solution of ammonium carbonate, and an empyreumatic oil, called *animal oil*. Ammonium chloride may be obtained from the bone-spirit in the manner just described for procuring it from gas liquor. Sometimes, however, the ammonium sulphate is not made by direct combination, but by digesting the bone-spirit with ground plaster of Paris. By double decomposition, ammonium sulphate and calcium carbonate are formed. The ammonium sulphate is then converted into the chloride by sublimation with common salt. The chloride "may be formed by neutralizing hydrochloric acid with ammonia or carbonate of ammonium, and evaporating to dryness." *Br.*

Other processes have been proposed or practised for obtaining ammonium chloride. For an account of the manufacture of ammoniacal salts, and for a list of the patents issued in Great Britain, since 1827, for their preparation, the reader is referred to the *P. J. Tr.*, xii. 20, 63, 113.

Commercial History. Nearly all the ammonium chloride used in the United States is obtained from abroad. Its commercial varieties are known under the names of the *crude* and the *refined*. The crude is imported from Calcutta in chests containing from 350 to 400 pounds, and is consumed almost exclusively by coppersmiths and other artisans in brass and copper, for the purpose of keeping metallic surfaces bright, preparatory to brazing. The refined comes to us exclusively from England, packed in casks containing from 5 to 10 cwt.

Properties. Commercial ammonium chloride is a white, translucent, tough, fibrous salt, occurring in large cakes about two inches thick, convex on one side and concave on the other, due to the shape of the dome of the subliming apparatus: the pieces frequently are tinged on the surface with iron stains, owing to the contact with the iron dome. It has a pungent, saline taste, but no smell. Its sp. gr. is 1·45. This salt is very difficult to powder in the ordinary way. Its pulverization, however, may be readily effected by making a boiling saturated solution of the salt and stirring it as it cools. The salt is thus made to granulate, and in this state, after having been drained from the remaining solution and dried, may be easily powdered. At a red heat it sublimes without decomposition, and without residue. Exposed to a damp atmosphere it becomes slightly moist. It has the property of increasing the solubility of corrosive sublimate in water. It is decomposed by the strong mineral acids, and by the alkalies and alkaline earths,—the former disengaging hydrochloric acid, the latter ammonia, both sensible to the smell. Ammonium chloride is usually employed for obtaining gaseous ammonia, which is conveniently disengaged by lime. It is incompatible with lead acetate and silver nitrate, producing precipitates respectively of lead and silver chlorides.

Ammonium chloride is little subject to adulteration. If not entirely volatilized by heat, and if insoluble in water, it contains impurity. Still, as ordinarily prepared, it contains ferrous chloride. This metal may be detected by boiling a small portion of a saturated solution of the salt with a drop or two of nitric acid, and then adding potassium ferrocyanide, when the characteristic blue color occasioned by iron will be produced. If the salt is entirely volatilized by heat, and yet produces a precipitate with barium chloride, the presence of ammonium sulphate is indicated. The description and tests of the official salt are as follows:

"A white, crystalline powder, without odor, having a cooling, saline taste, and permanent in air. Soluble in three parts of water at 15° C. (59° F.), and in 1 part of boiling water, but almost insoluble in alcohol. On ignition, the salt is completely volatilized, without charring. The aqueous solution of the salt is neutral to litmus paper, and affords, with silver nitrate test-solution, a white, curdy precipitate, which is soluble in ammonia water. Another portion of

the aqueous solution, when gently heated with potassium or sodium hydrate test-solution, evolves the odor of ammonia. A 5-per-cent. aqueous solution of the salt should not be affected by hydrogen sulphide test-solution (absence of *metals*), barium chloride test-solution (*sulphate*), diluted sulphuric acid (*barium*), or ammonium oxalate test-solution (*calcium*). When acidulated with hydrochloric acid, the solution should not assume a red color on the addition of a few drops of ferric chloride test-solution (absence of *sulphocyanate*). 20 C.c. of a 5-per-cent. aqueous solution of the salt should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide test-solution (limit of *iron*). If to 1 Gm. of the salt a little nitric acid be added, and the mixture evaporated to dryness in a porcelain capsule on a water-bath, a white residue should be obtained which, when more strongly heated, should be completely volatilized (absence of *empyreumatic* or *non-volatile matters*)." *U. S.* "It should yield no residue on being heated to redness, and no characteristic reaction with the tests for lead, copper, arsenium, calcium, carbonates, or nitrates, and only the slightest reactions with the tests for iron, or for sulphates. Its aqueous solution should not give a blood-red coloration with *test-solution of ferric chloride* (absence of thiocyanates)." *Br.*

Composition. Ammonium chloride consists of one atom of chlorine and one of ammonium, $(\dot{N}H_4) = NH_4Cl$. Viewed as *hydrochlorate of ammonia* or *muriate of ammonium*, it is composed of one mol. of hydrochloric acid and one of ammonia.

Medical Properties. Ammonium chloride has the stimulant properties of ammonia, and probably differs little in its physiological powers from the carbonate, but it is believed by many to be less fugacious in its action and to be less stimulant to the circulation than is the latter salt. Clinical experience has also led to a somewhat particular use of it in diseases. It is one of the most employed of the stimulant expectorants in the advanced stages of *acute bronchitis* and in *chronic bronchitis*, also in *catarrhal pneumonia*. It has been very highly recommended of late years in *chronic hepatic torpor and engorgement*, and even in *acute hepatitis*, by Dr. W. Stewart, who gives 20 grains of it three times a day and continues its use for weeks. We have seen *catarrhal jaundice* apparently very much benefited by it. Many years ago it was a favorite remedy as a resolvent in *chronic glandular enlargements*, but at present it is rarely so employed. There is much testimony as to the value of ammonium chloride in certain obscure nervous affections, especially *hemicrania*, *ovaralgia*, *dysmenorrhœa*, *sciatica*, and various other neuralgic disorders. The usual expectorant dose of the chloride is 5 to 10 grains (0·33–0·65 Gm.) every two hours, administered in sweetened mucilage; but formerly in *prostatic* and other *glandular enlargements* it was recommended to increase the dose until half an ounce a day was ingested. When such amounts are given, the remedy is prone to produce disordered digestion, a miliary eruption, profuse sweats, and scorbutic symptoms.

Externally, ammonium chloride is used in solution, as a stimulant and resolvent, in *contusions*, *indolent tumors*, etc. An ounce of the salt dissolved in nine fluidounces of water and one of alcohol forms a solution of convenient strength. When the solution is to be used as a wash for *ulcers*, or as an injection in *leucorrhœa*, it should not contain more than from one to four drachms of the salt to a pint of water. A pediluvium consisting of half a pound of ammonium chloride dissolved in water, followed by fomentations with the same solution, is said to have cured *senile gangrene*. (*Annuaire de Thérap.*, 1868.)

The vapor of ammonium chloride has been administered by inhalation, employed several times a day, in *chronic catarrh*, with marked advantage, by Dr. Giescler, of Germany. Dr. Hermann Beigel, of London, strongly recommends its inhalation in the nascent state, resulting from a mixture of the two gases composing it. Three bottles are used, one containing ammonia water, the second an equivalent quantity of liquid hydrochloric acid, and the third half filled with water, connected with the first two by tubes, and supplied itself with a tube for inhalation. By inhalation the patient draws the two gases from their respective bottles into the third, where they combine to form ammonium chloride, which is freed from any excess of either gas by the water. Another mode of inhaling ammonium chloride is in *spray*, by means of the atomizer; from 10 to 20 grains are dissolved for the purpose in a fluidounce of water.

AMMONII IODIDUM. U. S. Ammonium Iodide.

NH_4I; 144·54. (ĄM-MŌ'NĮ-Ī Ī-ŎD'Į-DŬM.) NH_4I; 144·6.

Iodure d'Ammonium, *Fr.*; Ammonium jodatum, Ioduretum Ammonicum, Jodammonium, *G.*

"Ammonium Iodide should be kept in small, well-stoppered vials, protected from light. When deeply colored, the salt should not be dispensed, but it may be deprived of free iodine

by adding to its concentrated aqueous solution sufficient ammonium sulphide test-solution to render it colorless, then filtering, and evaporating on a water-bath to dryness." *U. S.*

No process is given in the Pharm. 1890 for this salt; that of the Pharm. 1870 will be found below.*

This salt was formerly prepared according to the method of Mr. John A. Spencer, of London, the formula for which is as follows. Add to a portion of iodine, placed in a flask with a little water, a solution of ammonium sulphydrate, until the mixture loses its red color, and is turbid from the separation of sulphur only. Shake the flask, which causes the sulphur, for the most part, to agglomerate; and, having poured off the liquid, boil it until all odor of hydrogen sulphide and of ammonia is lost. Then filter the liquid, and, constantly stirring, evaporate it, first with a naked flame until it becomes pasty, and then in a water-bath until it forms a dry salt. In 1864 (*A. J. P.*, May, 1864), Dr. Jacobson proposed a plan in which double decomposition between the ammonium sulphate and the potassium iodide was brought about. Mr. James F. Babcock (*Proc. A. P. A.*, 1866) stated that on trial of the first of the above processes, and of all others in which hydrogen sulphide or an alkaline sulphide was employed, the resulting ammonium iodide retained a portion of sulphur, which caused its color to change with time to yellow and ultimately to brown, and rendered it unfit for the accurate preparations required in photography. Having tried also other formulas, which he found objectionable, he at length satisfied himself that the process of Dr. Jacobson above described was the best in use, and with slight modifications would yield an absolutely pure product.

In a former edition of the Dispensatory may be found the exact process finally adopted by Mr. Babcock. It is substantially that which was official in Pharm. 1870, and is in close accord with that of Dr. Jacobson. The object of the first step of the process is sufficiently evident. After the double decomposition has occurred, the alcohol is added to complete the precipitation of the potassium sulphate; the pouring of alcohol upon the cotton filter is to remove completely from the sulphate all of the iodide. As made by this process, ammonium iodide always contains a minute proportion of potassium sulphate. Charles Rice (*A. J. P.*, 1873, p. 249) calls attention to the fact that the process official in U. S. Pharm. 1870 is deficient in the amount of ammonium sulphate required, and therefore wasteful of the more expensive iodide; instead of one ounce of ammonium sulphate the quantity should be 867 grains. The view taken by Mr. Rice, however, is that the reaction takes place between single molecules of the respective salts, which is no doubt correct, whereas the view of the Pharmacopœia committee was that two mols. of the iodide reacted with one of ammonium sulphate, $2KI + (NH_4)_2SO_4 = K_2SO_4 + 2NH_4I$.

Properties. Ammonium iodide is in "minute, colorless, cubical crystals, or a white granular powder, without odor when colorless, but emitting a slight odor of iodine when colored, and having a sharp, saline taste. The salt is very hygroscopic, and soon becomes yellow or yellowish-brown on exposure to the air and light, owing to the loss of ammonia and the elimination of iodine. Soluble, at 15° C. (59° F.), in 1 part of water, and in 9 parts of alcohol; in 0·5 part of boiling water, and in 3·7 parts of boiling alcohol. When heated on platinum foil, it evolves vapor of iodine, and volatilizes completely without melting. The aqueous solution of the salt is neutral to litmus paper, and, when gently heated with potassium or sodium hydrate test-solution, evolves the odor of ammonia. If a little chloroform be added to 10 C.c. of the aqueous solution, then a few drops of chlorine water, and the whole agitated, the chloroform will acquire a violet color. A solution of 1 Gm. of the salt in 20 C.c. of water, acidulated with a few drops of diluted hydrochloric acid, should not afford an immediate cloudiness or precipitate with 5 drops of barium chloride test-solution (limit of *sulphate*). A 1-per-cent. aqueous solution of the salt should not at once assume a blue color with potassium ferrocyanide test-solution (limit of *iron*), nor, after being mixed with a little starch test-solution, should it assume a deep blue color (limit of *free iodine*). If 0·25 Gm. of the salt be dissolved in 10 C.c. of ammonia water, the solution then shaken with 19 C.c. of silver nitrate decinormal volumetric solution, and the filtrate supersaturated with 5 C.c. of nitric acid, no cloudiness

* "Take of Iodide of Potassium, in coarse powder, *four troyounces*; Sulphate of Ammonium, in coarse powder, a *troyounce* [this should be 867 grains]; Boiling Distilled Water *two fluidounces*; Alcohol, Water, each, a *sufficient quantity*. Mix the salts, add them to the Boiling Water, stir well, and allow the mixture to cool; then add a fluidounce of Alcohol, mix well, and reduce the temperature, by a bath of iced water, to about 40°; throw the mixture into a cool glass funnel, stopped with moistened cotton, and, when the clear solution has passed, pour upon the salt a fluidounce of a mixture containing two parts of Water and one part of Alcohol. Lastly, evaporate the solution rapidly to dryness, stirring constantly; and preserve the residue in a well-stopped bottle." *U. S.* 1870.

should make its appearance within ten minutes (absence of more than about 0·5 per cent. of *chloride* or *bromide*)." *U. S.*

Medical Properties. Ammonium iodide is employed, both externally and internally, as a resolvent, and resembles closely, in its action, iodine and potassium iodide. Dr. B. W. Richardson, of London, has prescribed it, in the dose of from one to three grains, with considerable success, in *secondary syphilis*, *chronic rheumatism*, *incipient phthisis*, and in a variety of forms of *scrofulous disorder*, attended with glandular enlargements. Dr. Richardson found a liniment, made by dissolving half a drachm of the iodide in an ounce of glycerin, very efficacious in *enlarged tonsils*, applied every night with a large camel's-hair brush, and his practice has been followed to some extent by other members of the profession.* Externally, this salt has been used as a substitute for potassium iodide. By Dr. Pennock it is considered a good remedy in certain cases of *lepra* and *psoriasis*, in the form of ointment, applied by friction in the quantity of half an ounce, morning and evening. The proportions employed are from a scruple to a drachm of the salt to an ounce of lard; the weaker preparation being used when the disease is recent, the stronger when it is chronic. As the iodide is decomposed by the air, the ointment should be kept in well-stopped bottles. For internal use the dose of ammonium iodide is from three to five grains (0·20–0·33 Gm.).

AMMONII NITRAS. U. S. Ammonium Nitrate.

NH_4NO_3; 79·9. (ĄM-MŌ'NĮ-Ī NĪ'TRĂS.) NH_4NO_3; 80.

Ammoniæ Nitras, *Br.*, 1867; Nitrate of Ammonia; Ammonium Nitricum, Nitrum Flammans; Azotate d'Ammoniaque, Nitre inflammable, Nitre ammoniacal, Sal ammoniacal nitreux, *Fr.*; Salpetersaures Ammon, Ammonium, Ammoniak, *G.*

An extraordinary property possessed by this salt of absorbing ammoniacal gas, and giving it out again at a moderate heat unchanged, renders it capable of useful pharmaceutical application; but the chief cause of its introduction into the U. S. Pharmacopœia was its being the source whence nitrogen monoxide is produced.

Ammonium nitrate may be prepared by treating commercial ammonium carbonate by nitric acid so long as effervescence takes place, or to saturation, filtering, and evaporating the solution. By careful evaporation and slow refrigeration the salt may be obtained in well-defined crystals. If crystallized after rapid concentration by boiling and sudden cooling, it forms long flexible and elastic threads. If the solution be heated till all the water is driven off and the fused mass kept at a temperature not exceeding 320° F. (160° C.), the commercial fused salt is produced. It may also be made by double decomposition between solutions of ammonium sulphate and potassium nitrate.

Properties. "Colorless crystals, generally in the form of long, thin, rhombic prisms, or in fused masses, without odor, having a sharp, bitter taste, and somewhat deliquescent. Soluble, at 15° C. (59° F.), in 0·5 part of water, and in 20 parts of alcohol; very soluble in boiling water, and in 3 parts of boiling alcohol. When gradually heated, it melts at 165°–166° C. (329°–330·8° F.); at a temperature between 230° and 250° C. (446°–482° F.) it is decomposed into nitrogen monoxide gas and water, leaving no residue. The aqueous solution of the salt is neutral to litmus paper, and, when gently heated with potassium or sodium hydrate test-solution, it evolves the odor of ammonia. On heating the salt with sulphuric acid, it emits nitrous vapors." *U. S.*

At all temperatures between —15° C. (5° F.) and 25° C. (77° F.), if exposed to a current of dry ammoniacal gas, its crystals absorb the gas and melt, yielding a colorless liquid, which, if the absorption has taken place at —10° C. (14° F.), contains two mols. of the gas for each mol. of the salt, and would be represented by the formula $NH_4NO_3 + 2NH_3$. It is not frozen by a mixture of salt and snow. Its sp. gr. is 1·05. Heated moderately it boils, with loss of ammonia, and is changed into a crystalline mass, containing 21·25 parts of the gas in 100 of the salt by weight, and corresponds with the formula $NH_4NO_3 + NH_3$, thus retaining one-half the gas absorbed. By exposure to increased heat, this loses ammonia, and at 80° C. (176° F.) has been reconverted to pure ammonium nitrate. This preparation may be used for obtaining small quantities of pure ammonia, when wanted, by exposing it to a gentle heat in

* Theodore G. Davis (*A. J. P.*, 1877, p. 305) gives a formula for *Liniment of Iodide of Ammonium* which he says closely corresponds with a proprietary liniment largely sold at one time; but it cannot be regarded as correctly named, for it contains a small quantity of iodide in a *pint* of liniment. Water of Ammonia 10 per cent. f℥ij, Soap Liniment f℥ij, Tinct. Iodine f℥viij, Alcohol f℥iv. Mix the soap liniment with the tincture of iodine, and add the alcohol and ammonia; shake, and add alcohol to make 1 pint. Let it stand two or three days before using.

a small retort. To be fit for this purpose, it must be kept at a low temperature. (*P. J. Tr.*, June, 1872.)

Tests. "A 10-per-cent. aqueous solution of the salt, when acidulated with nitric acid, should not be affected by silver nitrate test-solution (absence of *chloride*), nor by barium chloride test-solution (absence of *sulphate*)." *U. S.*

For the mode of preparing nitrogen monoxide (hyponitrous oxide), or nitrous oxide gas, from ammonium nitrate, the reader is referred to the article on Nitrogen Monoxide in Part II. of this work.

AMMONII PHOSPHAS. Br. Phosphate of Ammonium.

$(NH_4)_2HPO_4$; 132. (ĄM-MŌ'NI-Ī PHŎS'PHĂS.)

"A salt, $(NH_4)_2HPO_4$, which may be obtained by neutralizing phosphoric acid with solution of ammonia." *Br.*

Ammoniæ Phosphas; Phosphate of Ammonia; Ammonium Phosphoricum, *P.G.;* Phosphas Ammonicus; Phosphate d'Ammoniaque, *Fr.;* Phosphorsaures Ammoniak, *G.*

This salt was introduced into the 1880 U. S. Pharm., but was dropped at the late revision.

The variety of phosphoric acid employed in this formula is the tribasic, which forms three salts with ammonia, one containing three atoms of ammonium without basic hydrogen, which is called the neutral phosphate, the second, two mols. of ammonium and one of basic hydrogen, forming an acid phosphate, and the third, one mol. of ammonium and two of basic hydrogen, forming also an acid phosphate. The second of these is the one intended by the U. S. and British Pharmacopœias, and is represented by the formula $(NH_4)_2HPO_4$. To prepare it, a constant excess of ammonia must be maintained, and this is done by compliance with the process, if the materials are of due strength. Without such a precaution, more or less of the more acid phosphate would be generated, in consequence of the escape of the alkali.

Properties. Hydrogen di-ammonium phosphate, which is the official salt, occurs in "colorless, translucent, monoclinic prisms, losing ammonia on exposure to dry air, without odor, having a cooling, saline taste and a neutral or faintly alkaline reaction. Soluble in 4 parts of water at 15° C. (59° F.), in 0·5 part of boiling water, but insoluble in alcohol. When strongly heated, the salt fuses, afterwards evolves ammonia, and at a bright red heat is wholly dissipated." *U. S.* 1880. The salt commonly found in commerce is either this acid phosphate, or a mixture of the two acid salts. The official salt may be made by saturating the excess of acid in acid calcium phosphate by means of ammonium carbonate. Calcium phosphate is precipitated and ammonium phosphate obtained in solution, which, being duly concentrated by a gentle heat, affords the salt in crystals upon cooling. The method of obtaining the acid calcium phosphate is given under the head of sodium phosphate. (See *Sodii Phosphas.*) Ammonium phosphate prepared in this way is a white salt, crystallizing in six-sided tables, derived from oblique quadrangular prisms, efflorescent, insoluble in alcohol, and soluble in 4 parts of cold water. The solution has an alkaline somewhat saline taste, and an alkaline reaction, and gives out ammonia when heated.

The other acid phosphate, $NH_4H_2PO_4$, is obtained by boiling a solution of either of the other salts so long as ammonia escapes, and then crystallizing. Its crystals are four-sided prisms, permanent in the air, of an acid taste and reaction, and soluble in 5 parts of cold water. (*Bridges.*) In a specimen of the common ammonium phosphate of commerce which came under our notice, we recognized both the tabular crystals of the phosphate with two mols. of ammonium, having a saline slightly acrid taste, and neutral in reaction, and the prisms of the acid salt, with a sour and saline taste and a decidedly acid reaction.

Tests. "The aqueous solution of the salt, when heated with potassa, evolves vapor of ammonia. Addition of test-solution of nitrate of silver to the aqueous solution produces a canary-yellow precipitate, soluble in nitric acid and in ammonia. The aqueous solution should remain unaffected by sulphide of ammonium, or, after being acidulated with hydrochloric acid, by hydrosulphuric acid (abs. of metals), or by test-solution of chloride of barium (sulphate). When acidulated with nitric acid, it should not be rendered turbid by test-solution of nitrate of silver (chloride). 2 Gm. of the salt dissolved in water and precipitated with test-mixture of magnesium, yields a crystalline precipitate, which, when washed with diluted water of ammonia, dried, and ignited, should weigh 1·68 Gm." *U. S.* 1880. This quantitative test is intended as a means of identifying the hydrogen di-ammonium salts. The British Pharmacopœia gives the following quantitative test. "When 2 grammes are dissolved in *water*, and *solution of magnesium ammonio-sulphate* is added in excess, a crystalline precipitate should be formed, which, after being well washed upon a filter with *solution of ammonia* diluted with an equal

volume of *water*, and then dried and heated to redness, weighs 1·68 grammes. Its aqueous solution should yield no characteristic reaction with the tests for lead, copper, or arsenium, and only the slightest reactions with the tests for iron, chlorides, or sulphates." The amount of the residue, which is magnesium pyrophosphate, indicates the quantity of phosphoric acid contained in the salt.

Medical Properties and Uses. This salt was first brought to the notice of the profession, as a remedy for *gout* and *rheumatism*, by Dr. T. H. Buckler (*Am. Journ. Med. Sci.*, 1846), and has since been so employed with apparently useful results. The dose is from ten to forty grains (0·65–2·6 Gm.), three or four times a day, dissolved in a tablespoonful of water.

AMMONII VALERIANAS. U. S. Ammonium Valerianate.

$NH_4C_5H_9O_2$; 118.78. (ĄM-MŌ'NĮ-Ī VĄ-LĒ-RĮ-Ā'NĂS.) $NH_4C_5H_9O_2$; 119.

Valérianate d'Ammoniaque, *Fr.*; Baldriansaures (Valeriansaures) Ammonium, *G.*

A process for preparing this salt is no longer official; that of the Pharm. 1870 is found below.*

Ammonium valerianate was introduced into the U. S. Pharmacopœia of 1860; much difficulty was experienced by manufacturing chemists in procuring a crystallized ammonium valerianate, until, after a series of experiments, Mr. B. J. Crew, of Philadelphia, ascertained that it was necessary to employ the *monohydrated* valerianic acid, as the ordinary acid with three mols. of water could not be successfully used for the purpose. The official formula of 1870 was based upon that of Mr. Crew, published in the *A. J. P.* (1860, p. 109). In this formula the monohydrated valerianic acid, procured by a special process (see *Acidum Valerianicum*), is saturated with gaseous ammonia obtained in the usual manner from a mixture of ammonium chloride and lime. The saturation is known to have been effected when litmus paper is no longer acted on. During the operation heat is developed sufficient to prevent premature crystallization, and, when the saturation is completed, nothing more is necessary than to allow the solution to cool. Crystallization soon begins, and in a few hours the contents of the vessel become a nearly solid mass of crystals; these should be thoroughly drained, and, without unnecessary exposure, at once transferred to well-stoppered bottles.

Properties. Thus prepared, ammonium valerianate is in snow-white, pearly, four-sided, tabular crystals, perfectly dry, of an offensive odor like that of valerianic acid, and a sharp sweetish taste. Instead of liquefying whenever exposed to the air, as happened to the salt formerly procured, it undergoes this change only in a moist atmosphere, and effloresces when the air is dry. It is very soluble in water, ether, and alcohol. Exposed to heat it is in great measure volatilized unchanged; but a small portion, by giving off a part of its ammonia, is converted into the acid valerianate. Hager (*Pharm. Centralb.*, 1879, p. 465) states that commercial ammonium valerianate is always the acid salt, as is proved by the acid reaction and the strong rotation of the crystals when placed upon cold water; the neutral salt is obtained only with difficulty, is in prismatic crystals, and is easily liquefied by moderate temperatures. Its formula is $NH_4C_5H_9O_2$. "The aqueous solution has an acid reaction, and, when gently heated with potassium or sodium hydrate test-solution, it evolves the odor of ammonia. If a concentrated aqueous solution of the salt be slightly supersaturated with sulphuric acid, an oily layer of valerianic acid will separate on the surface. A 5-per-cent. aqueous solution, when acidulated with nitric acid, should not be affected by barium nitrate test-solution (absence of *sulphate*), nor by silver nitrate test-solution (absence of *chloride*). If a neutral solution of the salt be completely precipitated with ferric chloride test-solution, the filtrate should not possess a deep red color (absence of *acetate*)." *U. S.*

Medical Properties. Ammonium valerianate is not poisonous. Given to dogs in the dose of 150 grains, it produced no inconvenience. As a therapeutic agent it was first brought to the notice of the profession, in 1856, by M. Déclat, of Paris. The preparation which he used was a solution of ammonium valerianate of uniform strength, made according to the recipe of M. Pierlot, an apothecary of Paris. Since then it has been used in various diseases, princi-

* "Take of Valerianic Acid *four fluidounces*; Chloride of Ammonium, Lime, each, *a sufficient quantity*. From a mixture of Chloride of Ammonium, in coarse powder, and an equal weight of Lime, previously slaked and in powder, contained in a suitable vessel, obtain gaseous ammonia, and cause it to pass, first through a bottle filled with pieces of Lime, and afterwards into the Valerianic Acid, in a tall, narrow, glass vessel, until the Acid is neutralized. Then discontinue the process, and set the vessel aside that the Valerianate of Ammonium may crystallize. Lastly, break the salt into pieces, drain it in a glass funnel, dry it on bibulous paper, and keep it in a well-stopped bottle." *U. S.*

pally of the nervous system, such as *hysteria*, *epilepsy*, *chorea*, *neuralgia*, and is certainly useful in various mild functional nervous affections, but in such grave maladies as epilepsy it is powerless. The dose of the salt is from two to eight grains (0·13–0·52 Gm.), dissolved in water. As now prepared, it may be made into pills without inconvenience; and, properly coated so as to conceal their disagreeable odor, they are probably the best form for the administration of the salt. *Pierlot's solution*, mentioned above, should be made by dissolving a drachm of valerianic acid in thirty-two drachms of distilled water, saturating the solution with ammonium carbonate, and adding to the salt formed two scruples of the alcoholic extract of valerian. According to M. Pierlot, the latter addition is necessary in order to preserve the preparation from change; for a simple solution of the ammoniacal salt is rapidly decomposed. It will keep still better if the extract, when added to the solution, be mixed with a fluidounce of diluted alcohol, while but 24 drachms of distilled water are used, so as to preserve the measure. The solution of M. Pierlot is neutral, of a brown color, and a strong odor of valerian. It contains 1-25th of its weight of the pure salt. The dose is from six to thirty drops (0·36–1·9 C.c.), given in water or on a lump of sugar. (*Ann. de Thérap.*, 1857, p. 55.)

AMYGDALA AMARA. U. S., Br. Bitter Almond.

(Ą-MĬG'DĄ-LĄ Ą-MĀ'RĄ.)

"The seed of Prunus Amygdalus, var. amara, De Candolle (nat. ord. Rosaceæ)." *U. S.*
"The ripe seed of Prunus Amygdalus, Stokes, var. amara, Baillon." *Br.*

Amygdalæ Amaræ, *P. G.;* Semen Amygdali Amarum; Amande amère, *Fr.;* Bittere Mandeln, *G.;* Mandorle amare, *It.;* Almendra amarga, *Sp.*

Bitter Almonds. These are smaller than the sweet almonds, and are thus described in the U. S. Pharmacopœia. "About 25 Mm. long, oblong-lanceolate, flattish, covered with a cinnamon-brown, scurfy testa, marked by about sixteen lines emanating from a broad scar at the blunt end. The embryo has the shape of the seed, is white, oily, consists of two plano-convex cotyledons, and a short radicle at the pointed end, and has a bitter taste. When triturated with water, Bitter Almond yields a milk-white emulsion, which emits an odor of hydrocyanic acid." *U. S.* They have the bitter taste of the peach kernel, and, though when dry inodorous or nearly so, have, when triturated with water, the fragrance of the peach blossom. They contain the same ingredients as sweet almonds, and like them form a milky emulsion with water. It was formerly supposed that they also contained hydrocyanic acid and volatile oil, to which their peculiar taste and smell and their peculiar operation upon the system were ascribed. It was, however, ascertained by MM. Robiquet and Boutron that these principles do not pre-exist in the almond, but result from the reaction of water; and Wöhler and Liebig proved, what was suspected by Robiquet, that they are formed out of a peculiar substance denominated *amygdalin*, which is the characteristic constituent of bitter almonds. This substance, which was discovered by Robiquet and Boutron in 1830, is white, crystallizable, inodorous, of a sweetish bitter taste, unalterable in the air, freely soluble in water and hot alcohol, very slightly soluble in cold alcohol, and insoluble in ether. It is decomposed by the action of dilute acids or in the presence of water by the nitrogenous ferments, like emulsin, which accompany it in the bitter almond. The reaction is as follows:

$$\underset{\text{Crystallized amygdalin.}}{C_{20}H_{27}NO_{11}} + 3H_2O = 2\underset{\text{Dextro-glucose.}}{(C_6H_{12}O_6)} + \underset{\text{Hydrocyanic acid.}}{HCN} + \underset{\text{Oil of bitter almonds.}}{C_7H_6O} + H_2O.$$

It is recognized as belonging to the *glucoside* class, compounds which, when decomposed by dilute acids, alkalies, or ferments, yield glucose and some other characteristic decomposition product. They may be considered as compound ethers of glucose analogous to the compound ethers of glycerin which exist in the fats under the name of *glycerides*. Liebig and Wöhler give the following process for obtaining amygdalin, in which the object of the fermentation is to destroy the sugar with which it is associated. Bitter almonds, previously deprived of their fixed oil by pressure, are to be boiled in successive portions of alcohol till exhausted. From the liquors thus obtained all the alcohol is to be drawn off by distillation; care being taken, near the end of the process, not to expose the syrupy residue to too great a heat. This residue is then to be diluted with water, mixed with good yeast, and placed in a warm situation. After the fermentation which ensues has ceased, the liquor is to be filtered, evaporated to the consistence of syrup, and mixed with alcohol. The amygdalin is thus precipitated in connection with a portion of gum, from which it may be separated by solution in boiling alcohol, which will deposit it upon cooling. If pure, it will form a perfectly transparent solution with

water. Any oil which it may contain may be separated by washing with ether. One pound of almonds yields at least 120 grains of amygdalin. (*Annal. der Pharm.*, xxii. 329.)*

Amygdalin, mixed with emulsion of *sweet* almonds, gives rise, among other products, to the volatile oil of bitter almonds and hydrocyanic acid,—the emulsion of the sweet almonds acting the part of a ferment, by causing a reaction between the amygdalin and water; and the same result is obtained when pure *emulsin* is added to a solution of amygdalin. It appears, then, that the volatile oil and hydrocyanic acid developed in bitter almonds when moistened result from the mutual reaction of amygdalin, water, and emulsin. Certain substances have the effect of preventing this reaction, as, for example, alcohol and acetic acid. It is asserted that emulsin procured from other seeds, as those of the poppy, hemp, and mustard, is capable of producing the same reaction between water and amygdalin, though in a less degree. (*Annal. der Pharm.*, xxviii. 290.) Amygdalin appears not to be poisonous when taken pure in the stomach, unless there be emulsin in the food in the stomach.

Bitter almonds yield their fixed oil by pressure, and at the present time this oil is an article of commerce, and is frequently sold as oil of sweet almonds, being produced in England from North African bitter almonds; the volatile oil, impregnated with hydrocyanic acid, may be obtained from the residue by distillation with water. (See *Oleum Amygdalæ Amaræ.*)

Confectioners employ bitter almonds for communicating flavor to orgeat syrup. (See *Syrupus Amygdalæ.*) The kernel of the peach possesses similar properties, and is frequently used as a substitute. It has been ascertained that bitter almond paste, and other substances which yield the same volatile oil, such as bruised cherry-laurel leaves, peach leaves, etc., have the property of destroying the odor of musk, camphor, most of the volatile oils, creosote, cod-liver oil, the balsams, etc.; and M. Mahier, a French pharmacist, has employed them successfully to free mortars and bottles from the odor of asafetida and other substances of disagreeable smell. All that is necessary is first to remove any oily substance by means of an alkali, and then to apply the paste or bruised leaves.

Medical Properties and Uses. (See *Amygdala Dulcis.*)

AMYGDALA DULCIS. U.S., Br. Sweet Almond.

(Ą-MĬG'DĄ-LĄ DŬL'CĮS.)

"The seed of Prunus Amygdalus, var. dulcis, De Candolle (nat. ord. Rosaceæ)." *U. S.*

"The ripe seed of Prunus Amygdalus, Stokes, var. dulcis, Baillon. It is known in commerce as the Jordan almond." *Br.*

Amygdalæ Dulces, *P. G.;* Semen Amygdali Dulce; Amande douce, *Fr.;* Süsse Mandeln, *G.;* Mandorle dolci, *It.;* Almendra dulce, *Sp.*

Gen. Ch. *Calyx* five-cleft, inferior. *Petals* five. *Drupe* with a nut perforated with pores. *Willd.*

Amygdalus communis. Willd. *Sp. Plant.* ii. 982; Woodv. *Med. Bot.* p. 507, t. 183. The almond tree rises usually from fifteen to twenty feet in height, and divides into numerous spreading branches. The leaves stand upon short footstalks, are about three inches long and three-quarters of an inch broad, elliptical, pointed at both ends, veined, minutely serrated, with the lower serratures and petioles glandular, and are of a bright green color. The flowers are large, of a pale red color varying to white, with very short peduncles, and petals longer than the calyx, and usually stand in pairs upon the branches. The fruit is of the peach kind, with the outer covering thin, tough, dry, and marked with a longitudinal furrow, where it opens when fully ripe. Within this covering is a rough shell, containing the kernel or almond.

There are several varieties of this species of Amygdalus, differing chiefly in the size and shape of the fruit, the thickness of the shell, and the taste of the kernel. The two most important are *Amygdalus* (*communis*) *dulcis* and *Amygdalus* (*communis*) *amara*, the former bearing sweet, the latter bitter almonds. Another variety is the *fragilis* of De Candolle, which yields the *paper-shelled almonds.* The almond-tree is a native of Persia, Syria, and Barbary, and is extensively cultivated in the south of Europe. It has been introduced into the United States; but in the northern and middle sections the fruit does not come to perfection. We are

* Amygdalin appears to be extensively diffused in plants, having been noticed not only in the different genera of the Amygdalæ, as *Amygdalus, Cerasus,* and *Prunus,* but also by Wicke in various Pomaceæ, as *Pyrus malus, Sorbus aucuparia, Sorbus hybrida, Sorbus torminalis, Amelanchier vulgaris, Cotoneaster vulgaris,* and *Cratægus oxyacantha.* (*Ann. d. Chem. und Pharm.*, lxxix. 79.) It may be advantageously procured from peach kernels, which have been found to yield 80 grains for each avoirdupois pound, or more than 1 per cent. (*A. J. P.*, xxvii. 227.) According to the researches of Johannen, the emulsin is contained in the radicle and plumule, and in the vascular bundles of the cotyledons, while the parenchyma of the cotyledons contains the amygdalin. (*P. J. Tr.*, March, 1888.)

supplied with sweet almonds chiefly from Spain and the south of France. They are separated into the soft-shelled and hard-shelled, the former of which come from Marseilles and Bordeaux, the latter from Malaga. From the latter port they are sometimes brought to us without the shell. In British commerce, the two chief varieties are the *Jordan* and *Valencia* almonds, the former imported from Malaga, the latter from Valencia.* The former are longer, narrower, more pointed, and more highly esteemed than the latter. The bitter almonds are obtained chiefly from Morocco, and are exported from Mogador.

Properties. The shape and appearance of almonds are too well known to require description. Each kernel consists of two white cotyledons, enclosed in a thin, yellowish-brown, bitter skin, which is easily separable after immersion in boiling water. Deprived of this covering, they are called *blanched almonds*. On exposure to the air they are apt to become rancid; but, if thoroughly dried and kept in well-closed glass vessels, they may be preserved unaltered for many years. Each of the two varieties requires a separate notice.

Sweet almonds are without smell when blanched, and have a sweet, very pleasant taste, which has rendered them a favorite article of diet in all countries where they are readily attainable. They are, however, generally considered difficult of digestion. The Pharmacopœia thus describes them. "Closely resembling the bitter almond (see *Amygdala Amara*), but having a bland, sweetish taste, free from rancidity. When triturated with water, it yields a milk-white emulsion, free from the odor of hydrocyanic acid." *U. S.* By the analysis of M. Boullay, it appears that they contain, in 100 parts, 5 parts of pellicle, 54 of fixed oil, 24 of albumen, 6 of uncrystallizable sugar, 3 of gum, 4 of fibrous matter, 3·5 of water, and 0·5 of acetic acid, comprising loss. The albumen is somewhat peculiar, and is called *emulsin*. It may be obtained separate by treating the emulsion of almonds with ether, allowing the mixture, after frequent agitation, to stand until a clear fluid separates at the bottom of the vessel, drawing this off by a siphon, adding alcohol to it so as to precipitate the emulsin, then washing the precipitate with fresh alcohol, and drying it under the receiver of an air-pump. In this state it is a white powder, inodorous and tasteless, soluble in water, and insoluble in ether and alcohol. Its solution has an acid reaction, and, if heated to 100° C. (212° F.), becomes opaque and milky, and gradually deposits a snow-white precipitate, amounting to about 10 per cent of the emulsin employed. (*A. J. P.*, xxi. 354.) Its distinguishing characteristic is that of producing certain changes, noticed previously, in amygdalin, which property it loses when its solution is boiled, though not by exposure in the solid state to a heat of 100° C. (212° F.). (*Ibid.*, 357.) It consists of nitrogen, carbon, hydrogen, and oxygen, with a minute proportion of sulphur, and is probably identical with the *synaptase* of Robiquet. Mr. L. Portes announced the discovery of *asparagin* in sweet almonds. (*N. R.*, January, 1877.) The fixed oil is described under the head of *Oleum Amygdalæ*, to which the reader is referred. Sweet almonds, when rubbed with water, form a milky emulsion, free from the odor of hydrocyanic acid, the insoluble matters being suspended by the agency of the albuminous, mucilaginous, and saccharine principles.

Medical Properties and Uses. *Sweet almonds* have no other influence on the system than that of a nutrient and demulcent. The emulsion formed by triturating them with water is a pleasant vehicle. From their nutritive properties, and the absence of starch in their composition, they are much used in the diet of *diabetics*, as originally recommended by Dr. Pavy. (*Guy's Hosp. Rep.*, 1862, p. 213.) *Bitter almonds* are more active, and might be employed with advantage in *pectoral* and other complaints to which hydrocyanic acid is applicable. In some persons almonds produce urticaria, in the smallest quantities. Largely taken, they have sometimes proved deleterious. Landerer mentions the case of a lady who was alarmingly affected by a bath made from the residue of bitter almonds after expression of the fixed oil (*A. J. P.*, xxviii.) Wöhler and Liebig propose as a substitute for cherry-laurel water, which owes its effects to the hydrocyanic acid it contains, but is objectionable from its unequal strength, an extemporaneous mixture, of seventeen grains of amygdalin, and one fluidounce of an emulsion made with two drachms of *sweet* almonds and a sufficient quantity of water. This mixture contains, according to the above-named chemists, one grain of anhydrous hydrocyanic acid, and is equivalent to two fluidounces of fresh cherry-laurel water. If found to answer in practice, it will have the advantage of certainty in relation to the dose; as amygdalin

* In 1861, Dr. Geo. B. Wood was informed, when at Valencia, that the thin, paper-shelled almonds were produced, not in the immediate neighborhood, but chiefly in the Balearic Islands, and the province of Alicante, whence they are sent to Valencia; and in a journey through the interior from Valencia to Alicante he noticed that the almond-tree was very abundant in the region back of the latter city, while there were comparatively few near the former.

may be kept any length of time unaltered. If the calculation of Wöhler and Liebig be correct as to the quantity of acid it contains, not more than a fluidrachm (3·75 C.c.) should be given as a commencing dose.

AMYL NITRIS. U.S., Br. Amyl Nitrite.

$C_5H_{11}NO_2$; 116·78. (Ā'MŸL NĪ'TRĬS.) $C_5H_{11}NO_2$; 117.

"A liquid containing about 80 per cent. of Amyl (principally Iso-amyl) Nitrite [$C_5H_{11}NO_2 = 116.78$], together with variable quantities of undetermined compounds. It should be kept in small, dark amber-colored and glass-stoppered vials, in a cool and dark place, remote from lights or fire." *U. S.* "A liquid produced by the interaction of amylic alcohol which has been distilled between 262° and 270° F. (127·7° to 132·2° C.) and nitrous acid. It consists chiefly of iso-amyl nitrite, $C_5H_{11}NO_2$, but contains also other nitrites of the homologous series." *Br.*

Amylium Nitrosum, Amylæther Nitrosus; Azotite d'Amyl, *Fr.*; Amyl Nitrite, *G.*; Amylo-nitrous Ether.

This substance, which was discovered by M. Balard in 1844, should not be confounded with *amyl nitrate*, $C_5H_{11}NO_3$, which is not used as a medicine.

Preparation. Amyl nitrite may be prepared by passing a stream of nitrous acid (hyponitric acid) gas through purified amylic alcohol at a temperature of 132° C. (269·6° F.), or by acting upon amylic alcohol with nitric acid, as originally suggested by Balard. The alcohol should always first be purified according to the method of Hirsch (*A. J. P.*, 1862, pp. 139, 328), by agitating with an equal bulk of strong solution of common salt, then distilling in a retort with a thermometer, collecting what comes over between 125° C. (257° F.) and 140° C. (284° F.), and redistilling this until it has a boiling point near 132° C. (269·6° F.). The purified alcohol should be mixed with about an equal bulk of nitric acid in a capacious glass retort, being gradually heated until it approaches boiling, when the fire is to be removed. As soon as a thermometer inserted into the tubulures rises above 100° C. (212° F.) the receiver is changed, because both ethyl-amylic ether and amyl nitrate at such temperatures come over freely and would contaminate the product. The distillate obtained below 100° C. (212° F.) is agitated with a solution of potassium carbonate, and the oily liquid which separates is very slowly heated in a clean retort to 96° C. (204·8° F.), then the receiver is changed and the distillate collected as before, until the thermometer reaches 100° C. (212° F.). That which comes over between the two temperatures is pure amyl nitrite. It is essential to this process that in every case the heating be very gradual. (*A. J. P.*, 1871, p. 148.) Allen states (*Commerc. Org. Anal.*, 2d ed., i. 159) that the use of nitric acid is certain to result in the formation of much valeric aldehyde and more or less amyl nitrate, and the boiling point of the former of these bodies precludes the possibility of subsequently separating it by fractioning the crude product. He therefore prefers the passing of nitrous acid gas into purified amyl alcohol. Prof. Maisch attempted to produce amyl nitrite by Redwood's process (*A. J. P.*, 1867, p. 330) for the production of nitrous ether, substituting amylic for ethylic alcohol. He found that the reactions occurred with such excessive violence as to render the preparation of the nitrite in this way impracticable. Subsequently, however, Mr. Alfred Tanner pointed out (*P. J. Tr.*, Nov. 1871, also *A. J. P.*, 1872, p. 21) that Prof. Maisch used a nearly anhydrous amylic alcohol, and that the reactions are equally violent with ethylic alcohol of similar strength. He finds no difficulty when the fused oil is diluted with water, and prefers the process, especially for the production of the drug upon a small scale. Having introduced the purified amylic alcohol into a tubulated retort containing copper wire, he adds one-tenth of its bulk of strong sulphuric acid, and then the same quantity of nitric acid, previously diluted with an equal bulk of water, and heats gently to 63° C. (145·4° F.). At this temperature the reaction commences, and goes on very manageably, until a bulk about equal to double the quantity of nitric acid collects in the receiver. The chemical movement now ceases, and the temperature, which has risen to near 100° C. (212° F.), begins to fall. More dilute nitric acid is added, and the process carried out as before. These additions are repeated until the amylic alcohol is exhausted, which is known by the appearance of red fumes in the retort. The whole product is washed with caustic soda, to remove hydrocyanic and other acids, and rectified over potassium carbonate, to get rid of moisture. The portion which distils over between 95° C. (203° F.) and 100° C. (212° F.) is medicinally pure amyl nitrite. John Williams (*Year-Book of Pharmacy*, 1885) recommends the method of passing nitrous acid, obtained by acting upon lump arsenous acid with nitric acid, sp. gr. 1·350, into purified amylic alcohol until the latter has

assumed a brownish-green color; the product is then washed and distilled fractionally; the distillate under 100° C. and 105° C. amounted to nearly 95 per cent. Mr. D. B. Dott (*P. J. Tr.*, Aug. 31, 1878) called attention to the difficulties in the way of fixing a standard boiling point for amyl nitrite, and Dr. W. H. Greene (*A. J. P.*, 1879, p. 65) shows that nitropentane (an isomer of amyl nitrite) is almost invariably a constituent of amyl nitrite, and he believes that commercial amyl nitrite is frequently put upon the market unrectified, specimens examined having boiling points varying from 70° C. (158° F.) to 180° C. (356° F.).

Prof. Dunstan and W. Lloyd Williams (*Pharm. Journ. and Trans.*, Dec. 22, 1888, p. 487) have shown that the supposed pure amyl nitrite is a mixture of α-amyl nitrite and β-amyl nitrite, arising from the fact that the amyl alcohol used is always a mixture of α-amyl alcohol and β-amyl alcohol in varying proportions. They find the α-amyl nitrite to be optically inactive and to boil at 97° C., while the β-amyl nitrite has dextro-rotatory power and boils at about 94° C. Much of the commercial amyl nitrite contains also iso-butyl nitrite, boiling at 67° C.*

Properties. "A clear, yellow or pale yellow liquid, of a peculiar, ethereal, fruity odor, and a pungent, aromatic taste. Specific gravity, 0·870–0·880 at 15° C. (59° F.). Almost insoluble in water; miscible, in all proportions, with alcohol or ether. In alcoholic solution it gradually decomposes with formation of ethyl nitrite and amylic alcohol. It is very volatile, even at a low temperature, and is inflammable, burning with a fawn-colored flame. At about 96°–99° C. (204·8°–210·2° F.), it boils, yielding an orange-colored vapor. If 1 C.c. of potassium hydrate normal volumetric solution and 10 C.c. of water be mixed with a drop of phenolphtalein test-solution, then 5 C.c. of Amyl Nitrite added, and the tube inverted a few times, the red tint of the alkaline layer should still be perceptible (limit of *free acid*). On shaking together equal volumes of Amyl Nitrite and potassium hydrate test-solution, the aqueous layer should not acquire a deeper tint than pale yellow (limit of *aldehyde*). Amyl Nitrite should remain transparent, or nearly so, when exposed to the temperature of melting ice (absence of *water*). If 0·26 Gm. of Amyl Nitrite, diluted with about 5 C.c. of alcohol, be introduced into a nitrometer, followed by 10 C.c. of potassium iodide test-solution, and afterwards by 10 C.c. of sulphuric acid normal volumetric solution, the volume of nitric oxide generated, measured at the ordinary in-door temperature (assumed to be at or near 25° C., or 77° F.), should be about 40 C.c. (each C.c. indicating about 2 per cent. of pure Amyl Nitrite)." *U. S.* "Almost insoluble in *water;* soluble in *alcohol* (90 per cent.) in all proportions. If it be added drop by drop to fused *potassium hydroxide*, potassium iso-valerianate will be formed. Specific gravity 0·870 to 0·880. Submitted to distillation, about 70 per cent. passes over between 194° and 212° F. (90° and 100° C.), the bulb of the thermometer not dipping below the surface of the residual fluid. A mixture of 5 volumes with sufficient *alcohol* (90 per cent.) to form 100 volumes affords a liquid of which a portion tested in a nitrometer as described under 'Spiritus Ætheris Nitrosi' should yield not less than 6 times its bulk of nitric oxide gas. On shaking with an equal volume of *solution of potassium hydroxide* the aqueous portion should have only a pale yellow color (limit of aldehyde). A small quantity in a test-tube placed in melting ice remains transparent (absence of water). It deteriorates unless kept in well-stoppered bottles." *Br.* According to Carl E. Smith (*A. J. P.*, 1898, p. 273), the official method of assay (Allen's) is not accurate, owing to the nitric oxide instantly changing to nitrogen tetroxide on contact with air, and this continuing to set free the iodine in the solution of hydriodic acid, thus registering too high a result. He proposes the use of a solution of potassium chlorate, nitric acid, silver nitrate, ferric ammonium sulphate, and potassium sulphocyanate.

Medical Properties and Uses. Owing to its excessive volatility and the ease with which it is absorbed, amyl nitrite acts with great quickness upon the organism. As early as 1859, Guthrie investigated, to some extent, its physiological action; but the attention of the profession was really first directed to the drug by the researches of Dr. Richardson, of London, in 1865. Since that time elaborate studies of its physiological action have been made by various investigators. Want of space forbids more than a summarizing of them in this book: for a full account the reader is referred to Dr. H. C. Wood's Treatise on Therapeutics. When inhaled in doses of from 5 to 10 drops, amyl nitrite produces in man violent flushing of the face, accompanied with a feeling as though the head would burst, and a very excessive action

* It is a question whether the physiological action of commercial amyl nitrite is really due to the amyl nitrite or to impurities, especially to the iso-butyl-nitrite, but the experiments of Brunton and Bokenham (*P. J. Tr.*, xix. 490) indicate that the commercial, impure nitrite is stronger than either pure α- or β-amyl nitrite. According to Bals and Broglio, the *tertiary amyl nitrite* ($C_5H_{11}NO_2$) differs from amyl nitrite in not giving rise to toxic symptoms, and in being slightly hypnotic.

of the heart. Along with these symptoms, after a larger quantity, there is a sense of suffocation, and more or less marked muscular weakness. As no case of serious poisoning from amyl nitrite has occurred in man, for a further knowledge of its action we are dependent upon studies made on the lower animals. In dogs, rabbits, cats, etc., it induces effects similar to those occurring in man, followed, after toxic doses, by violently hurried, panting respiration, progressive loss of muscular power and of reflex activity, and finally death from failure of respiration, sensation and consciousness being preserved to the last. Although the frequency of the pulse may be increased, the force of the circulation is always diminished. This decrease of the arterial pressure is in a great measure due to a dilatation of the capillaries. The vaso-motor palsy appears to be chiefly produced by a direct action upon the coats of the capillaries, but may in part be caused by an influence exerted upon the vaso-motor centres. The cause of the acceleration of the pulse has not been positively made out, but there is evidence for the belief that the rise is due to a depressing action upon the inhibitory cardiac nerves, and it is also probable that small quantities of the drug are primarily stimulant to the cardiac muscle.

The diminution of voluntary movements and of reflex action is chiefly owing to a powerful depressing influence exerted upon the spinal centres, although the drug does act to some extent upon both motor nerve and muscle, lowering their functional activity. Upon the perceptive and conscious portions of the nervous system amyl nitrite has almost no influence, so that, as already stated, both consciousness and sensation are preserved in poisoning by it almost to the close. After toxic doses the animal temperature falls in a remarkable degree. Very small doses produce in man a slight (½° F.) temporary increase of the bodily heat, probably caused by the vascular dilatation. The vapors of amyl nitrite outside of the body have a very extraordinary power of checking oxidation, and the results of numerous experiments seem to show that in the body the drug lessens decidedly the chemical interchanges. With the possible exception of the decrease of temperature, the general symptoms produced by the poison do not seem to be due to this lowered oxidation, but to a direct influence exerted upon the various tissues. Locally applied, amyl nitrite causes a progressive loss of power in every highly organized tissue; this may end in a total cessation of function, but, even after this, recovery is possible, provided the poison be withdrawn sufficiently early.

The chief indication for the employment of amyl nitrite is to relax *spasm*, either of the vaso-motor muscular fibres or of the voluntary or involuntary muscles. A disease, probably associated with vaso-motor spasm, but whose pathology is not established, in which experience has demonstrated the extreme value of amyl nitrite, is *angina pectoris*. Immediate and great relief is nearly always afforded, whether the heart-pain be or be not connected with *organic cardiac disease*. So far as experience goes, the cautious use of the remedy is safe, even when there is severe organic cardiac disease. In these cases it should always be administered by inhalation. Experience has also justified the use of the drug in many spasmodic diseases. In *asthma* the relief is often immediate; in *convulsions* occurring after labor the nitrite affords quiet, but its employment is dangerous on account of its tendency to produce uterine relaxation and consequent flooding. In *spasmodic dysmenorrhœa* good may be expected from its use; in *tetanus* it will frequently temporarily arrest the spasm and aid other remedies in obtaining recovery; in *strychnine poisoning*, in *hysterical convulsions*, indeed, in almost any convulsive disorder, much is to be expected from its employment. The convulsive stage of the ordinary *epileptic paroxysm* is so short that the nitrite is usually not available; when, however, there is a marked *epileptic stasis* and the patient passes from one convulsion to another, the drug may be used with benefit. In those cases in which there is an aura of sufficient length, the epileptic attacks may be arrested by the patient carrying in the pocket pearls of the nitrite or a tightly-corked homœopathic vial containing five or ten drops of the remedy, and, as soon as the aura commences, inhaling deeply.

Amyl nitrite is generally administered by inhalation, usually in doses of from three to five drops, although much larger quantities have been given without bad results. The rule is to commence with three drops on a handkerchief held close to the nose, and then gradually to increase *pro re nata*. The handkerchief should always be withdrawn so soon as the face flushes or the heart begins to become excited, as the effects always increase for some time, even if no more be inhaled. The best method, however, of administering the very volatile liquid is by the use of the glass pearls,—small flask-shaped vessels containing 2, 5, or 10 minims of the nitrite; these are crushed in a handkerchief or towel when wanted for inhalation, the very thin and friable glass causing no inconvenience. The drug may also be given by the mouth, in doses of three to five drops (0·18–0·3 C.c.) on sugar or dissolved in alcohol.

AMYLUM. U. S., Br. Starch.

(ĂM'Ŧ-LŬM.)

"The fecula of the seed of Zea Mays, Linné (nat. ord. Gramineæ)." *U. S.* "The starch procured from the grains of common wheat, Triticum sativum, Lam.; maize, Zea Mays, Linn.; and rice, Oryza sativa, Linn." *Br.*

Amylum Tritici; Corn Starch, Wheat Starch, *E.;* Fécule (Amidon) de Froment, de Blé, Amidon, *Fr.;* Stärkmehl, Stärke, Kraftmehl, Weizenstärke, *G.;* Amido, *It.;* Almidon, *Sp.*

Starch is a proximate vegetable principle contained in most plants, and especially abundant in the various grains, such as wheat, rye, barley, oats, rice, maize, etc.; in other seeds, as peas, beans, chestnuts, acorns, etc.; and in numerous rhizomes and tuberous roots, as those of the potato (*Solanum tuberosum*), the sweet potato (*Convolvulus batatas*), the arrow-root, etc. The starch is always in the form of grains, which are contained within the parenchymatous cells, and is procured by reducing the substances in which it exists to a state of minute division, agitating or washing them with cold water, straining or pouring off the liquid, and allowing it to stand till the fine fecula which it holds in suspension has subsided. This, when dried, is starch, more or less pure, according to the care taken in conducting the process. Electricity has been used to bleach starch and thus raise its commercial value. (*Drug. Circ.* 1893, 203.) In the U. S. P. of 1880 the official starch was that derived from wheat, but in the revision of 1890 corn starch was substituted. The starch of commerce is sometimes obtained from the potato. For a description of the differences, see page 172.

Starch is white, inodorous and tasteless, pulverulent, opaque, and, as found in commerce, is usually in columnar or irregular angular masses which are easily reduced to powder, and produces a peculiar sound when pressed between the fingers. Its specific gravity is 1.505 at 67° F. (*Payen.*) It is composed of minute microscopic granules, in starch from the same plant nearly uniform in size, more or less plainly striate, and having a distinct hilum. In the different species of plants the starch granules differ in their characteristic forms. When exposed to a moist air, it absorbs a considerable quantity of water, which may be driven off by a gentle heat. It is insoluble in alcohol, ether, and cold water, but unites with boiling water, which, on cooling, forms with it a soft semi-transparent paste, or a gelatinous opaline solution, according to the proportion of starch employed. The paste placed on folds of blotting-paper, renewed as they become wet, abandons its water, contracts, and assumes the appearance of horn. If the proportion of starch be very small, the solution, after slowly depositing a very minute quantity of insoluble matter, continues permanent, and upon being evaporated yields a semi-transparent mass, which is partially soluble in cold water. The starch has, therefore, been modified by the combined agency of water and heat; nor can it be restored to its original condition. Heating with glacial acetic acid to 100° C., or with glycerin to 190° C., will also make starch soluble. "Triturated with cold water it gives neither an acid nor an alkaline reaction with litmus-paper. When boiled with water, it yields a white jelly having a bluish tinge, which, when cool, acquires a deep blue color on the addition of iodine test-solution. When completely incinerated, starch should leave not more than 1 per cent. of ash." *U. S.* At a temperature of 160° C. (320° F.) for air-dried starch, and 200° C. (392° F.) for starch previously dried at 100° C., it is changed into *dextrin* (*British gum*), and at 200° C. (392° F.) to 215° C. (419° F.) forms a transparent fused mass, which consists exclusively of dextrin (*Payen*); at 220° C. (428° F.) to 230° C. (446° F.) it undergoes further change and yields yields chiefly *pyrodextrin*, a brown, tasteless, and odorless compound, readily soluble in water, insoluble in alcohol and ether. (Gelis, *Ann. Chim. Phys.*, (3) lii. 388.)

Composition and Nature. The formula of starch is generally taken as $C_6H_{10}O_5$, or a multiple of this. Musculus, in 1861, showed that by the action of dilute acids or of *diastase* starch is resolved into *dextrin*, $C_{12}H_{20}O_{10}$, and *dextrose*, $C_6H_{12}O_6$, so that its formula, in simplest terms, would be $(C_6H_{10}O_5)_3$. Recent determinations of its molecular weight by Brown and Morris make it as high as $5(C_{12}H_{20}O_{10})_{20}$. Iodine forms with starch, whether in its original state or in solution, a blue compound; and the tincture of iodine is the most delicate test of its presence. The color varies somewhat according to the proportions employed. When the two substances are about equal, the compound is of a beautiful indigo blue; if the iodine be in excess, it is blackish blue; if the starch, violet blue. A singular property of starch iodide is that its solution becomes colorless if heated to about 93·5° C. (200° F.), and afterwards recovers its blue color upon cooling. By boiling, the color is permanently lost, whilst Puchot states that certain nitrogenized organic bodies, as albumen, prevent the reaction of iodine on

starch or destroy it. (*N. R.*, Nov. 1876.) Alkalies unite with starch, forming soluble compounds, which are decomposed by acids, the starch being precipitated. It is thrown down from its solution by lime water and baryta water, forming insoluble compounds with these earths. The solution of lead subacetate precipitates it in combination with the oxide of the metal. Starch may be made to unite with tannin by boiling their solutions together; and a compound results, which, though retained by the water while hot, is deposited when it cools. By long boiling with diluted sulphuric, hydrochloric, or oxalic acid, it is converted into *dextrin** and glucose or grape sugar. A similar conversion into dextrin and glucose is effected by means of a principle called *diastase*, discovered by MM. Payen and Persoz in the seeds of barley, oats, and wheat, after germination. (See *Hordeum.*) Strong hydrochloric and nitric acids dissolve starch; and the latter, by the aid of heat, converts it into oxalic and malic acids. By the action of strong nitric, sulphuric, or crystallizable acetic acid, used with certain precautions, the starch is rendered soluble, and may be obtained in this state by separating the acid by means of alcohol. (*Chem. Gaz.*, Dec. 1, 1854, p. 450.) By the continued action of concentrated sulphuric acid it is decomposed. When it is dissolved in strong nitric acid, and precipitated by water, a white powder is thrown down, called *xyloidin*, $C_6H_9(NO_2)O_5$ (*Braconnot*), in which one atom of the hydrogen of the starch is replaced by one group, NO_2, furnished by the nitric acid. Mixed with hot water and exposed to a temperature of 27° C. (80° F.), it undergoes chemical changes, which result in the formation of several distinct principles, among which are sugar, a gummy substance (perhaps *dextrin*), and a soluble modification of starch. With yeast, starch undergoes the vinous fermentation, being, however, first converted into sugar. Mixed with cheese and chalk it is said to yield alcohol without the previous saccharine conversion. (Berthelot, *Journ. de Pharm.*, 3e sér., xxxii. 260.) All plants which contain chlorophyll have the power of using the chemical rays of sunlight in producing from inorganic compounds and elements a substance which is organic. There is first formed in the centre of the chlorophyll granule a minute speck, which is believed to be starch; this new starch granule is incapable of solution, but by conversion into sugar or dextrin is rendered soluble, and in this form is carried in the juices of the plant. One of two destinies there awaits it. It may be converted into the permanent compound cellulose which constitutes the woody tissue, or it may be reconverted to its original form and be deposited in some part of the plant. These stores of starch are usually accumulated for future growth, and are especially seen in plants which flower in the spring before the leaves are put forth, or which reproduce the species without seeding. When the potato is planted by the farmer, the starch is converted into a soluble form, passes into the growing "eye" or bud, and, as cellulose, forms the new shoot. Different opinions have been held as to the precise structure of the starch granules. The one first adopted is that they consist of a thin exterior coating, and of an interior substance; the former wholly insoluble, the latter soluble in water. The former constitutes, according to M. Payen, only 4 or 5 thousandths of the weight of starch. In relation to the interior portion there is not an exact coincidence of opinion. M. Guérin supposed that it consisted of two distinct substances, one soluble in cold water, the other soluble at first in boiling water, but becoming insoluble by evaporation. Thus, when one part of starch is boiled

* *Dextrin* is a substance resembling gum in appearance and properties, but differing from it in not affording mucic acid by the action of nitric acid. It is largely dissolved by water, hot or cold, and forms a mucilaginous solution, from which it is precipitated by alcohol. Large quantities of dextrin are now made both here and abroad and employed for various purposes in the arts, under the name of *artificial gum.* It is found in the market usually in the form of a yellowish or brilliant white powder, and in small masses or fragments resembling natural gum. According to M. Emil Thomas, it may be distinguished from gum arabic by the taste and smell of potato oil which it always possesses. It is made by the action either of acids or of diastase on starch, or by heating starch slightly moistened with nitric acid to a temperature of from 100° to 140° C. For particulars as to the manufacture, the reader is referred to a paper by M. Thomas, republished in *A. J. P.* (vol. xix. p. 284). Researches of Nägili and Musculus seem to show that the change of starch into dextrin takes place in several phases, and they name the several products *amylodextrin, erythrodextrin, achrodextrin α and β.* For a fuller account of these products, see Husemann, *Pflanzenstoffe*, 2d ed., 1882.

Dextrin, according to Payen, is converted into glucose, through the action of diastase; but the glucose impedes the action unless removed; as, however, during the alcoholic fermentation the glucose is consumed, no obstacle prevents the influence of diastase. Hence dextrin by conversion into sugar may contribute to the alcoholic product. (*Journ. de Pharm.*, 4e sér., i. 363.)

Adulteration and purification of dextrin.—Commercial dextrin is said to be occasionally very impure. Several parcels analyzed by Dr. H. Hayes were found to contain an average of about 45 per cent. of impurities, consisting mainly of insoluble matter with sugar and water. He recommends, as the best method of purifying it, to dissolve 10 parts of the impure dextrin, with agitation, in 18 parts of distilled water, in a cylindrical vessel; to decant the solution when it has become clear on standing, and mix it with 1·5 or 2 per cent. of alcohol of 95 per cent. The liquid is then decanted from the doughy precipitate formed, which is dissolved in a little distilled water, and the solution spread on glass or porcelain plates to dry, in a warm place. (*A. J. P.*, 1870, p. 327.)

for fifteen minutes in one hundred parts of water, and the liquid is allowed to stand, a small portion, consisting of the broken teguments, is gradually deposited. If the solution be now filtered and evaporated, another portion is deposited which cannot afterwards be dissolved. When wholly deprived of this portion, and evaporated to dryness, the solution yields the part soluble in cold water. According to MM. Payen and Persoz, the interior portion of the globules consists only of a single substance, which is converted into the two just mentioned by the agency of water; and Thénard is inclined to the same opinion. An appropriate name for the interior soluble portion of starch is *amidin*, which has been adopted by some chemists. Starch, in its perfect state, is not affected by cold water, because the exterior insoluble teguments prevent the access of the liquid to the interior portion; but when the pellicle is broken by heat, or by mechanical means, the fluid is admitted, and the starch partially dissolved.

Another view of the structure of the starch granule, founded on microscopic observation, was advanced by Schleiden. According to this observer, it consists of concentric layers, all of which have the same chemical composition; but the outer layers, having been first formed, have more cohesion than the inner, and are consequently of more difficult solubility. The rings observed upon the surface of the granules, in some varieties, are merely the edges of these layers; and the point or hilum about which the rings are concentrically placed is a minute hole, through which probably the substance of the interior layers was introduced. (*Pharm. Centralb.*, 1844, p. 401.)

Mr. J. J. Field thinks he has demonstrated that the granule consists, as at first supposed, of an interior matter surrounded by a distinct membranous envelope. Having saturated some canna starch with glycerin, and then added a little water, an endosmose of the thinner outer liquid took place into the granules, distending them so as to rupture their investing membrane, which was distinctly visible, under the microscope, in longitudinal wrinkles. The concentric rings he thinks nothing more than folds of the membrane, produced probably by the contraction of the granules. (*P. J. Tr.*, xiv. 253.)

The tegumentary portion of starch, for which the name of *amylin* has been proposed, is, when entirely freed from the interior soluble matter, wholly insoluble in water even by prolonged boiling, insoluble in alcohol, and said to suffer no change by the action of diastase. The acids, however, act upon it as they do upon starch. It is thought to approach nearer in properties to lignin than to any other principle. Musculus (*Comptes-Rendus; Journal Franklin Institute*, June, 1879) believes that starch may exist in either an amorphous or a crystallizable form. In its amorphous state it is soluble in water, capable of being acted on by diastase, soluble in diluted mineral acids, but easily rendered insoluble by undergoing modifications. In its crystalline condition it can be obtained in isolated crystals, which can be readily dissolved in cold water, but when these crystals are united they become less soluble, and then it largely has the properties of the amorphous variety. Sulkowsky (*Ber. d. Chem. Ges.*, xiii. 1395) states that starch may be rendered soluble by heating with glycerin to 190° C. (374° F.), and pouring whilst hot into water, filtering and adding alcohol to the filtrate, which causes precipitation of the soluble starch.

The view that is held in most esteem at the present time is that the granules of starch consist of two substances, *granulose* and *amylo-cellulose*. The latter occurs in largest proportion in the outer layers of the granule, and probably so envelops and protects the granule as to prevent the action of cold water upon it, the granulose or inner portion being slightly soluble. When the granules are ruptured by being triturated with sand, water acts upon them, and the liquid will yield a blue color with iodine. The insoluble amylo-cellulose may be obtained pure by treating starch paste with extract of malt; it gives then a brownish-yellow color (not a blue) with iodine. Granulose is acted on by ptyalin (the ferment from saliva), pepsin, organic acids, diluted hydrochloric or sulphuric acid, whilst amylo-cellulose is unaffected. The solid starch granules become blue when touched by tincture of iodine, because the liquid penetrates through the fissures of the amylo-cellulose to the granulose.

Varieties. Starch, as obtained from different substances, is somewhat different in its characters. *Wheat starch*, when examined with a microscope, is found to consist of granules varying from about $\frac{1}{1000}$ of an inch in diameter to a mere point, the smaller being spheroidal, the larger rounded and flattened, with the hilum in the centre of the flattened surface, and surrounded by concentric rings, which often extend to the edge. The granules are mixed with loose integuments, resulting from the process of grinding. This variety of starch has a certain degree of hardness and adhesiveness, owing, according to Guibourt, to the escape of a portion of the interior substance of the broken granules, which attracts some moisture from the air, and,

thus becoming glutinous, acts as a bond between those which remain unbroken. Another opinion attributes this peculiar consistence to the retention of a portion of the gluten of the wheat flour, which causes the granules to cohere. Under the name of *corn starch*, a variety of fecula obtained from the meal of maize or Indian corn is much used for nutritive purposes in the United States. It is now the official starch. The granules of maize starch are very small, with a diameter not exceeding, according to Payen, one-sixth of that of the potato, and little more than one-half of that of the wheat granules. They have a very distinct hilum but no evident concentric striæ. *Rice starch* has extremely minute granules, nearly uniform in size, polygonal, without evident hilum or striæ. *Potato starch* is employed in various forms, being prepared so as to imitate more costly amylaceous substances, such as arrow-root and sago. In its ordinary state it is more pulverulent than is wheat starch, has a somewhat glistening appearance, and may be distinguished, with the aid of the microscope, by the size of its granules, which are larger than those of any other known fecula except canna, or *tous les mois.** They are exceedingly diversified in size and shape, though their regular form is thought to be ovate. The characters of other kinds of fecula will be given under the heads of the several official substances of which they constitute the whole or a part. According to Chevallier, starch is sometimes adulterated with calcium carbonate and calcium sulphate; and the fraud is also practised of saturating it with moisture, of which it will absorb 12 per cent. without any obvious change.

Medical Properties, etc. Starch is nutritive and demulcent, but in its ordinary form is seldom administered internally. Powdered and dusted upon the skin, it is sometimes used to absorb irritating secretions and prevent excoriation. Dissolved in hot water and allowed to cool, it is often employed in enemata, either as a vehicle, or as a demulcent application in irritated states of the rectum. It may be used as an antidote to iodine.

ANETHI FRUCTUS. Br. Dill Fruit.

(Ạ-NĒ'THĪ FRŬC'TŬS.)

"The dried fruit of Peucedanum graveolens, Benth. and Hook." *Br.*

Aneth, Fenouil puant, *Fr.;* Dill, *G.*

Gen. Ch. Fruit nearly ovate, compressed, striated. *Petals* involuted, entire. *Willd.*

Anethum graveolens. Willd. *Sp. Plant.* i. 1469; Woodv. *Med. Bot.* p. 125, t. 48. Dill is an annual plant, three or four feet high, with a long spindle-shaped root; an erect, striated, jointed branching stem; and bipinnate or tripinnate, glaucous leaves, which stand on sheathing footstalks and have linear and pointed leaflets. The flowers are yellow, and in large, flat, terminal umbels, destitute of involucre. The plant is a native of Spain, Portugal, and the south of France, and is found growing wild in various parts of Africa and Asia. It is cultivated in all the countries of Europe, and has been introduced into our gardens. The seeds, as the fruit is commonly called, are the only part used. They are usually rather more than a line in length, and less than a line in breadth, of an oval shape, thin, concave on one side, convex and striated on the other, of a brown color, and surrounded by a yellowish membranous expansion. The dorsally compressed mericarps are usually separate and freed from the pedicel; each of them is broadly oval, about one-sixth of an inch long, flat, and furnished with three sharply keeled dorsal ridges, besides two marginal thin membranous projections or wings.

* Canna (*Amylum Cannæ; Tous les Mois, Amidon de Canne, Fécule de Tolomane,* Fr.; *Cannastärke,* G.). It is somewhat uncertain from what species of Canna the fecula is derived, though it is generally believed to be *C. edulis*. The tubers of *Canna achiras* (Gillies), growing in Central and South America, are said to be used as food in Peru and Chili (Lindley, *Med. and Econom. Bot.*, p. 50); and a root or rhizome closely resembling turmeric, and used by the native Africans at Sierra Leone for dyeing yellow, was found by Dr. Wm. F. Daniell to be the product of a species of Canna, believed to be the *C. speciosa* of Roscoe. (*P. J. Tr.*, Nov. 1859, p. 258.)

Canna edulis is a tuberous plant, with erect, smooth, purplish stems, from four to six feet high, and invested with sheathing leaves, which are ovate-oblong, tapering towards each end, smooth, and of a deep glaucous green, with purplish edges. The flowers are few, and in compact racemes, of a red and yellow color. The plant is a native of the West Indies, and is cultivated in the islands of St. Kitts and Trinidad, and perhaps others. The tubers are first rasped, by means of a machine, into a pulp, from which the starch is extracted in the usual manner, by washing and straining, and, after the washings have been allowed to stand, so as to deposit the fecula, decanting the clear liquid. (Pereira.) Canna starch is in the form of a light, beautifully white powder, of a shining appearance, very unlike the ordinary forms of fecula. Its granules are said to be larger than those of any other variety of starch in use, being from the 300th to the 200th of an inch in length. Under the microscope they appear ovate or oblong, with numerous regular unequally distant rings; and the circular hilum, which is sometimes double, is usually situated at the smaller extremity. (Pereira.) This fecula has the ordinary chemical properties of starch, and forms, when prepared with boiling water, a nutritious and wholesome food for infants and invalids. It may be prepared in the same manner as *arrow-root*, and is said to form even a stiffer jelly with boiling water. (See *Maranta.*)

The vittæ, or oil-tubes, are six in number, two upon the face and one in each furrow between the ridges. The odor is strong and aromatic, but less agreeable than that of fennel seed; the taste, moderately warm and pungent. These properties depend on a volatile oil. (See *Oleum Anethi.*) The bruised seeds impart their virtues to alcohol and to boiling water.

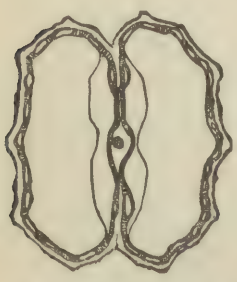
Medical Properties. Dill seeds have the properties common to the aromatics, but are very seldom used in this country. They may be given in powder or infusion. The dose of the fruit is from fifteen grains to a drachm (1–3·9 Gm.), of the oil three or four drops (0·18–0·24 C.c.).

ANISUM. U. S. (Br.) Anise.

(Ą-NĪ'SŬM.)

"The fruit of Pimpinella Anisum, Linné (nat. ord. Umbelliferæ)." *U. S.* "The dried ripe fruit of Pimpinella Anisum. Linn." *Br.*

Anisi Fructus, *Br.;* Fructus (Semen) Anisi, s. Anisi vulgaris; Aniseed, *E.;* Anis, Anis vert, Graines d'Anis, *Fr.;* Anissame, Anis, *G.;* Semi d'Aniso, *It.;* Simiente de Anis, *Sp.;* Anison, *Ar.*



Gen. Ch. Fruit ovate-oblong. *Petals* inferior. *Stigma* nearly globular. *Willd.*

Pimpinella anisum. Willd. *Sp. Plant.* i. 1473; *B. and T.* 122. This is an annual plant, about a foot in height, with an erect, smooth, and branching stem. The leaves are petiolate, the lower roundish-cordate, lobed, incised-serrate, the middle pinnate-lobed with cuneate or lanceolate lobes, the upper trifid, undivided, linear. The flowers are white, and in terminal compound umbels, destitute of involucres.

The anise plant is a native of Egypt and the Levant, but has been introduced into the south of Europe and is cultivated in various parts of that continent. It is also cultivated occasionally in the gardens of this country. The fruit is abundantly produced in Malta and Spain; in Romagna, in Italy, whence it is largely exported through Leghorn; and in Central and Southern Russia. The Spanish is smaller than the German or French, and is usually preferred; the Russian fruit is very short. It is said also to be extensively cultivated in India and South America, although we are not aware that the product ever comes into American commerce.

It is one of the oldest aromatics, having been spoken of by Theophrastus and cultivated in the imperial German farms of Charlemagne. In 1305 Edward I. granted a patent giving the right to levy tolls upon it at the Bridge of London for the purpose of repairing the bridge.

Anise seeds (botanically, fruit) are about a line in length, oval, striated, somewhat downy, attached to their footstalks, and of a light greenish-brown color, with a shade of yellow. "About 4 or 5 Mm. long, ovate, compressed at the sides, grayish, finely hairy, and consisting of two mericarps, each with a flat face, and five light brownish, filiform ridges, and about fifteen thin oil-tubes, which can be seen in a transverse section by the microscope." *U. S.* Their odor is fragrant, and increased by friction; their taste, warm, sweet, and aromatic. These properties, which depend upon a peculiar volatile oil, are imparted sparingly to boiling water, freely to alcohol. The volatile oil exists in the envelope of the seeds, and is obtained separate by distillation. (See *Oleum Anisi.*) Their internal substance contains a bland fixed oil. By expression, a greenish oil is obtained, which is a mixture of the two. The seeds are sometimes adulterated with small fragments of argillaceous earth, which resembles them in color; and their aromatic qualities are occasionally impaired by a slight fermentation, which they are apt to undergo in the mass, when collected before maturity. When examined by the microscope, anise is seen to contain a very great but variable number of small oil-tubes, which are well represented in the accompanying figure,—from fifteen to thirty to each mericarp. The epidermis is supplied with short, simple hairs, easily detached in making a section, and not represented in the cut.

A case of poisoning is on record from the accidental admixture of the fruits of *Conium maculatum*, which bear some resemblance to those of anise, but may be distinguished by their crenate or notched ridges and the absence of oil-tubes; by their mericarps being smooth, grooved upon the face, and having crenate or notched ridges with wrinkles between them; and especially by the absence of oil-tubes. The conium fruits are, moreover, broader in proportion to their length, and are generally separated into half fruits (or single mericarps), while those of anise are whole (double mericarps).

Star aniseed, the *Cardamomum Siberiense* or *Annis de Sibérie* of the seventeenth century and the *badiane* of the French writers, is the product of the *Illicium anisatum*, and is fully described under the heading *Illicium*. They contain about 4 per cent. of a volatile oil very

closely resembling that of anise. There are no known chemical differences between these oils, although dealers distinguish them by their smell and taste.

Dr. Ruschenberger, U.S.N., has shown that oil of anise has a remarkable power of deodorizing potassium sulphide; a drop of the oil having entirely deprived of offensive odor a drachm of lard with which five grains of the sulphide had been incorporated. (*Am. Journ. of Med. Sci.*, N. S., xlviii. 419.)

Medical Properties and Uses. Anise is a grateful aromatic carminative, and is supposed to have the property of increasing the secretion of milk. It has been in use from the earliest times. In Europe it is much employed in flatulent *colic*, and as a corrigent of griping or unpleasant medicines; but in this country fennel seed is preferred. Anise may be given bruised, or in powder, in the dose of twenty or thirty grains (1·3–1·95 Gm.) or more. The infusion is less efficient. The volatile oil may be substituted for the seeds in substance. Much use is made of this aromatic for imparting flavors to liquors.

ANTHEMIS. U. S. (Br.) Anthemis. [Chamomile.]

(ĂN'THĘ-MĬS.)

"The flower-heads of Anthemis nobilis, Linné (nat. ord. Compositæ), collected from cultivated plants." *U. S.* "The dried expanded flower-heads of Anthemis nobilis, Linn., collected from cultivated plants." *Br.*

Anthemidis Flores, *Br.;* Flores Chamomillæ Romanæ, *P. G.:* Roman or English Chamomile, *E.;* Camomille Romaine, *Fr.;* Römische Kamille, *G.;* Camomilla Romana, *It.;* Manzanilla Romana, *Sp.;* Chamomile Flowers.

Gen. Ch. Receptacle chaffy. *Seed-down* none or a membranaceous margin. *Calyx* hemispherical, nearly equal. *Florets of the ray* more than five. *Willd.*

Several species of Anthemis have been employed in medicine. *A. nobilis*, which is the subject of the present article, is by far the most important. *A. cotula*, or *mayweed*, was formerly recognized by the U. S. Pharmacopœia. *A. pyrethrum*, which affords the pellitory root, is among the official plants. (See *Pyrethrum.*) *A. arvensis*, a native of this country and of Europe, bears flowers which have an acrid bitter taste and possess medical properties analogous though much inferior to those of common chamomile. They may be distinguished by their want of smell. *A. tinctoria* is occasionally employed as a tonic and vermifuge in Europe. *Matricaria suaveolens* is said to yield the chamomile of the Indian bazaars.

Anthemis nobilis. Willd. *Sp. Plant.* iii. 2180; *B. and T.* 154. This is an herbaceous plant with a perennial root. The stems are from six inches to a foot long, round, slender, downy, trailing, and divided into branches, which turn upward at their extremities. The leaves are bipinnate, the leaflets small, threadlike, somewhat pubescent, acute, and generally divided into three segments. The flowers are solitary, with a yellow convex disk, and white rays. The calyx is common to all the florets, of a hemispherical form, and composed of several small imbricated hairy scales. The receptacle is convex, prominent, and furnished with rigid bristle-like paleæ. The florets of the ray are numerous, narrow, and terminated with three small teeth. The whole herb has a peculiar fragrant odor, and a bitter aromatic taste.

This plant is a native of Europe, and grows wild in all the temperate parts of that continent. It is also largely cultivated for medicinal purposes.* In France, Germany, and Italy, it is generally known by the name of *Roman chamomile.* By cultivation the yellow disk florets are often converted into the white ray florets. Thus altered, the flowers are said to be *double*, while those which remain unchanged are called *single;* but, as the conversion may be more or less complete, it generally happens that with each of the varieties there are intermingled some flowers of the other kind, or in different stages of the change. The double flowers are generally preferred; though, as the sensible properties are found in the greatest degree in the disk, the single are the most powerful. It is rather, however, in aromatic flavor than in bitterness that the radical florets are surpassed by those of the disk. If not well and quickly dried, the flowers lose their beautiful white color, and are less efficient. The flowers which are largest,

* Mr. Jacob Bell, of Mitcham, in Surrey, England, stated that the plant is usually propagated by dividing the root, though the seeds are employed when it is desired to introduce new varieties. Each root will serve as the source of thirty or forty plants. They are set in rows a yard apart, at intervals of about eighteen inches. The proper period for planting is in March; and the flowers are in perfection in July, but continue to appear throughout the season. Extremely wet or extremely dry weather is injurious to the crop. It is more productive in a rather heavy loam than either in light sandy soil or in stiff clay. It requires little manure, but attention to weeding is necessary. Over-manuring increases the leaves at the expense of the flowers. When gathered, the flowers are dried upon canvas trays in a drying-room, artificially warmed, where they remain about a day. The crop varies from three to ten hundred-weight per acre. The single flowers are more productive than the double by weight; but, as they command a less price, the value of the crop is about the same. (*P. J. T.*, x. 118.)

most double, and whitest should be preferred. They are thus described officially. "Heads subglobular, about 2 Cm. broad, consisting of an imbricated involucre, and numerous white, strap-shaped, three-toothed florets, and few or no yellow tubular disk florets, inserted upon a chaffy, conical, solid receptacle. It has a strong, agreeable odor, and an aromatic, bitter taste." *U. S.* The seeds yield by expression a fixed oil, which is said to be applied in Europe to various economical uses.

Though not a native of America, chamomile grows wild in some parts of this country, and is occasionally cultivated in our gardens for family use, the whole herb being employed. The medicine, as found in commerce, consists chiefly of the double flowers, and is imported from Germany and England. From the former country the flowers of *Matricaria chamomilla* are also occasionally imported, under the name of chamomile. (See *Matricaria.*) In France, the flowers of two other plants are sold in commerce indiscriminately with those of *Anthemis nobilis*,—viz., those of *Pyrethrum parthenium* (the *Chrysanthemum parthenium* of Persoon), or *feverfew*, and those of *Anthemis parthenoides*, De Cand., or the *Matricaria parthenoides*, Desf. (*Journ. de Pharm.*, Mai, 1859, p. 347.) For the peculiar character by which these two flowers may be distinguished from the chamomile, see *Pyrethrum parthenium* in PART II.

Properties. Chamomile flowers, as usually found in commerce, are large, almost spherical, of a dull white color, a fragrant odor, and a warmish, bitter, aromatic taste. When fresh, their smell is much stronger, and was fancied by the ancients to resemble that of the apple. Hence the name *chamæmelum* (χαμαί, on the ground, and μῆλον, an apple); and it is somewhat singular that the Spanish name *manzanilla* (a little apple) has a similar derivation. The flowers impart their odor and taste to water and alcohol, the former of which, at the boiling temperature, extracts only one-fourth of their weight. The investigations of several chemists performed in 1878–1879, in Fittig's laboratory at Strassburg, have shown the oil of chamomile to contain the following constituents:—a fraction distilling at 147°–148° C. (296°–298° F.) consisting of *isobutylic ethers* and hydrocarbons; *isobutyl angelicate* at 177° C. (350·5° F.); *isoamyl angelicate* at 200°–201° C. (392°–394° F.); *isoamyl tiglinate* at 204°–205° C. (399°–401° F.) (both of these compound ethers answering to the formula $C_5H_{11}.C_5H_7O_2$). In the residual portion, hexylic alcohol, $C_6H_{13}OH$, and an alcohol of the formula $C_{10}H_{16}O$ are met with, both probably occurring in the form of compound ethers. By decomposing the angelicates and the tiglinate above mentioned with potash, *angelic acid*, $C_5H_8O_2$, and *tiglinic acid* (or *methyl-crotonic*) isomeric with the former are obtained to the extent of about 30 or more per cent. of the crude oil. In the oil examined by Fittig, angelic acid prevailed; from another specimen E. Schmitt (1879) obtained but very little of it, tiglinic acid prevailing. Umney states that pure oil of chamomile has the sp. gr. 0·905 to 0·912 at 15° C. (*P. J. Tr.*, 1895, p. 949). For an examination of the oil from *Anthemis cotula*, which closely resembles that from *A. nobilis*, see *A. J. P.*, 1885, pp. 376, 381. E. Amerman (*A. J. P.*, 1889, p. 69) obtained a wax which was nearly white, bitter, and crystalline, melting at about 130° C., and a crystalline substance distinctly acid and of a glucosidal nature. There was no evidence of the presence of an alkaloid. Flückiger performed some experiments in order to isolate the *bitter principle*, but did not succeed in obtaining it in a satisfactory state of purity; it formed a brown extract, apparently a glucoside. He also confirms the absence of alkaloid.

Medical Properties and Uses. Chamomile is a mild tonic, in small doses acceptable and corroborant to the stomach, in large doses capable of acting as an emetic. In cold infusion it is often advantageously used in cases of *enfeebled digestion*, whether occurring as an original affection or consequent upon some acute disease. It is especially applicable to that condition of *general debility*, with languid appetite, which often attends convalescence from idiopathic fevers. As a febrifuge it formerly enjoyed much reputation, and was employed in *intermittents* and *remittents;* but we have remedies so much more efficient that it is now seldom used in this capacity. The tepid infusion is very often given to promote the operation of emetics, or to assist the stomach in relieving itself when oppressed by its contents. The flowers are sometimes applied externally in the form of fomentation, in cases of irritation or inflammation of the abdominal viscera, and as a gentle incitant in flabby, ill-conditioned *ulcers*. The dose of the powder as a tonic is from half a drachm to a drachm (1·95–3·9 Gm.) three or four times a day, or more frequently. The infusion is usually preferred. The decoction and extract cannot exert the full influence of the medicine, as the volatile oil is driven off.

ANTIMONIUM. Antimony.

Sb; 120. (ĂN-TĮ-MŌ′NĮ-ŭM.) **Sb; 120.**

Stibium, *Lat.;* Antimoine, *Fr.;* Antimon, Spiessglanz Metall, *G.;* Antimonia, *Sp., It.*

Metallic antimony, sometimes called *regulus of antimony*, is not official in the British or United States Pharmacopœias; but, as it enters into the composition of a number of important pharmaceutical preparations, we have thought it proper to notice it under a distinct head.

Antimony exists in nature—1, uncombined; 2, as an oxide; 3, as antimonous sulphide (tersulphide), and 4, as an oxysulphide. It is found principally in France and Germany, but has been discovered also in the provinces of New Brunswick and Ontario, Canada, the latter locality yielding a large portion of that consumed in the United States.

Extraction. All the antimony of commerce is extracted from the native sulphide. The ore is first separated from its gangue by fusion. It is then reduced to powder, and placed on the floor of a reverberatory furnace, where it is subjected to a gentle heat, being constantly stirred with an iron rake. This process of roasting is known to be completed when the matter is brought to the state of a dull grayish-white powder, called *antimony ash*. By this treatment the antimony is partly teroxidized, and partly converted into antimonious acid; while nearly all the sulphur is dissipated in the form of sulphurous acid gas; a portion of tersulphide, however, remains undecomposed. The matter is then mixed with charcoal impregnated with a concentrated solution of sodium carbonate, and the mixture heated in crucibles, in a melting-furnace. The charcoal reduces the antimony teroxide, while the alkali unites with the undecomposed tersulphide, and forms melted scoriæ, which cover the reduced metal and diminish its loss from volatilization. Antimony is more generally obtained by the reduction of the native iron sulphide. The reduction of the antimony sulphide by iron takes place at a red heat, but as iron sulphide needs a higher temperature for its fusion, and its specific gravity is not much less than that of the metallic antimony, the mass must be heated to a white heat to effect a perfect separation, and this occasions a loss of the antimony. In order to avoid this, sodium sulphide is added in practice, which unites with the iron sulphide to form a more fusible and lighter slag of double sodium and iron sulphide. To 100 parts of antimony sulphide are taken 42 parts of iron, 10 parts of anhydrous sodium sulphate, and 2½ to 3½ parts of carbon.

The purest commercial antimony is not entirely free from foreign metals, chiefly iron, lead, and arsenic. M. Lefort purifies it for the purposes of pharmacy by gradually adding twenty-five parts of the metal, in fine powder, to fifty parts of nitric acid, by the action of which the antimony is precipitated as antimonious acid, while the foreign metals remain in solution. The precipitate is then thoroughly washed with water containing a hundredth part of nitric acid, drained completely, mixed with three or four parts of powdered sugar, and reduced to the metallic state by being heated to redness in a Hessian crucible. (*Journ. de Pharm.*, Août, 1855.) Antimony is imported into the United States from France, packed in casks. It is also shipped from Trieste, from Holland, and occasionally from Cadiz. The Spanish antimony is generally in the form of pigs; the French, in circular cakes about ten inches in diameter, flat on one side and convex on the other; the English, in cones. Both native antimony and stibnite, or antimonous sulphide, are also brought from Southham, Canada. The production of metallic antimony in the United States in 1896 was 1,226,000 lbs., valued at $84,717, and in 1897, 1,500,000 lbs., valued at $107,250. In this latter year the ore used was about two-thirds American ore and the remainder Canadian ore. The importations of ore and regulus (or metal) during the same years were 4,087,425 lbs. and 4,464,608 lbs. respectively.

Properties, etc. The time of the discovery of antimony is not known; but Basil Valentine was the first to describe the method of obtaining it, in his work entitled *Currus Triumphalis Antimonii*, published towards the end of the fifteenth century. It is a brittle, brilliant metal, ordinarily of a lamellated texture, of a silver-white color when pure, but bluish white as it occurs in commerce. Its atomic weight is 120 (or, according to some authorities, 122), symbol Sb, sp. gr. 6·7, and fusing point 425° C. (797° F.), or about a red heat. On cooling, after fusion, antimony assumes an appearance on the surface bearing some resemblance to a fern leaf. When strongly heated, it burns with the emission of white vapors, consisting of teroxide, formerly called *argentine flowers of antimony*. A small portion being fused and then thrown upon a flat surface divides into numerous globules, which burn rapidly as they move along. It forms three combinations with oxygen, *antimony trioxide* (antimonous oxide), Sb_2O_3, *antimony tetroxide*, Sb_2O_4 (by some considered to be an antimonate of the tetroxide of

antimony, Sb_4O_8), and *antimony pentoxide* (antimonic oxide), Sb_2O_5. The first of these unites with water to form antimonous acid, the salts of which are called *antimonites*, the third unites with water to form antimonic acid, the salts of which are called *antimonates*. The trioxide will be noticed under the head of *Antimonii Oxidum*. The tetroxide is a white powder, yellowish when hot, and difficultly soluble in acids. It forms when either of the other two oxides is strongly heated in air. *Antimony ash*, described above, is also an impure tetroxide. *Antimonic acid* is a lemon-colored powder, which may be prepared by oxidizing the metal by digestion in nitric acid, and then driving off the excess of the acid by a heat not exceeding 315·5° C. (600° F.). When exposed to a red heat, it parts with oxygen, and is converted into the *antimony tetroxide* just described. This, though medicinally inert, frequently forms a large proportion of the preparation called antimonial powder. (See *Pulvis Antimonialis*.)

The antimonial preparations are active in proportion to their solubility in the gastric juice. According to Mialhe, those antimonials which contain the hydrated teroxide, or are easily converted into it, are most active. Hence metallic antimony in fine powder, and tartar emetic, act with energy. The teroxide is much more active when prepared in the moist than in the dry way. According to Sérullas, all the antimonial preparations except tartar emetic and butter of antimony (or terchloride) contain a minute proportion of arsenic. Tartar emetic is an exception, because it separates entirely, in the act of crystallizing, from any minute portion of arsenic in the materials from which it is prepared, the poisonous metal being left behind in the mother-water of the process.

ANTIMONII ET POTASSII TARTRAS. U. S. (Br.) Antimony and Potassium Tartrate. [Tartar Emetic; Tartarated Antimony.]

(ĂN-TĮ-MŌ'NĮ-Ī ĔT PŌ-TĂS'SĮ-Ī TĂR'TRĂS.)

$2KSbOC_4H_4O_6.H_2O$; 662·42. $2KSbOC_4H_4O_6.H_2O$; 664.

"Tartarated Antimony, $[K(SbO)C_4H_4O_6]_2H_2O$, is prepared by setting aside a mixture of antimonious oxide and acid potassium tartrate, made into a paste with a little water, until combination has taken place, and then purifying by crystallization from water." *Br.*

Antimonium Tartaratum, *Br.;* Antimonium Tartarizatum, Tartarized Antimony, Tartrated Antimony; Potassio-Tartrate of Antimony, Antimonii Potassio-Tartras, Tartarus Stibiatus, *P. G.;* Tartarus Emeticus, Stibio-Kali Tartaricum; Tartrate d'Antimoine et de Potasse, Emétique, Tartre stibié, *Fr.;* Brechweinstein, *G.*

A process for Tartar Emetic not being given in the U. S. Pharmacopœia, that of 1870 is inserted below.* This compound is a normal tartrate. Tartaric acid is dibasic. In acid potassium tartrate (cream of tartar) one of the two hydrogen atoms is replaced by potassium, while the other is unreplaced; in neutral potassium tartrate (soluble tartar) both are replaced by potassium; in tartar emetic one is replaced by potassium, while the other is replaced by the group (SbO) antimonyl, which is a univalent group, exactly replacing one hydrogen atom.

In the preparation of tartar emetic the cream of tartar should not be in excess; as in that case it is apt to crystallize, upon cooling, with the tartar emetic. To avoid such a result it is better to have a slight excess of antimonial oxide. No rule is applicable to the determination of the proper proportion of water, except that it should be sufficient to dissolve the tartar emetic formed. The hot filtration, directed in the U. S. Pharmacopœia of 1870, may be conveniently performed by a jacketed funnel filled with hot water. In all cases the salt should be obtained in well-defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.†

It is not easy to decide as to the relative eligibility of the different forms of antimonial oxide used for preparing tartar emetic. The preference, however, was given to the oxychloride (*powder of Algaroth*) by Berzelius; and M. Henry, an eminent pharmaceutist of Paris, after a careful comparison of the different processes, declared also in its favor; his process will be found in detail in the U. S. D., 17th ed., p. 175.

* "Take of Oxide of Antimony, in very fine powder, *two troyounces;* Bitartrate of Potassium, in very fine powder, *two troyounces and a half;* Distilled Water *eighteen fluidounces.* To the Water, heated to the boiling point in a glass vessel, add the powders, previously mixed, and boil for an hour; then filter the liquid while hot, and set it aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stopped bottle. By further evaporation the mother-water may be made to yield more crystals, which should be purified by a second crystallization." *U. S.* 1870.

† For still another method of preparing tartar emetic, which we omit from want of space, see *Journ. de Pharm.*, 4e sér., xi. 404.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; and it is not material what plan is adopted, provided the crystals of the antimonial salt be carefully purified. In an extensive manufactory in London, antimony ash is employed for boiling with the cream of tartar, and it is stated to form the cheapest material for making tartar emetic. (*Pereira's Mat. Med.*) Mohr prefers the use of a *moist* oxide, prepared by adding gradually an intimate mixture of one part, each, of antimony tersulphide and potassium nitrate to a boiling mixture of one part of sulphuric acid and two of water. The liquid is boiled down nearly to dryness and allowed to cool. The grayish-white mass thus formed is then washed thoroughly with water. The details of this process are given by Soubeiran, by whom it is praised, in the *Journ. de Pharm.*, 3e sér., iii. 327.*

Properties, etc. It is in the form of "colorless, transparent crystals of the rhombic system, becoming opaque and white on exposure to air; or a white, granular powder, without odor, and having a sweet, afterwards disagreeable, metallic taste. Soluble in 17 parts of water, at 15° C. (59° F.), and in three parts of boiling water, but insoluble in alcohol, which precipitates it from its aqueous solution in the form of a crystalline powder. When heated to 110° C. (230° F.), the salt loses its water of crystallization (2·71 per cent.). When heated to redness, it chars, emits an odor resembling that of burning sugar, and leaves a blackened residue having an alkaline reaction. The aqueous solution of the salt possesses a slightly acid reaction, and yields, with hydrochloric acid, a white precipitate soluble in an excess of the acid; but no precipitate occurs if tartaric acid had previously been added." *U. S.* Antimony and potassium tartrate was discovered in 1631 by Adrian de Mynsicht. When prepared from the oxychloride it crystallizes in tetrahedrons. As it occurs in commerce, it is often in the form of a white powder, resulting from the pulverization of the crystals. They are insoluble in alcohol, but dissolve in proof spirit or wine.† (See *Vinum Antimonii.*) Its aqueous solution slightly reddens litmus, and undergoes decomposition by keeping. If one-fifth of its bulk of alcohol be added to the water, the decomposition is prevented. It is incompatible with acids, alkalies and their carbonates, some of the earths and metals, calcium chloride, and lead acetate and subacetate. It is incompatible also with astringent infusions and decoctions, as of rhubarb, cinchona, catechu, galls, etc.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent.

Characteristics and Tests of Purity. "In a solution of the salt, acidulated with hydrochloric acid, hydrogen sulphide test-solution produces an orange-red precipitate. The aqueous solution, even when largely diluted, at once becomes permanently turbid on the addition of a small quantity of potassium carbonate or calcium hydrate test-solution. A 1-per cent. aqueous solution of the salt, acidulated with acetic acid, should not be affected by the addition of a few drops of barium chloride test-solution (absence of *sulphate*), silver nitrate test-solution (*chloride*), ammonium oxalate test-solution (*calcium*), or potassium ferrocyanide test-solution (*iron* and *other metals*). On adding sodium carbonate test-solution to crushed crystals of the salt, effervescence should not ensue (absence of *potassium bitartrate*). If 1 Gm. of the salt be dissolved, with the aid of heat, in hydrochloric acid, and to this solution 1 C.c. of stannous chloride test-solution be added (see List of Reagents, Bettendorff's Test for Arsenic), no turbidity or coloration should ensue within one hour (limit of *arsenic*). If 0.331 Gm. of the crystallized salt, or 0·322 Gm. of the salt dried at 110° C. (230° F.), be dissolved in 10 C.c. of water, and about 20 C.c. of a cold, saturated solution of sodium bicarbonate and a little starch test-solution added, it should require not less than 20 C.c. of iodine decinormal volumetric solution to produce a permanent blue color (corresponding to 100 per cent. of the pure salt)." *U. S.* "Each gramme dissolved in *water* with 2 or 3 grammes of *sodium bicarbonate* should discharge the color of not less than 60·2 nor more than 60·7 cubic centimetres of the *volumetric solution of iodine* quickly introduced from a burette. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, calcium, sodium, ammonium, chlorides, or sulphates. It should not effervesce with *solution of sodium bicarbonate* (absence of acid potassium tartrate). 1·66 grammes should dissolve slowly but without residue in 25

* *Antimony Tartrate* $(SbO)O_6C_4H_5$. Yuntz (*Archiv d. Pharm.*, 1887, p. 641) communicates the following process for this salt. An excess of antimony oxide is boiled with solution of tartaric acid, the clear solution evaporated to a syrupy consistence, allowed to cool, and the crystalline precipitate which forms washed with absolute alcohol to free it from any excess of tartaric acid.

† Alcohol precipitates it from its aqueous solution, and Mr. T. S. Wiegand proposes as a method of obtaining it in fine powder, to boil an ounce in four times its weight of water, and to pour the solution into a pint and a half of 95-per-cent. alcohol. (*A. J. P.*, 1858, p. 407.)

cubic centimetres of *water* at 60° F. (15·5° C.)." *Br.* Tartar emetic, when pure, exhibits its appropriate crystalline form. A crystal or two, dropped into a solution of hydrogen sulphide, will be covered with an orange-colored deposit of antimony tersulphide. Entire solubility in water is not a character belonging exclusively to the pure salt, for, according to the late Mr. Hennell, tartar emetic may contain 10 per cent. of uncombined cream of tartar and yet be wholly soluble in the proper proportion of water. Hennell's method of detecting uncombined bitartrate is to add a few drops of a solution of sodium carbonate to a boiling solution of the antimonial salt. If the precipitate formed be not redissolved, no bitartrate is present.

The impurities found in tartar emetic are uncombined cream of tartar from faulty preparation or fraudulent admixture, calcium tartrate, iron, sulphates, and chlorides. The mode of detecting cream of tartar has been indicated above. Calcium tartrate is derived from the cream of tartar, which always contains this impurity. It is apt to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Iron is sometimes present, especially when the antimonial salt has been prepared from glass of antimony. It is detected by a blue color being *immediately* produced by potassium ferrocyanide, added after a little acetic acid. If the blue color be *slowly* produced, it may arise from reactions on the iron of the ferrocyanide itself. If much iron be present, the solution of the tartar emetic will be yellow instead of colorless. According to Sérullas, tartar emetic, except when well crystallized, and all the other antimonial preparations usually contain a minute proportion of arsenic, derived from the native antimony tersulphide, which almost always contains this dangerous metal. Subsequently, however, Mr. Thos. Williams (*P. J. Tr.*, July, 1874, p. 63) examined a number of samples of various antimonial preparations and found them remarkably free from arsenic. Tartar emetic should always be bought by the apothecary in good crystals, in which state the salt is pure, or very nearly so, and entirely free from arsenic. Its powder is perfectly white; and, when it is yellowish white, iron is probably present. A. H. Jackson found some samples of commercial tartar emetic to contain from 40 to 70 per cent. of potassium sulphate. (*Year-Book of Pharmacy*, 1885, p. 459.)

It has been already stated in general terms that tartar emetic in solution is incompatible with acids and alkalies, and with some of the earths; but this salt is so important that some details in regard to the effects of particular reagents, included under these titles, seem to be necessary. Hydrochloric and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of antimony terchloride or subsulphate, mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of acid. When caustic potassa is added to a tolerably concentrated solution, it produces at first no effect, then a precipitate of teroxide, and afterwards the solution of this precipitate, if the addition of the alkali be continued. Lime water acts in a weaker solution, and throws down a white precipitate, consisting of the mixed calcium and antimony tartrates. Potassium carbonate affects still weaker solutions, throwing down a white precipitate of teroxide; but this test does not act in solutions containing less than a quarter of a grain to the fluidounce. Ammonia, both pure and carbonated, precipitates a solution of tartar emetic, throwing down the pure teroxide. To these reagents may be added infusion of galls, which, when fresh and strong, causes a dirty-yellowish-white precipitate of antimony tannate.

Medical Properties and Uses. When tartar emetic is given in minute doses to the healthy man (gr. $\frac{1}{12}$, or 0·005 Gm.) it produces only a slight lessening of the force of the pulse and a tendency to increased secretion from the skin. After somewhat larger amounts these symptoms are more pronounced, and have nausea added to them. If a grain be ingested, the nausea and vomiting will be severe and persistent, and accompanied by marked prostration, both of the circulation and of the muscular strength. Symptoms of acute poisoning by the drug are an austere metallic taste; excessive nausea; copious vomiting; frequent hiccough; burning pain in the stomach; colic; frequent stools and tenesmus; fainting; small, contracted, and accelerated pulse; coldness of the skin, and even of the internal organs; difficult and irregular respiration; cutaneous anæsthesia; loss of sense; convulsive movements; very painful cramps in the legs; prostration, and death. Ten grains is the smallest dose reported to have proved fatal. In the lower animals antimony causes symptoms similar to those which it produces in man. It has been experimentally proved that the fall of the arterial pressure is produced, at least in part, by a direct action upon the heart. The loss of muscular power, of reflex activity, and of sensibility is believed to be due to depression of the spinal centres, and the disturbance of respiration to a direct influence upon the nerve-

centres which preside over that function. The purging and vomiting are connected with an effort at elimination, the poison escaping through the gastro-intestinal mucous membrane, as well as through the kidneys. After death from antimony, fatty degeneration of the liver, kidneys, and other organs has been found, indicating that the poison has a powerful influence upon nutrition. It is evident that in small doses tartar emetic is powerfully depressant to the circulation and stimulant to the secretion of the skin. It has been very largely used as a sedative, antiphlogistic, diaphoretic, and expectorant. It is, however, at present much less frequently administered than formerly; in *small* doses (gr. $\frac{1}{12}$ to $\frac{1}{8}$, or 0·005 to 0·008 Gm.), mostly associated with saline, alkaline, or diaphoretic remedies, and assisted by copious dilution, it is still resorted to in *febrile complaints*, for the purpose of producing perspiration, which is often freely induced, especially if the remedy gives rise to nausea. It also proves useful, on many occasions, in the first stages of *bronchitis;* and with a view to its action in this way, it is conjoined with expectorant remedies. In *full* doses it acts as an emetic, and is characterized by certainty, strength, and permanency of operation. It remains longer in the stomach than ipecacuanha, produces more frequent and longer-continued efforts to vomit, and exerts a more powerful impression on the system. The nausea and attendant prostration are often very considerable. Its employment is contra-indicated by debility or gastro-intestinal irritability, and it is very badly borne by children.

The so-called contra-stimulant use of large doses of antimony originated with Dr. Rasori, professor of clinical medicine at Milan, who published his views in 1800, but has gone entirely out of vogue. The principal diseases in which it was practised were *pneumonia*, *pleurisy*, *bronchitis*, and *acute rheumatism*. The medicine was directed in doses varying from a grain to two grains (0·064 to 0·129 Gm.) or more every two hours, dissolved in a small quantity of water; the patient being restricted in the use of drinks whilst under its operation. It is stated that when the remedy is thus given in diseases of high action it seldom produces vomiting, an effect which the author of the practice wished to avoid. The power of the system to bear large doses of tartar emetic during the existence of acute diseases was considered by Rasori to depend upon the coexisting morbid excitement, and the capability of bearing them was expressed by the term *tolerance*.

Externally, tartar emetic is employed as a counter-irritant, mixed with lard, or cerate, or in the form of a plaster. It causes, after a longer or shorter interval, a burning sensation, accompanied by a peculiar and painful pustular eruption. This mode of producing counter-irritation is serviceable when a very powerful and persistent effect is desirable. Care must be taken that the pustular inflammation does not proceed too far; deep and very painful ulcerations, difficult to heal, may be produced.

Tartar emetic is generally given in solution, and in an amount which varies with the object in view in its administration. Its dose as an alterative is from the thirty-second to the sixteenth of a grain (0·002–0·004 Gm.); as a diaphoretic or expectorant, from the twelfth to the sixth of a grain (0·005–0·01 Gm.); and as a nauseating sudorific, from a sixth to a quarter of a grain (0·01–0·016 Gm.); repeated, according to circumstances, every hour, two, or four hours; as an emetic half a grain (0·03 Gm.), repeated every twenty minutes till it vomits; the operation being aided by warm water or chamomile tea.

Poisoning. The general symptoms of acute tartar emetic poisoning have been sufficiently described. In rare cases vomiting and purging do not take place; and when they are absent, the other symptoms are aggravated. Sometimes a pustular eruption is produced, like that caused by the external application of the antimonial.

When given in repeated small doses, tartar emetic produces both in man and in the lower animals a chronic poisoning, in which the chief symptoms are nausea, vomiting, watery purging, often followed by constipation, failing circulation, and a general asthenia, deepening into death from exhaustion. After death from antimonial preparations, decided evidences of gastro-intestinal irritation are apt to be present, but they have been in some cases wanting. The blood is often markedly fluid. Intense venous congestion, especially of the lungs, is usually present, and in some cases pulmonary apoplexy, atelectasis, or other structural lesion of the lungs has been found. A wide-spread fatty degeneration has been noted as constant in chronic poisoning in animals, and probably occurs also in man.

The treatment of tartar emetic poisoning consists, first, in washing out the stomach with a solution of tannic acid; second, in meeting the symptoms as they arise, especially by the use of opiates, which should be administered hypodermically and by rectal suppositories; external warmth, stimulants, etc., should be used *pro re nata*. In all cases of suspected poisoning, the

vomit, the passages from the bowels, and especially the urine, should be saved. The metal has been found in all the tissues of the body, but in the experiments of Dr. B. W. Richardson it was most abundant in the liver.

In examining the contents of the stomach or intestines for tartar emetic, they should be digested in water acidulated with hydrochloric and tartaric acids. The former acid will serve to coagulate organic matter; the latter to give complete solubility to the antimony. The solution obtained, after having been filtered, should be subjected to a stream of hydrogen sulphide, which, if tartar emetic be present, will throw down the orange-red antimony tersulphide, distinguished from arsenic tersulphide and all other precipitates by forming with hot hydrochloric acid a solution, from which a white curdy precipitate of antimony oxychloride (powder of Algaroth) is thrown down upon the addition of water. Hydrogen sulphide is by far the most delicate test for tartar emetic.

The mode of extracting the antimony from the solid tissues, recommended by Orfila, is to carbonize the dried viscera with pure concentrated nitric acid in a porcelain capsule, to boil the charred mass obtained for half an hour with hydrochloric acid, assisted with a little nitric acid, to filter the liquor, and introduce it into Marsh's apparatus. Hydrogen antimonide will be formed, which, being inflamed, will deposit the antimony on a cold surface of porcelain as a black stain, distinguishable from the similar stain produced by arsenic by its slighter volatility, by its forming with hot hydrochloric acid a solution which affords a white precipitate of antimony oxychloride when added to water, by its insolubility in solution of bleaching powder or chlorinated soda, and by its solubility in solution of stannous chloride. (See *Acidum Arsenosum.*)

Reinsch's process is a good one for separating antimony from the tissues, and was first used for that purpose by Dr. Alfred Taylor, of London. The tissues are boiled in hydrochloric acid, and a bright slip of copper is immersed in the hot solution. The metallic film deposited on the copper must be proved to be antimony. This is done by Dr. Odling by first boiling the coated copper in a solution of potassium permanganate, with a little excess of potassa, for a few minutes, whereby the antimony becomes oxidized and dissolved, and then passing hydrogen sulphide through the filtered and acidulated solution. The characteristic orange-red precipitate of antimony tersulphide is produced, which may be tested for antimony as above mentioned. Mr. H. H. Watson has simplified Dr. Odling's process by dispensing with the use of the potassium permanganate. He subjects the coated copper slip, in a tube, to a boiling very dilute solution of caustic potassa, the metal being alternately drawn out of and immersed in the solution, by the aid of a copper wire, until the whole of the coating is oxidized and dissolved. The solution is then treated as directed by Dr. Odling. (*Med. Times and Gaz.*, July, 1857, p. 613.) Hydrogen antimonide (evolved either by galvanic processes or from zinc and sulphuric acid), when passed over sulphur, is decomposed, slowly in diffused daylight, very rapidly in sunlight, antimony sulphide forming, with liberation of hydrogen sulphide. The orange-red sulphide can be freed from excess of sulphur by exhaustion with carbon disulphide. (Jones, *Journ. Chem. Soc.*, i., 1876.)

ANTIMONII OXIDUM. U. S., Br. Antimony Oxide. [Antimony Trioxide.]

Sb_2O_3; 287·08. (ĂN-TĪ-MŌ'NĪ-Ī ŎX'Ī-DŬM.) Sb_2O_3; 288.

"Antimonious Oxide, Sb_4O_6, may be prepared by pouring solution of antimonious chloride into water, and decomposing the precipitated antimony oxychloride with sodium carbonate." *Br.*

Oxide of Antimony; Stibium Oxydatum, Oxydum Antimonicum s. Stibicum; Oxyde d'Antimoine, *Fr.*; Antimonoxyd, *G.*

A process for this salt is no longer official in the U. S. P. 1890. Below is that of the Pharm. 1870.*

* "Take of Sulphuret of Antimony, in very fine powder, *four troyounces*; Muriatic Acid *eighteen troyounces*; Nitric Acid *a troyounce and one hundred and twenty grains*; Water of Ammonia *a fluidounce and a half*; Water, Distilled Water, each, *a sufficient quantity*. Introduce the Sulphuret into a flask, of the capacity of two pints, and, having added the Muriatic Acid, digest, by means of a sand-bath, until effervescence ceases. Then, having removed the flask from the sand-bath, add the Nitric Acid gradually; and, when nitrous acid vapors cease to be given off, and the liquid has grown cold, add to it half a pint of Water, and filter. Pour the filtered liquid gradually into twelve pints of Water, constantly stirring, and allow the precipitate to subside. Decant the supernatant liquid, and wash the precipitate twice by decantation, using, each time, eight pints of Water. Then transfer it to a muslin filter to drain, and, after the draining is completed, wash it with Water until the washings cease to have an acid reaction. Next introduce it into a suitable vessel, and subject it to the action of the Water of Ammonia for two hours; at the end of which time transfer it to a moistened muslin filter, and wash it with Distilled Water as long as the washings produce a precipitate with nitrate of silver. Lastly, dry the precipitate upon bibulous paper with the aid of a gentle heat." *U. S.* 1870.

When antimony tersulphide is digested with hydrochloric acid, a chemical reaction takes place as follows: $Sb_2S_3 + 6HCl = (SbCl_3)_2 + (H_2S)_3$; the hydrogen of the acid uniting with the sulphur of the antimonial, and escaping as hydrogen sulphide, while the chlorine and antimony combine to form antimony terchloride, which is held in solution. The effect of the nitric acid is supposed to be to render the oxide whiter, by decomposing any remaining hydrogen sulphide, and thus preventing it from contaminating the product. Though the result thus far is an aqueous solution of the terchloride, this cannot be diluted beyond a certain degree without decomposition. Hence, if largely diluted, as when poured into an excess of water, decomposition takes place, and a white powder is precipitated, formerly called *powder of Algaroth*, which is mainly an oxychloride. The decomposition of the powder, however, is not uniform, as it contains more teroxide the greater the proportion of water used in the decomposition. The pure oxychloride, SbOCl, is formed when the proportion of 4 mols. of water to 1 mol. of antimony chloride exists, but with a relatively larger proportion of water the average composition of the powder is $Sb_4O_5Cl_2$, which may be considered as made up of $(SbOCl)_2 + Sb_2O_3$. The oxychloride is first washed with abundance of water to separate adhering hydrochloric acid, and then acted upon by a solution of alkali (Ammonia, *U. S.*, Carbonate of Sodium, *Br.*) to decompose the oxychloride, with the effect of adding to the amount of teroxide; after which the teroxide requires only to be washed with water in order to render it pure. The last washing separates the ammonium or sodium chloride resulting from the decomposition of the oxychloride; and the water of this washing is tested, in both formulas, by silver nitrate, until the presence of chlorine ceases to be indicated.

Properties. Antimony teroxide is a heavy, grayish-white powder, permanent in the air, almost insoluble in water, insoluble in alcohol and nitric acid, readily soluble in hydrochloric or tartaric acid, or in boiling solution of potassium bitartrate. Heated in close vessels it becomes yellow, fuses at a full red heat, and finally sublimes in crystalline needles. When cooled from a state of fusion, it forms a fibrous crystalline mass, of pearl color. Heated in open vessels it suddenly becomes red hot, and, by the absorption of oxygen, changes into Sb_2O_4 (antimony antimonate), which differs from the teroxide in being insoluble in hydrochloric acid, less fusible, and not volatile. This oxide is the active ingredient of all the medicinal preparations of antimony. "On dropping its solution in hydrochloric acid into water, a white precipitate is produced, which is at once changed to orange by hydrogen sulphide test-solution. If 1 Gm. of the Oxide be dissolved with the aid of 5 Gm. of tartaric acid in a little water, and the solution diluted with water to the measure of 100 C.c., portions of this solution should not be affected by test-solutions of silver nitrate (absence of *chloride*), barium chloride (*sulphate*), or potassium ferrocyanide (*iron* and *other metals*). If a solution of the Oxide in hydrochloric acid be diluted with water, until it just begins to become permanently turbid, and then precipitated with hydrogen sulphide, this precipitate, when collected and thoroughly washed, should be completely soluble in ammonium sulphide test-solution (absence of *copper* and *lead*). If 1 Gm. of the Oxide be dissolved in hydrochloric acid, and to this solution 1 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic) be added, no turbidity or coloration should ensue within one hour (limit of *arsenic*)." *U. S.* "If 0·5 gramme be dissolved in a hot solution of 1 gramme of Acid Potassium Tartrate and the solution then made alkaline with 3 grammes of *sodium bicarbonate*, the cooled liquid should discharge the color of 70 cubic centimetres of the *volumetric solution of iodine*. Antimonious Oxide should yield no characteristic reaction with the tests for lead, copper, arsenium, calcium, sodium, or potassium, only slight reactions with the tests for iron, and only the slightest reactions with the tests for chlorides or sulphates. It should dissolve entirely when boiled with an excess of Acid Potassium Tartrate." *Br.* It is frequently impure from the presence of the before-mentioned antimony antimonate, in which case it is not *entirely* soluble in hydrochloric acid. If it contain oxychloride, which it is apt to do from the imperfect action of the alkaline solutions employed in its purification, its solution in tartaric acid will be precipitated by silver nitrate. When antimony antimonate is substituted for it, the fraud may be detected by the spurious preparation being entirely insoluble in hydrochloric acid.

Medical Properties. This oxide, which must not be confounded with the powder of Algaroth, has the general therapeutic properties of the antimonials. Like antimonial powder, it is unequal in its effects, and ought not to be used in practical medicine. The inequality of action is plausibly explained by the state of the stomach as to acidity, the presence of acids giving the medicine activity; and this explanation is confirmed by the experi-

ments of Dr. Osburn, of Dublin, with the Dublin oxide. As to the French Codex oxide, prepared by boiling the oxychloride with a solution of potassium bicarbonate, the inequality is attributed by M. Durand, of Caen, to the presence of more or less terchloride, which is separated with difficulty. Objecting to the Codex oxide, M. Durand proposes to prepare the teroxide by precipitating tartar emetic with ammonia in excess. Thus obtained it contains no terchloride, and does not vomit. (*Journ. de Pharm.*, 3e sér., ii. 364.) The dose of antimony teroxide is set down as three grains (0·20 Gm.) every two or three hours, but the drug should not be employed as a medicine. It was introduced into the U. S. Pharmacopœia to be used in the preparation of tartar emetic, and as an ingredient in Pulvis Antimonialis.

ANTIMONII SULPHIDUM. U. S. Antimony Sulphide. [Antimony Trisulphide.]

Sb_2S_3; 335·14. (ĂN-TĮ-MŌ'NĮ-Ī SŬL'PHĮ-DŬM.) Sb_2S_3; 336.

"Native antimony sulphide, purified by fusion and as nearly free from arsenic as possible." *U. S.*

Antimonium Nigrum, *Br.* 1864; Black Antimony. (Prepared Sulphuret of Antimony, *Br.*) Stibium Sulfuratum Crudum et Lævigatum, *P. G.;* Antimonium Crudum, Stibium Sulfuratum Nigrum, Sulfuretum Stibicum; Artificial Sulphuret of Antimony; Antimoine sulfuré, Sulfure d'Antimoine, Antimoine cru, *Fr.;* Schwefelantimon, Schwefelspiessglanz, *G.;* Solfuro d'Antimonio, *It.;* Antimonio crudo, *Sp.*

Preparation, etc. The antimony sulphide of the Pharmacopœias is obtained from the native sulphide, called *antimony ore*, by different processes of purification; the following being an outline of that generally pursued. The ore is placed in melting-pots in a circular reverberatory furnace, and these are made to connect, by means of curved earthen tubes, with the receiving-pots, situated outside the furnace. This arrangement affords facilities for removing the residue of the operation, and allows of the collection of the melted sulphide without interrupting the fire, and, consequently, without loss of time or fuel. In the U. S. Pharmacopœia it is directed to be melted in order to purify it from infusible substances; in the British, to be reduced to fine powder, to fit it for pharmaceutic use. In order to bring it to this state, it should be submitted to the process of levigation. (See *Antimonii Sulphidum Purificatum.*) Much of the "Black Antimony" of commerce has been shown by Prof. Warder to contain no antimony whatever, but to be simply powdered coal and marble, and such can be easily distinguished by a rough test, as follows. Fill a dry, tared one-ounce bottle with the powder: after shaking it down it will be found that it will hold two and a quarter ounces of powdered black antimony, but only one and a quarter ounces of powdered coal. (*Proc. A. P. A.*, 1885, p. 479; see, also, S. W. McKeown's paper, *Proc. Ohio State Pharm. Assoc.*, 1885.)

Properties. Antimony sulphide is mostly prepared in France and Germany. It is called, in commerce, antimony, or *crude antimony*, and occurs in fused conical masses, denominated loaves. "Steel-gray masses of a metallic lustre and a striated crystalline fracture, forming a black or grayish-black, lustreless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At a temperature below a red heat, the Sulphide fuses to a dark brown liquid. If 1 Gm. of the powdered Sulphide be digested and finally boiled with 10 C.c. of hydrochloric acid, it should dissolve without leaving more than 1 per cent. of residue. This acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which is soluble in a solution of tartaric acid. After the separation of the precipitate by filtration, the filtrate yields an orange-red precipitate with hydrogen sulphide test-solution." *U. S.* The quality of the sulphide cannot well be judged of, except in mass; hence it ought never to be bought in powder. Arsenic, which is often present in considerable quantities, may be detected by the usual tests for that metal. (See *Acidum Arsenosum*, p. 19.)

The official antimony sulphide is a tersulphide consisting of two atoms of antimony and three of sulphur. When prepared by pulverization and levigation, it is in the form of an insoluble powder, without taste or smell, usually of a dull blackish color, but reddish brown when perfectly pure. By exposure to the air, it absorbs, according to Buchner, a portion of oxygen, and becomes partially converted into teroxide.

Medical Properties and Uses. This preparation is very uncertain in its operation, and ought not to be used in practical medicine. It has, however, been employed as a diaphoretic and alterative in *scrofula*, *glandular obstructions*, *cutaneous diseases*, and *chronic rheumatism*. It is used in the United States solely in veterinary practice. The dose is from ten to thirty grains (0·65–1·95 Gm.), in powder or bolus.

ANTIMONII SULPHIDUM PURIFICATUM. U. S. (Br.) Purified Antimony Sulphide. [Purified Antimony Trisulphide.]

Sb_2S_3; 335·14. (ĂN-TĮ-MŌ'NĪ-Ī SŬL'PHĮ-DŬM PŪ-RĮ-FĮ-CĀ'TŬM.) Sb_2S_3; 336.

"Native antimonious sulphide, Sb_2S_3, from which siliceous matter has been removed by fusion, reduced to fine powder, and, if any salt of arsenium be present, purified by digesting with half its weight of solution of ammonia for several days, washing and drying." *Br.*

Antimonium Nigrum Purificatum, *Br.;* Antimonious Sulphide; Purified Black Antimony.

"Antimony Sulphide, *one hundred grammes* [or 3 ounces av., 231 grains]; Ammonia Water, *fifty cubic centimeters* [or 1 fluidounce, 5½ fluidrachms]; Water, *a sufficient quantity.* Reduce the Antimony Sulphide to a very fine powder. Separate the coarser particles by elutriation, and, when the finely-divided sulphide has been deposited, pour off the water, add the Ammonia Water, and macerate for five days in a well-closed vessel, agitating the mixture frequently. Then let the powder settle, pour off the Ammonia Water, and wash the residue by repeated affusion and decantation of Water. Finally dry the product by the aid of a gentle heat." *U. S.*

The test for arsenum is as follows. "If one grain be dissolved in hydrochloric acid, and the solution, slightly diluted, be gently warmed with a piece of bright copper foil, the copper being washed, dried, and heated in a dry, narrow test-tube, no crystalline sublimate (of arsenous anhydride) should form on the upper cool part of the tube." *Br.* (1885).

These are new official processes, which are intended to furnish a black antimony sulphide better fitted for the manufacture of the official preparations of antimony and for internal administration. Copper, a common impurity in the crude sulphide, is rendered soluble by the water of ammonia, whilst the subsequent washing and decantation effectually remove all soluble impurities. (See *Antimonii Sulphidum.*)

Properties. "A heavy, grayish-black, lustreless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At a temperature below a red heat it fuses to a dark brown liquid." *U. S.*

Tests. "If 1 Gm. of the Sulphide be digested, and finally boiled, with 10 C.c. of hydrochloric acid, it should dissolve without leaving more than 1 per cent. of residue. This acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which is soluble in a solution of tartaric acid. After the separation of the precipitate by filtration, the filtrate yields an orange-red precipitate with hydrogen sulphide test-solution. If 2 Gm. of the Sulphide be mixed and cautiously ignited, in a porcelain crucible, with 8 Gm. of pure sodium nitrate, and, after cooling, the fused mass be boiled with 25 C.c. of water, there will remain a residue which should be white or nearly so, and not yellowish nor brownish (absence of *other metallic sulphides*). On boiling the filtrate separated from the last-mentioned residue with a slight excess of nitric acid, until no more nitrous vapors are evolved, then dissolving in it 0·1 Gm. of silver nitrate, filtering again if necessary, and cautiously pouring a few drops of ammonia water on top, not more than a white cloud, but no red or reddish precipitate, should appear at the line of contact of the two liquids (absence of more than about 0·1 per cent. of *arsenic*)." *U. S.* "A grayish-black crystalline powder decomposed on boiling with *hydrochloric acid*, an almost clear solution being formed and hydrogen sulphide escaping. The solution affords the reactions characteristic of antimony. It should not yield more than slight characteristic reactions with the tests for arsenium." *Br.*

Medical Properties and Uses. This preparation, introduced into the Pharmacopœias for pharmaceutical purposes, should not be used in medical practice.

ANTIMONIUM SULPHURATUM. U. S., Br. Sulphurated Antimony. [Kermes Mineral.]

(ĂN-TĮ-MŌ'NĮ-ŬM SŬL-PHŪ-RĀ'TŬM.)

"Chiefly Antimony Trisulphide [$Sb_2S_3 = 335·14$], with a very small amount of Antimony Trioxide." *U. S.* "A mixture containing antimony sulphides and oxides, Sb_2S_5, Sb_2O_5, Sb_2S_3, Sb_4O_6, and sulphur." *Br.*

Antimonii Oxysulphuretum, *Lond.;* Antimonii Sulphuretum Aureum, *Ed.;* Precipitated Sulphide of Antimony; Stibium Sulfuratum Aurantiacum, *P. G.;* Sulphur Stibiatum Aurantiacum, Sulphur Auratum Antimonii; Golden Sulphuret of Antimony, Golden Sulphur; Soufre doré d'Antimoine, *Fr.;* Goldschwefel, *G.*

The U. S. Pharmacopœia of 1890 added the synonyme "Kermes Mineral" to this preparation, intending that this should be used when that was ordered in prescriptions.

"Purified Antimony Sulphide, *one hundred grammes* [or 3 ounces av., 231 grains]; Solution of Soda, *twelve hundred cubic centimeters* [or 40 fluidounces, 4 fluidrachms, 37 minims]; Dis-

tilled Water, Diluted Sulphuric Acid, each, *a sufficient quantity*. Mix the Purified Antimony Sulphide with the Solution of Soda and *three thousand cubic centimeters* [or about 6¼ pints] of Distilled Water, and boil the mixture over a gentle fire for two hours, with frequent stirring, and occasionally adding Distilled Water so as to preserve the same volume. Strain the liquid immediately through a double muslin strainer, and drop into it, while yet hot, Diluted Sulphuric Acid so long as it produces a precipitate. Wash the precipitate with hot Distilled Water until the washings are at most but very slightly clouded by barium chloride test-solution; then dry the precipitate at a temperature not exceeding 25° C. (77° F.), and rub it to a fine powder. Keep the product in well-stoppered bottles, protected from light." *U. S.*

"Antimonious Sulphide, 10 *ounces* (Imperial) or 200 grammes; Sublimed Sulphur, 10 *ounces* (Imp.) or 200 grammes; Caustic Soda, of commerce, 5 *ounces* (Imp.) or 100 grammes; Diluted Sulphuric Acid, Distilled Water, of each a sufficient quantity. Dissolve the caustic soda in *five pints* (Imp. meas.) or two thousand cubic centimetres of the Distilled Water; with this solution mix the Antimonious Sulphide and the Sublimed Sulphur; boil for two hours with frequent stirring, adding Distilled Water occasionally to maintain the same volume; then, while the whole is still hot, add *nine pints* (Imp. meas.) or three thousand six hundred cubic centimetres of boiling Distilled Water; strain the product through calico; before the strained liquid cools add to it by degrees the Diluted Sulphuric Acid till the latter is in slight excess; collect the precipitate on a calico filter; wash with Distilled Water till the washings are free from sulphates; dry at a temperature not exceeding 212° F. (100° C.)." *Br.*

There are three preparations containing antimony and sulphur,—viz., the *amorphous precipitated antimony sulphide*, Sb_2S_3, which while orange-red in color corresponds to the black native sulphide; a reddish-brown mixture known as "*kermes mineral*," which contains both antimony sulphide and oxide, and has an average composition $(Sb_2S_3)_2 + Sb_2O_3$;* and the

* Antimonii Oxysulphuretum. *U. S.* 1870. *Oxysulphuret of Antimony. Kermes Mineral. Kermes mineral* was official in 1870. The following is the process. "Take of Sulphuret of Antimony, in very fine powder, *a troyounce;* Carbonate of Sodium *twenty-three troyounces;* Water *sixteen pints*. Dissolve the Carbonate of Sodium in the Water previously heated to the boiling point, and, having added the Sulphuret of Antimony, boil for an hour. Then filter rapidly into a warm earthen vessel, cover this closely, and allow the liquid to cool slowly. At the end of twenty-four hours, decant the supernatant liquid, drain the precipitate on a filter, wash it with boiled water previously allowed to become cold, and dry it without heat. Lastly, preserve the powder in a well-stopped bottle, protected from the light." *U. S.* A useless preparation, on account of its uncertainty of action.

Kermes mineral, according to Thénard, may be obtained by treating antimony tersulphide in three ways: 1st, with a boiling solution of the carbonated alkalies, 2d, with a boiling solution of the caustic alkalies, and, 3d, with the carbonated alkalies at a red heat. These several processes give brown powders, which vary in their shade of color, and which, though usually considered as identical, differ in composition. The kermes obtained by means of the carbonated alkalies in solution is an oxysulphide, that is, a compound of hydrated antimony tersulphide with the teroxide; while the product when either the caustic alkalies in solution or the carbonated alkalies at a red heat are used is essentially a hydrated tersulphide, though containing occasionally a little oxysulphide. It is the first of these methods that was adopted in the U. S. process of 1870. It is, in fact, the formula of Cluzel (see U. S. D., 11th ed., p. 926), and is substantially that of the French Codex of 1837.

The rationale of the formation of kermes by this process is as follows. A portion of the sodium carbonate is converted, by a transfer of carbonic acid, into caustic soda and sesquicarbonate. By a double decomposition taking place between a part of the antimony tersulphide and the caustic soda, sodium sulphide and antimony teroxide are formed. The undecomposed portion of the tersulphide then dissolves in the solution of sodium sulphide, and the teroxide in that of the remaining sodium carbonate. The tersulphide and teroxide, being both more soluble in these menstrua hot than cold, precipitate together as the liquid cools, and constitute this variety of kermes. Thus obtained it is light, velvety, of a dark reddish-purple color, brilliant in the sun, and of a crystalline appearance. It consists, according to M. Henry, jun., of antimony tersulphide 62·5, teroxide 27·4, water 10, and soda a trace; proportions which correspond most nearly with two mols. of tersulphide, one of teroxide, and six of water. From the presence of so large a proportion of antimony teroxide in this variety of kermes, it must be far more active than the other kinds, and ought, therefore, to be preferred for medical use.

Kermes, when obtained by means of the caustic alkalies, may be formed by the use of either potassa or soda. When the former alkali is selected, it may be prepared by boiling, for a quarter of an hour, two parts of antimony tersulphide with one part of caustic potassa dissolved in twenty-five or thirty parts of water, filtering the liquor, and allowing it to cool; whereupon the kermes precipitates. In this process one portion of the tersulphide, by reacting with a part of the potassa, gives rise to antimony teroxide and potassium sulphide. A second portion dissolves in the solution of potassium sulphide formed, and a third forms an insoluble compound with a part of the teroxide. The remainder of the teroxide unites with the undecomposed potassa, forming a compound which, being but sparingly soluble, is only in part dissolved. The hot filtered liquor, therefore, contains this compound dissolved in water, and antimony tersulphide dissolved in the solution of potassium sulphide. By refrigeration, the tersulphide in a hydrated state falls down, free or nearly free from teroxide, this latter being still held in solution by means of the caustic alkali.

Kermes may be obtained by the third method, that is, in the dry way, by the use of the carbonated alkalies at a red heat. If potassium carbonate * be selected, the process is as follows. Rub together two parts of antimony tersulphide and one of potassium carbonate, fuse the mixture in a crucible by a red heat, reduce the fused mass to

* According to the researches of M. A. Terreil (*Journ. de Pharm.*, 4e sér., xix. 131), potassium carbonate if absolutely pure will not yield kermes by the moist way, but by the dry way will give a larger yield than will sodium carbonate.

golden sulphide, which is antimonic sulphide, Sb_2S_5, and is obtained by decomposing sulph-antimonates like *Schlippe's salt* (SbS_4Na_3) by the addition of a strong mineral acid.

The first of these may be obtained by dissolving the powdered native sulphide in caustic potash solution with the aid of heat, and then adding to this solution, which contains the antimony combined as potassium antimonite and sulph-antimonite, sulphuric acid, when a reddish precipitate is formed which dries to a reddish-brown powder.

The second may be obtained by boiling the native sulphide or the red amorphous sulphide just described with sodium carbonate, and then allowing the compound to settle out from the hot filtered liquid as it cools.

The third may be obtained by first forming a sulph-antimonate by boiling finely-powdered antimony sulphide and caustic soda with sulphur (or sodium carbonate and chalk instead of the caustic soda), and then adding the solution of this to dilute hydrochloric or sulphuric acid, when yellow Sb_2S_5 separates, according to the reaction

$$2(SbS_4Na_3 + 9H_2O) + 3H_2SO_4 = 3Na_2SO_4 + Sb_2S_5 + 3H_2S + 18H_2O.$$

Ten parts of Schlippe's salt yield in theory 4·17 parts of antimony pentasulphide. The U. S. sulphurated antimony belongs to the first kind above mentioned, the British (1898) to the third variety. E. G. Eberhardt recommends the more direct preparation of sulphurated antimony by treating the native sulphide with hydrochloric acid and precipitating the solution with hydrogen sulphide. The objection that arsenic might be found in the product was met by an examination which showed that traces of arsenic present were not more than when the official process had been employed. (*A. J. P.*, 1886, p. 229.) The color of sulphurated antimony or kermes mineral is influenced by porphyrization, with the admixture of a little sugar or gum; if hastily porphyrized, the mixture has a violet tint; if carefully and slowly, it has a russet color.

Properties of the Precipitated Antimony Sulphide. (*Sulphurated Antimony, U. S., Br.*) "An amorphous, reddish-brown powder, becoming lighter in color on exposure to light, and having neither odor nor taste. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. When heated in a dry test-tube, it emits moisture and leaves a black residue. If 1 Gm. of Sulphurated Antimony be gently heated with 10 C.c. of hydrochloric acid, it should dissolve, with the exception of a slight residue, which, when washed and dried, should burn on the application of a flame with the characteristic odor of sulphur, leaving not more than a scanty ash. The acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which, after being washed and dried, should weigh not less than 85 per cent. of the original weight of the sulphide. The liquid filtered from this precipitate yields an orange-red precipitate with hydrogen sulphide test-solution. If 1 Gm. of Sulphurated Antimony be shaken with 20 C.c. of hot water, the filtrate should be neutral to test-paper, should not be rendered more than slightly opalescent by barium chloride test-solution (limit of *sulphate*), or silver nitrate test-solution (limit of *chloride*), and should not be affected by ammonium oxalate test-solution (absence of *calcium*). When tested for arsenic, as described under Purified Antimony Sulphide, it should afford no reaction beyond the limit prescribed for the latter." *U. S.* "A dull-red powder, readily dissolved by *solution of sodium hydroxide*, also by hot *hydrochloric acid* with the evolution of hydrogen sulphide and the separation of sulphur. 3 grammes moistened and warmed with successive portions of *nitric acid* until red fumes cease to be evolved, and then dried and heated to redness, should leave a white residue weighing about 2 grammes. Sulphurated Antimony should not yield more than the slightest characteristic reactions with the tests for arsenium." *Br.* Water in which this preparation has been boiled should not yield a white precipitate with ammonium oxalate. The non-action of this test shows the absence of

powder, boil it with water, and strain. As the strained liquor cools, the kermes is deposited. The rationale of its formation is nearly the same with that of the formation of the second variety of kermes. An inferior kermes, prepared in the dry way, and intended for use in veterinary medicine, is directed in the French Codex of 1837 to be prepared by fusing together, well mixed, 500 parts of antimony tersulphide, 1000 of potassium carbonate, and 30 of washed sulphur, reducing the fused mass to powder, and boiling it with 10,000 parts of water. The liquor, upon cooling, lets fall the kermes, which must be washed with care and dried.

Kermes mineral, as usually found in commerce, is an insipid, inodorous powder, of a purplish-brown color, and soft and velvety to the touch. By the action of air and light it gradually becomes lighter colored, and at last yellowish white. It is readily and wholly dissolved by hydrochloric acid, with escape of hydrogen sulphide gas, and is partly soluble in a hot solution of potassa, leaving a residue soluble in tartaric acid. It is sometimes adulterated with ferric oxide. In Paris, in 1849, a number of the shops contained a spurious kermes of very handsome appearance which was little else than this oxide. Kermes mineral first came into use as a remedy in France about the beginning of the last century. Its mode of preparation was possessed as a secret by a French surgeon named La Ligerie. In 1720 the recipe was purchased by the French government and made public.

lime. When pure, precipitated antimony sulphide is completely soluble in a hot solution of potassa; but, as it is found in commerce, a white matter is usually left undissolved. When boiled with a solution of cream of tartar, about 12 per cent. of teroxide is dissolved; but, according to H. Rose, this method of determining the proportion of the teroxide cannot be relied on. Exposed to heat it takes fire, and burns with a greenish-blue flame, giving off sulphurous acid, while the metal remains behind in the state of a grayish oxide.

The London precipitated antimony sulphide, as analyzed by Mr. Phillips, consisted, in the 100 parts, of tersulphide 76·5, teroxide 12, and water 11·5; proportions corresponding nearly with five mols. of tersulphide, one of teroxide, and fifteen of water. It usually contained a portion of pentasulphide, as shown by the action of hydrochloric acid, which, when heated with this antimonial, forms the terchloride with disengagement of sulphur. (*Gmelin's Handbook*, iv. 989.) Its active ingredient is the teroxide; and in reference to its presence the London College called the preparation *oxysulphuret of antimony*. The Edinburgh College named it incorrectly *golden sulphuret of antimony;* this name being properly applicable to the precipitate produced by the sole action of acids, and not to that obtained by the action of acids and refrigeration conjointly.

Mr. John Moss asserted before the London Pharmaceutical Society that the British process always yields a dark reddish or reddish-brown powder, but that the kermes mineral in English commerce is golden yellow or yellowish red, and must be prepared by some other method. He was confirmed by Profs. Redwood and Attfield; the latter explaining that the official kermes contains antimony tersulphide, the commercial, antimony pentasulphide.

Medical Properties. *Precipitated antimony sulphide* (*sulphurated antimony*) is alterative, diaphoretic, and emetic. It is, however, an uncertain medicine, and is very little used. In combination with calomel and guaiac (*Plummer's pill*), it was formerly employed in *secondary syphilis* and *cutaneous eruptions*. (See *Pilulæ Antimonii Compositæ*.) During its use the patient should abstain from acidulous drinks. Its dose as an alterative is from one to two grains (0·064 to 0·129 Gm.), given twice a day, in the form of pill; as an emetic, from five grains to a scruple (0·323 to 1·29 Gm.).

Golden sulphide acts like kermes mineral, but is much weaker, and must be given in a larger dose.

APOCYNUM. U. S. Apocynum. [Canadian Hemp.]

(Ă-PŎC'Y-NŬM.)

"The root of Apocynum cannabinum, Linné (nat. ord. Apocynaceæ)." *U. S.*

Chanvre du Canada, *Fr.;* Canadische Hanfwurzel, *G.*

Gen. Ch. Calyx five-parted, the lobes acute. *Corolla* bell-shaped, five-cleft, bearing five triangular appendages in the throat opposite the lobes. *Stamens* five, inserted on the very base of the corolla. *Filaments* flat, shorter than the arrow-shaped anthers, which converge round the ovoid, obscurely two-lobed stigma, and are slightly adherent to it by their inner face. *Style* none. *Stigma* large, ovoid, slightly two-lobed. *Fruit* two long slender follicles. *Gray's Manual.*

There are two indigenous species of this genus, *A. cannabinum*, L., and *A. androsæmifolium*, L., of very similar general aspect. Both plants abound in a milky juice, and have a tough fibrous bark, which, by maceration, affords a substitute for hemp; hence the common name.

In the official species the stems and branches are upright or ascending, terminated by erect and close, many-flowered cymes, which are usually shorter than the leaves, and the corolla has nearly erect lobes, with the tube not longer than the lanceolate divisions of the calyx. In *A. androsæmifolium* the branches are divergently forked, the cymes loose and spreading, the open bell-shaped corolla with revolute lobes and a tube much longer than the ovate-pointed divisions of the calyx. The two plants grow together, although *A. cannabinum* seems to be proportionately more common in the West. *A. androsæmifolium* was formerly included in the U. S. secondary list, but seems to have almost disappeared from the market. According to Mr. Edward A. Manheimer, its root can be distinguished from that of *A. cannabinum* on microscopic examination by the thick-walled bast-cells, which are arranged somewhat in a circle near the middle of the bark. (*A. J. P.*, Nov. 1881. See also *A. J. P.*, 1888.) Prof. C. B. Lowe (*A. J. P.*, 1896) asserts that dogsbane (*A. androsæmifolium*) is subject to frequent substitution by *A. cannabinum*, the latter being very abundant.

The root of *A. cannabinum* is horizontal, five or six feet in length, about one-third of an inch thick, dividing near the end into branches which terminate abruptly, of a yellowish-brown color when young, but dark chestnut when old, of a strong odor, and a nauseous, somewhat acrid, permanently bitter taste. The internal or ligneous portion is yellowish white, and less

bitter than the exterior or cortical part. "Long, cylindrical, somewhat branched, 5 to 10 Mm. thick, gray or brownish-gray, longitudinally wrinkled and transversely fissured; brittle, fracture short, white; the bark rather thick; the wood porous, spongy, with delicate, medullary rays; inodorous; taste bitter, disagreeable." *U. S.* The fresh root, when wounded, emits a milky juice, which concretes into a substance resembling caoutchouc. In the dried state, it is brittle and readily pulverized, affording a powder like that of ipecacuanha. Schmiedeberg and te Water (*Pflanzenstoffe*, 2d ed., p. 1332) found two principles acting like digitalin: one, an amorphous resinous substance, not a glucoside, easily soluble in alcohol and ether, almost insoluble in water, which is called *apocynin*, and the other, a glucoside, easily soluble in water, which is known as *apocyneïn*. Neither of the principles gives any color reaction with sulphuric acid and bromine. The root yields its virtues to water and alcohol, but, according to Dr. Griscom, more readily to the former. Prof. J. U. Lloyd noticed a white, tasteless, crystalline, waxy precipitate formed in a fluid extract of *A. cannabinum*. Von Oefele (*Journ. Pharm. Elsass-Lothr.*, 1891, 325) describes *apocynteine*, an alkaloid obtained from *A. venetum;* it is said to be a cardiac sedative.

Medical Properties and Uses. Apocynum (or, as it is frequently improperly called, *Indian Hemp*) is powerfully emetic and cathartic, sometimes diuretic, and promotes diaphoresis and expectoration. It produces much nausea, diminishes the frequency of the pulse, and appears to induce drowsiness independently of the exhaustion consequent upon vomiting. According to D. A. Sokoloff (*Medical Chronicle*, Sept. 1888), apocynum, in sufficient dose, first stimulates the heart and the vaso-motor centres, causing a pronounced rise of the arterial pressure, and then acts as a paralyzant, producing a gradual fall of the pressure to zero. The disease in which apocynum has been found most beneficial is *dropsy*. From fifteen to thirty grains (1–1·95 Gm.) of the powdered root will generally produce copious vomiting and purging. The decoction is a more convenient form for administration. It may be prepared by boiling half an ounce of the dried root in a pint and a half of water to a pint, of which from one to two fluidounces (30–60 C.c.) may be given twice or thrice daily, or more frequently. The watery extract, in doses of three or four grains (0·20–0·26 Gm.), three times a day, will generally act on the bowels.

APOMORPHINÆ HYDROCHLORAS. U. S. (Br.) Apomorphine Hydrochlorate.

$C_{17}H_{17}NO_2$, HCl; 302·79. (ĂP-Ǫ-MÖR-PHĪ'NÆ HŸ-DRǪ-ȻHLŌRĂS.) $C_{17}H_{17}NO_2$, HCl; 303·4.

"The hydrochlorate of an artificial alkaloid prepared from morphine or codeine. It should be kept in small, dark amber-colored vials." *U. S.* "The hydrochloride, $C_{17}H_{17}NO_2$,HCl, of an alkaloid obtained by heating morphine hydrochloride or codeine hydrochloride in sealed tubes with hydrochloric acid." *Br.*

Apomorphinæ Hydrochloridum, *Br.*, Apomorphine Hydrochloride; Chlorhydrate d'Apomorphine, *Fr.;* Apomorphinum Hydrochloricum, *G.;* Hydrochlorate of Apomorphine.

Apomorphine was discovered by Dr. Matthiessen and Mr. C. A. Wright. It is prepared by heating morphine in a closed tube with a great excess of hydrochloric acid for two or three hours to the temperature of 140° to 150° C. The contents of the tube are then dissolved in water, an excess of sodium bicarbonate added, and the precipitate exhausted with ether or chloroform. On the addition to a solution of a very small quantity of hydrochloric acid, crystals of apomorphine chloride form. The process is one of dehydration; the morphine parting with one molecule of water, the formula of apomorphine being $C_{17}H_{17}NO_2$. Apomorphine may also be made by the action of hydrochloric acid upon codeine, and it is affirmed that the best method in practice is that of E. Mayer, in which morphine is treated with a solution of zinc chloride, at 120° C. (*Berichte d. Deutsch. Chem. Gesell.*, Berlin, 1871, iv. 121.) Codeine, $C_{18}H_{21}NO_3$, when treated with hydrochloric acid, yields first $C_{18}H_{20}ClNO_2$, and then splits off methyl chloride, CH_3Cl, and leaves apomorphine, $C_{17}H_{17}NO_2$.

Properties. Apomorphine Hydrochlorate is usually in "minute, grayish-white, shining, acicular crystals, without odor, having a faintly bitter taste, and acquiring a greenish tint upon exposure to light and air. Soluble, at 15° C. (59° F.), in about 45 parts of water, and about 45 parts of alcohol; very little soluble in ether or chloroform. When heated to near 100° C. (212° F.), the salt is decomposed, rapidly if in solution, slowly when dry. At 270° C. (518° F.) it fuses to a black mass, and, when ignited, it is consumed without leaving a residue. The salt is neutral to litmus paper. The crystals are colored blood-red to orange by nitric acid, tran-

siently violet to light brown by sulphuric acid, dark purple to orange by a mixture of these acids. On shaking a few C.c. of the saturated, aqueous solution of the salt with a few small particles of manganese dioxide, the liquid acquires a green color, which is turned reddish-brown by adding some crystals of oxalic acid. If the oxalic acid be added to the solution first, and then a few small particles of manganese dioxide, the liquid will, upon agitation, assume a deep brownish-red color. Silver nitrate test-solution added to the aqueous solution of the salt throws down a white precipitate, insoluble in nitric acid, soon turning black by reduction to metallic silver, or instantly reduced by addition of ammonia water. Addition of sodium bicarbonate solution to the aqueous solution throws down the white amorphous alkaloid, which soon turns green on exposure to air, and imparts a violet or blue color to chloroform, in which it is very soluble (difference from *morphine*). If the salt impart, at once, an emerald-green color to 100 parts of water on being shaken with it a few times in a test-tube, it should be rejected." *U. S.* "Small, grayish-white, shining, acicular crystals, turning green on exposure to light and air, inodorous. Soluble in 50 parts of *water* and more soluble in *alcohol* (90 per cent.), the solutions being decomposed with production of a green color when they are boiled. Neutral or very feebly acid to *solution of litmus*. From solutions, *solution of sodium bicarbonate* throws down a precipitate which becomes green on standing and then forms a solution which is purple with *ether*, violet with *chloroform*, and bluish green with *alcohol* (90 per cent.). With dilute *test-solution of ferric chloride* it gives a deep red, and with *nitric acid* a blood-red coloration. If the salt impart an emerald-green color to 100 parts of *water*, after shaking the mixture, it should be rejected." *Br.* The alkaloid is colored dark red by nitric acid and rose-red by ferric chloride, changing to violet, and finally black, on exposure. The aqueous and alcoholic solutions are at first colorless, but change rapidly to greenish, finally becoming deep emerald-green in color. This change in color has been attributed to oxidation, and it has been noticed that the solution on standing loses its power: for this reason it is best not to keep the solution, but to make it as wanted. Mr. C. Bernbeck affirms that the change in the solution to a green color may be prevented by the addition of a small quantity of hydrochloric acid, the green coloration being due to ammonia. (*Pharm. Zeitung*, 1885.) According to Max Quehl and H. Koehler, apomorphine is precipitated from its solutions greenish by tannic acid, lemon-yellow by picric acid, bluish white, and turning to sap-green on boiling, by copper sulphate, purplish by gold chloride, white, turning to blackish violet on boiling, by potassium ferricyanide, blood-red by iodine in solution of potassium iodide, the precipitate disappearing on boiling, white and curdy by potassium sulphocyanate. (*A. J. P.*, 1873, p. 166.) With potassium bichromate and concentrated sulphuric acid it turns a dark red; with the potassium salt alone, a deep yellow-orange; with neutral iron chloride, an amethyst color.

Medical Properties and Uses. Apomorphine hydrochlorate was first brought forward as a prompt and safe emetic by Dr. Gee. It has the great advantages of smallness of dose and freedom from irritating properties, so that it can be used hypodermically. When from $\frac{1}{15}$ to $\frac{1}{10}$ of a grain (0·004–0·006 Gm.) of it is injected under the skin of a man, in from 5 to 20 minutes free emesis usually occurs; the dose may be repeated at intervals if necessary. The effects upon the general system are usually not marked; but in some cases very alarming syncopal symptoms have been produced, and death is said to have resulted from $\frac{1}{15}$ of a grain (0·004 Gm.) in a feeble adult worn out with chronic bronchitis and emphysema. (*Med. Rec.*, 1877, p. 664.) According to Harnack, young children bear the remedy very badly. Apomorphine hydrochlorate is a valuable sedative expectorant, useful whenever it is desired to produce relaxation and increase of secretion. As an emetic, it has been employed in *narcotic poisoning*, to dislodge *foreign bodies from the œsophagus*, in *suffocative catarrh*, etc. Very alarming symptoms have followed the use of a solution which has undergone change, and fresh solutions only should be administered. Under no circumstances should more than $\frac{1}{4}$ of a grain (0.016 Gm.) be given at a dose; the expectorant dose is from $\frac{1}{6}$ to $\frac{1}{12}$ of a grain (0·004 to 0·005 Gm.), administered every two or three hours, by the mouth.

AQUÆ. Medicated Waters.

(Ā'QUÆ—ā'kwē.)

Aquæ Destillatæ; Distilled Waters, *E.*: Eaux distillées, Hydrolats, *Fr.*: Destillirte Wässer, *G.*

Under this head are included, in the U. S. Pharmacopœia, all preparations consisting of water holding volatile or gaseous substances in solution, many of which were formerly obtained by distillation, and some of which still continue to be so. They include the preparations for-

merly specially designated as "Distilled Waters," having been made by distilling water from plants or parts of plants containing volatile oil.

The Distilled Waters, as thus defined, hold a much more prominent position in the pharmacy of Europe, particularly of continental Europe, than in that of the United States; and a great deal of thought and elaborate investigation has been bestowed there upon the various conditions calculated to furnish the best products in the most convenient method. It would be doing injustice to the subject not to give it a distinct consideration in a work like the present.

Many vegetables impart to water distilled from them their peculiar flavor, and more or less of their medical properties. The Distilled Waters chiefly used are those prepared from aromatic plants, the volatile oils of which rise with the aqueous vapor and are condensed with it in the receiver. But as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed chiefly as pleasant vehicles or corrigents of other medicines.

In the preparation of the Distilled Waters, dried plants are sometimes used, because the fresh are not to be had at all seasons; but the latter, at least in the instance of herbs and flowers, should be preferred if attainable. Flowers which lose their odor by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state afford Distilled Waters of delicate flavor. Some pharmacists prefer to employ the salted flowers in certain instances, believing that the waters distilled from them keep better than when prepared from the fresh flowers. Mr. C. R. Tichborne has discovered a method of preserving flowers which is said to answer even better than the use of salt. It consists simply in immersing the fresh flowers in glycerin, which preserves them with all their aromatic properties wholly unimpaired. The flowers, as of the elder, rose, and orange, should be gathered after full expansion, and packed firmly in wide-mouthed bottles or jars, but without crushing them. The glycerin is then to be poured on until it covers them, and the vessel closed. Mr. Tichborne has kept flowers in this way for two years, and at the end of that time procured from them distilled waters, of which the perfume has equalled that of the waters prepared from recent flowers. It is not necessary that the glycerin should be perfectly pure; but it should be without smell. (*P. J. Tr.*, 2d ser., vii. 135.)

The idea at one time prevailed, to a considerable extent, that Waters kept better distilled from dried herbs than from fresh; and the opinion was true in regard to those prepared with the defective alembics of former times and by a naked fire; but experiment has sufficiently established the fact that, with a suitable apparatus, and a regular heat, the fresh herbs yield products which, while they have a more agreeable odor of the plant, keep quite as well as those from dried herbs.

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previous to the operation. The quantity of materials should not bear too large a proportion to the capacity of the alembic, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state till the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the vegetable matter; lest a portion of the latter, coming in contact with the sides of the vessel, might be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously, or carried too far, a slimy matter is apt to form, which adheres to the sides of the still above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil-bath, regulated by a thermometer, or of a bath of solution of calcium chloride, by which any temperature may be obtained between 100° C. (212° F.) and 132·2° C. (270° F.), according to the strength of the solution; or, when the process is conducted upon a large scale, by means of steam introduced under pressure into a space around the still. To prevent the disagreeable effects of charring, and the excessive empyreumatic odor frequently noticed in distilled waters, caused by the solid contents of the still coming into direct contact with the heated bottom, we have devised an expedient which prevents the herb from touching the bottom and yet permits the water and steam to have free access to all parts of it. (See Pharmaceutical Still, under *Extracta.*) A hemispherical No. 12 sieve of copper with a handle and loosely-fitting lid is filled with the herb and placed in the water in the still. If the bottom of the still be flat or nearly so, the rounded bottom of the cage must have a very slight point of contact, and thus charring will be pre-

vented. A convenient mode of applying heat by steam is by means of a coil of leaden tube placed in the bottom of the still, having one end connected with a boiler, and the other passing out beneath or at the side, and furnished with a stop-cock, by which the pressure may be increased or the condensed water drawn off at will. If any volatile oil float upon the surface of the Distilled Water, it may be separated.*

From a series of experiments made in Paris in reference to the best mode of applying heat, it was concluded that as regards the great majority of aromatics the direct application of steam was preferable, because the Distilled Waters prepared by means of it have a freshness of aroma that is wanting in the others, are always free from the odor of the still, are much more limpid, are less apt to deposit mucilaginous matter, and keep better; but that exceptions to the general rule are afforded by bitter almonds, cherry-laurel leaves, mustard, and horse-radish, in all of which the oil does not pre-exist in the plant, but is formed upon contact with water; by woods, barks, and roots, the tissue of which cannot be sufficiently penetrated by steam; and by roses. (*Journ. de Pharm.*, Mai, 1861, p. 364.) Later experiments have led to the conclusion that even these substances are most advantageously treated by distillation with steam, and that, in fact, there is no exception to the rule.

But, however carefully the process may be conducted, the Distilled Waters prepared from plants always have at first an unpleasant smoky odor. They may be freed from this by exposure for a short time to the air before being enclosed in well-stopped bottles, in which they should be preserved. When long kept, a viscid ropy matter is apt to form in them, and they become sour. This result has been ascribed to other principles, which rise with the oil in distillation and promote its decomposition. To prevent this decomposition, rectified spirit is sometimes added to the water employed in its distillation. But this addition is inadequate, and is in fact injurious, as the alcohol by long exposure to the air undergoes the acetous fermentation. A better plan is to redistil the Waters. When thus purified, it is said that they may be kept for several years unchanged.

Robiquet considered the mucosity which forms in Distilled Waters to be the result of a vegetative process, for which the presence of air is essential. He has found that so long as the water is covered with a layer of essential oil it undergoes no change, but that the oil is gradually altered by exposure to the air, and, as soon as it disappears, the water begins to be decomposed. He states that camphor exercises the same preservative influence over the Distilled Waters by resisting the vegetation, and that those in which the odor of camphor is developed keep better on that account. Finally, he has observed that the more Distilled Water is charged with volatile oil, the more abundant is the mucosity when it has begun to form. Robiquet unites with Henry and Guibourt, and with Virey, in recommending that all these waters, when intended to be kept for a considerable time, should be introduced, immediately after distillation, into bottles of a size proportionate to the probable consumption of the water when brought into use; and that the bottles should be quite filled, and then sealed or otherwise well stopped, so as entirely to exclude the air. It is best that they should be small, and be closed with well-fitting glass stoppers. Thus treated, the Waters may be preserved without change for many years. (*Journ. de Pharm.*, xxi. 402.) This view is opposed to the experience of large producers of Distilled Waters; we have seen at Grasse hundreds of carboys stored away, containing distilled rose and orange flower waters, not only uncorked, but having only a thin piece of muslin laid over the lips to exclude dust. We were informed by the distillers that the waters retained their qualities unimpaired for years far better when treated in this way than if stoppered tightly. We have frequently noticed microscopic plants belonging to the *Confervoideæ* in the Distilled Waters contained in shop bottles standing on the shelves in the dispensing room, and if it be desired to keep Distilled Waters, the only sure way is to destroy the spores and prevent the admission of fresh ones by placing the bottles filled to the lip with the Distilled Water into a bath of boiling water, and, when thoroughly sterilized by heating, corking and sealing.†

* This direction is generally given; but, in a communication to the Pharmaceutical Society of Great Britain, Haselden recommends the excess of oil to be well shaken with the water, and the whole to be transferred to the stock vessel, where it may be allowed to rest, and the oil to separate. He thinks the water keeps better when thus treated; and the full strength is always insured. The stock vessel he prefers made of stoneware, and furnished with a tap placed two inches from the bottom, whereby the water may be drawn off clear when wanted for the ordinary shop bottles; the oil rising to the top, or sinking to the bottom, according to its sp. gr. (*P. J. Tr.*, xvi. 14, 15.)

† It is of some importance to know the proportion which the aromatic submitted to distillation ought to bear to the amount of Distilled Water obtained. The following statement upon this point, based upon experiments, is contained in the *Journ. de Pharm.* (Mai, 1861, p. 367). Fresh aromatic plants requiring one part of the plant for one

Another mode of preparing the Distilled Waters is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed in the British Pharmacopœia in several instances. It is said to afford a more permanent product than the preceding, but does not always preserve the flavor of the plant.

In relation to most of the aromatic waters, the U. S. Pharmacopœia formerly directed that water should be impregnated with the volatile oil by trituration with magnesium carbonate, and subsequently filtered. This was by far the most simple and easy process. The resulting solution is nearly pure and permanent, and is perfectly transparent, the magnesium carbonate being separated by the filtration. Magnesium carbonate is preferable to the pure earth, as the latter sometimes gives a brownish color to the liquid, and requires to be used in larger proportion. But both these substances are dissolved in minute quantities, and are apt to occasion a slight flocculent precipitate. They may also possibly prove injurious by decomposing certain substances given in very small doses, as salts of the alkaloids, mercury bichloride, and silver nitrate. The object of the magnesia or its carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. Precipitated calcium phosphate has been used as a substitute for magnesium carbonate, but this has been shown to be slightly soluble in water; notwithstanding this objection, its use is sanctioned by the U. S. Pharmacopœia of 1890. W. S. Thompson, of Washington, D.C., suggested the use of absorbent cotton as being free from all of these objections, and his views were substantially adopted by the Committee of Revision of the Pharmacopœia of 1880. Mr. E. V. Zoeller proposes to use a hand cotton-card to aid in pulling the filaments of cotton apart when a large quantity of medicated water is needed. (*New Rem.*, 1883, p. 56.) Experience has shown, however, that the use of an insoluble powder to effect the minute division of the particles of oil, so as to present a large surface to the solvent, is a more practical and convenient method of making medicated waters. According to Mr. Robert Warington, this object may be better accomplished by porcelain clay, finely-powdered glass or pumice-stone, which are wholly insoluble; and the London College employed finely-powdered silica for the purpose. Talcum or soapstone in powder, purified by washing with diluted hydrochloric acid, has been adopted by the Committee on National Formulary (1888). (See *Talcum Purificatum*, PART II.; also paper recommending it by Prof. Curtman, *Proc. A. P. A.*, 1887.) A very good way to make medicated waters when a volatile oil is directed, is that proposed by Percival, which is to heat the water required, pour it in a bottle and add the oil, cork tightly, shake occasionally until cool, then pour off and filter; this secures a medicated water free from foreign substances, and a saturated solution; most oils being more soluble in hot than in cold water. The Dublin College prepared its Waters by agitating an alcoholic solution of the oil with distilled water, and filtering. They consequently contained alcohol, and were liable to the objection, already mentioned, against the medicated waters thus impregnated. They were, besides, feeble in the properties of their respective oils. In the preparation of the aromatic waters by these processes, it is very important that the waters should be pure. The presence of a sulphate causes a decomposition of the oil, resulting in the production of hydrogen sulphide and a carbonate; and the aromatic properties are quite lost. (See *A. J. P.*, xix. 303.) Hence the propriety of the official direction to employ distilled water.*

The Distilled Waters are liable to contain various metallic impurities, derived from the vessels in which they are prepared or preserved. The metallic salts which have been found in them are those of iron, zinc, copper, and lead. With potassium ferrocyanide, iron will give a blue color, zinc and lead white precipitates, and copper a rose color followed by chestnut brown. Sodium sulphide causes with the salts of iron, copper, and lead, a brown discoloration more or less deep, followed by precipitates varying from brown to black; with those of zinc a white precipitate. The Distilled Waters may be freed from these impurities by animal charcoal, previously well purified. The charcoal should be strongly shaken, eight or ten times in the course of a day, with the impure Water, which should then be allowed to rest, and the

of product, wormwood, black cherry, scurvy-grass, hyssop, cherry-laurel, lavender, balm, mint, peach-leaves, roses, and sage;—fresh and dry aromatic plants requiring one part of the plant for two of product, bitter almonds, orange-flowers, melilot, horseradish, elder, and tansy;—dry and very aromatic plants requiring one part of the plant for four of product, angelica, green anise, juniper berries, chamomile, canella, cascarilla, fennel, sassafras, linden flowers, and valerian.

* Mr. Haselden prefers the process of distillation from the aromatic itself in the instances of dill, caraway, fennel, cinnamon, and pimento, which are not apt to afford to the distilled water such matter as may cause it to become sour; but he prefers trituration for peppermint, spearmint, and pennyroyal waters. He advises, however, that these waters should not be filtered, but prepared in quantity, allowed to settle, and drawn off as wanted. (*P. J. Tr.*, xvi. 14, 15.)

next day be filtered. Five grains of the charcoal will be sufficient for a gallon of the Distilled Water. (*Journ. de Pharm.*, Nov. 1862, p. 416.) The volatile oils may be recovered from the Waters containing them, or at least may be transferred to a spirituous menstruum, by mixing olive oil with the water, adding a little solution of potassa so as to form a soap, and a consequent emulsion with the liquid, and then neutralizing by an acid. The fixed oil will rise to the surface, bringing the volatile oil along with it. The latter may then be separated from the former by agitation with alcohol. (T. P. Groves, *P. J. Tr.*, Feb. 1864.)

AQUA. U. S. Water.

"Natural water in its purest attainable state." *U. S.*

Aqua communis, *P. G.;* **Ὕδωρ**, *Gr.;* **Eau**, *Fr.;* **Wasser**, *G.;* **Acqua**, *It.;* **Agua**, *Sp.*

Water has always been included in the U. S. Pharmacopœia, on account of its great importance as a medical and pharmaceutical agent. It was not admitted into the official lists of the British Pharmacopœias until 1839, when it was first recognized by the Edinburgh College, but it was dropped at the last revision of the British Pharmacopœia. It is more or less concerned in almost all the changes which take place in inorganic matter, and is essential to the growth and existence of living beings, whether animal or vegetable. In treating of a substance of such diversified agency, our limits will allow of a sketch only of its properties and modifications. We shall speak of it under the several heads of *pure water, common water*, and *mineral waters.*

Pure Water. Water, in a pure state, is a transparent liquid, without color, taste, or smell. Its sp. gr. is assumed to be unity, and forms the term of comparison for that of solids and liquids. A cubic inch of it, at the temp. of 15·5° C. (60° F.), weighs very nearly 252·5 grains. In the metric system the weight of 1 C.c. of distilled water taken at 4° C. (39·2° F.) is made equal to 1 gramme, the unit of weight in this system. It is compressible to a small extent, as was proved first by Canton, and afterwards, in an incontestable manner, by Perkins. Reduced in temp. to 0° C. (32° F.), it becomes a solid or ice, with the sp. gr. 0·9175 (Dufour, *Comptes-Rendus*, Juin, 1860); and raised to 100° C. (212° F.), an elastic fluid called steam. In the latter state its bulk is increased nearly 1700-fold, and its sp. gr. so far lessened as not to be much more than half that of atmospheric air. At the temp. of 4° C., or 39.2° F., its density is at the maximum; and consequently, setting out from that point, it is increased in bulk by being either heated or cooled. It has the power of dissolving more or less of all gases, including common air, the constituents of which are always present in natural water. It uniformly exists in the atmosphere, in the form of invisible vapor.

Water consists of two atoms of hydrogen and one of oxygen; or, in volumes, of two volumes of hydrogen and one volume of oxygen condensed into two volumes of aqueous vapor or steam. On these data, it is easy to calculate the sp. gr. of steam; which will be 0·0693 (sp. gr. of hydrogen) + 0·5528 (half the sp. gr. of oxygen) = 0·6221.

Common Water. By reason of its extensive solvent powers, water, in its natural state, must be more or less contaminated with foreign matter. Thus, it becomes variously impregnated, according to the nature of the strata through which it percolates. When the foreign substances present are in so small an amount as not materially to alter its taste and other sensible qualities, it constitutes the different varieties of *common water.*

There are almost innumerable shades of difference in common water, as obtained from different localities and sources; but all its varieties may be conveniently arranged under the two heads of soft and hard. A *soft water* is one which contains but inconsiderable impurities, and which, when used in washing, forms a lather with soap. By a *hard water* is understood a variety of water which contains calcareous or magnesian salts, or other impurities, through which it curdles soap, and is unfit for domestic purposes. Tincture of soap is a convenient test for ascertaining the quality of water. In distilled water it produces no effect; in soft water, only a slight opalescence; but in hard water, a milky appearance. The milkiness is due to the formation of an insoluble compound between the fatty acids of the soap and the lime or magnesia of the foreign salt.

The most usual foreign substances in common water, besides oxygen and nitrogen, and matters held in a state of mechanical suspension, are carbonic acid, calcium sulphate and carbonate, and sodium chloride (common salt). Carbonic acid is detected by lime water, which produces a precipitate before the water is boiled, but not afterwards, as ebullition drives off

this acid. The presence of calcium sulphate is shown by precipitates being produced by barium nitrate, and, after ebullition, by ammonium oxalate. The former test shows the presence of sulphuric acid, and the latter, after boiling the water, indicates lime not held in solution by carbonic acid. Calcium carbonate, when held in solution by an excess of carbonic acid, may be detected by boiling the water, which causes it to precipitate; but even after ebullition and filtration the water will retain enough calcium carbonate to give a precipitate with lead acetate, calcium carbonate being itself to a minute extent soluble in water. Silver nitrate will produce a precipitate, if any soluble chloride be present; and, ordinarily, the one present may be assumed to be common salt. Arsenic in minute quantity has been found in water used as drink. At Whitbeck, in Cumberland, England, the inhabitants employ, both as drink and for culinary purposes, a water holding enough arsenic in solution to be quite sensible to tests, without any known injurious consequence. (*Chem. News*, 1860, p. 128.)

Dr. Clark has proposed to purify hard water, when the hardness arises from calcium bicarbonate, by a process which he calls *liming*. This consists in adding to the water sufficient lime water to convert the bicarbonate into the very sparingly soluble carbonate. This procedure renders the water soft, and gets rid of all the lime, except that in the minute portion of carbonate dissolved. The merit of this process consists chiefly, not in the removal of lime, but in preventing the formation of organic matters, principally confervæ, the decomposition of which renders the water offensive and unwholesome. Dr. Clark's process has been for some time in successful operation on the water obtained by boring, at the Plumstead water-works, near Woolwich. (*P. J. Tr.*, June, 1856.) River water containing the usual amount of calcareous matter, if allowed to stagnate in open reservoirs, in the summer, will become contaminated with myriads of microscopic plants and animals. This change is prevented, according to Dr. Clark, by his peculiar treatment, which deprives the living organisms of the nutriment derived from loosely combined carbonic acid.

The oxygen and nitrogen present in natural waters are not usually in the same proportion as in atmospheric air; the oxygen in atmospheric air amounting to about 20 per cent. in volume, while the usual gaseous mixture expelled from fresh water by boiling contains 32 per cent. (See table on page 196.)

Common water is also divided into varieties according to its source. Thus, we have rain, snow, spring, river, well, lake, and marsh water.

Rain and *snow water* are the purest kinds of natural water. Rain water, to be obtained as pure as possible, must be collected in large vessels in the open fields, at a distance from houses, and some time after the rain has commenced falling; otherwise it will be contaminated with the dust which floats in the atmosphere, and with other impurities derived from roofs. The rain water of large cities contains nitrogenized organic matter, as shown by the odor produced by burning the residue left after the water has been evaporated.

Rain water ordinarily contains atmospheric air, and, according to Liebig, a little nitric acid, the amount of which is increased when the rain descends during a storm. M. Chabrier states as the result of his observations that rain water contains either nitrous or nitric acid, the one or the other predominating according to the condition of the weather; the nitrous acid being relatively in excess in mild weather, but the nitric when the rain is attended with tempestuous winds. (*Journ. de Pharm.*, Janv. 1872, p. 42.) According to an analysis, made by M. Martin, of rain water which fell at Marseilles during a violent storm, 1000 parts by weight contained 0·004 of chlorine and 0·003 of ammonia. Not a trace of iodine or of nitric acid was discovered. Boussingault has ascertained that the rain which falls in towns contains considerably more ammonia than that which falls in the country. Thus the rain of Paris was found by him to contain three or four parts of ammonia per million; while that collected in a mountainous region contained about four-fifths of one part only in a million. The average results of Mr. J. B. Lawes and Dr. J. H. Gilbert give one part of ammonia to the million of rain water. Snow water has a peculiar taste, which was supposed to depend on the presence of air more oxygenated than that of the atmosphere; but in point of fact it contains no air, and this accounts for its vapid taste. Rain and snow water are sufficiently pure for most chemical operations.

Spring water (*aqua fontana*) depends entirely for its quality on the strata through which it flows; being purest when it passes through sand or gravel, or where the prevailing rock formation is granitic. On the contrary, where the formation is limestone, the water will, because of the carbonic acid gas dissolved in it, take up the lime carbonate and become what is called

a *hard water*. It almost always contains a trace of common salt, and generally other impurities, which vary according to the locality of the spring.

River water (*aqua fluvialis*) is, generally speaking, less impregnated with saline matter than spring water, because made up in considerable part of rains; while its volume bears a larger proportion to the surface of its bed. It is, however, much more apt to have mechanically suspended in it insoluble matters, of an earthy nature, like clay and silt, which impair its transparency. It is frequently rendered more sightly by being run through porous stone, carbon, or sand filter. The coarse particles are by this filtration removed; but any sewage or other very finely divided organic material is not removed, so that such clean filtered water may be a very deadly poison. Water may be purified for manufacturing purposes by what is termed the alum process,—*i.e.*, by adding 2 grains of alum to a gallon of water, and permitting the impurities to subside for 48 hours. (*Chem. News*, July 23, 1886.)

Well water, like that from springs, is liable to contain various impurities. As a rule, the purity of the water of a well will be in proportion to its depth and the constancy with which it is used. Well water in large cities always contains a large amount of impurity, both organic and inorganic, the result of sewage contamination. Dr. R. D. Thomson found 147·6 grs., per Imperial gallon, of impurity in a well in London. (*P. J. Tr.*, 1856, p. 27.) The presence of nitrates in water prevents the formation of organic beings, even after it has been long kept. *Artesian* or *overflowing wells*, from their great depth, generally afford a pure water.

Lake water cannot be characterized as having any invariable qualities. The water of most of the lakes in the United States is pure and wholesome.

Marsh water is generally stagnant, and contains vegetable remains undergoing decomposition. It is unwholesome, and ought never to be used internally.

All water which is exposed to the air dissolves a quantity of oxygen, nitrogen, and carbon dioxide, in obedience to the laws of gaseous absorption. It is indeed upon this dissolved oxygen that the life of water-breathing animals depends. In every pure water the proportion between the dissolved nitrogen and oxygen is found to be constant, and it is represented by the following numbers:—oxygen 34·91, and nitrogen 65·09 per cent.: 1000 C.c. of pure water, such as rain water, when saturated dissolves 17·95 C.c. of air. If the water be rendered impure by the introduction of organic matter undergoing oxidation, the proportion between the dissolved oxygen and nitrogen becomes different, owing to the oxygen having been partly or wholly used for the oxidation of this material. This is clearly shown in the following analysis made by Miller of the dissolved gases contained in Thames water collected at various points above and below London.

	Thames water taken at					
	Kingston.	Hammer-smith.	Somerset House.	Greenwich.	Woolwich.	Erith.
Total volume of gas per liter	C.c. 52·7	C.c. . . .	C.c. 62·9	C.c. 71·25	C.c. 63·05	C.c. 74·3
Carbon dioxide	30·3	. . .	45·2	55·6	48·3	57·0
Oxygen	7·4	4·1	1·5	0·25	0·25	1·8
Nitrogen	15·0	15·1	16·2	15·4	14·5	15·5
Ratio of oxygen to nitrogen	1 : 2	1 : 3·7	1 : 10·5	1 : 60	1 : 52	1 : 8·1

This table shows that whereas the pure water at Kingston contains the normal quantity of dissolved oxygen, the ratio of nitrogen to oxygen increases at a very rapid rate as the river water becomes contaminated with London sewage, but that this ratio again shows signs of a return to the normal at Erith. Moreover, carbon dioxide should not constitute more than from 8 to 10 per cent. of the dissolved gases in a pure water, but in these cases it has become 60 per cent. or over of the gases as obtained from the water for analysis.

Hence it is clear that an analysis of the gases dissolved in water may prove of much help in ascertaining whether the water is pure or whether it has been contaminated with putrescent organic matter. Indeed, Miller concludes that whenever the proportion between dissolved oxygen and nitrogen falls to less than 1 to 2 the water is unfit for drinking purposes. (Roscoe and Schorlemmer, *Treatise on Chem.*, i. 245.)

The second class of dissolved impurities are inorganic salts, even rain water washing some

of these out of the atmosphere. It invariably contains ammoniacal salts, sodium chloride, and various organic germs. In towns the rain water also contains a larger proportion of nitrates than that falling in the country. It is, however, the spring waters especially which contain the largest amount of mineral matter in solution. The salts which most commonly occur in solution in spring water are: (1) The calcium, magnesium, iron, and manganese carbonates, dissolved in an excess of carbonic acid. (2) The calcium and magnesium sulphates. (3) Alkaline carbonates, chlorides, sulphates, nitrates, or silicates.

Spring waters which issue from considerable depths, or which originate in volcanic districts, are always hotter than the mean annual temperature of the locality where they come to the surface.

The term *Aqua*, in the United States Pharmacopœia, may be considered as designating any natural water of good quality which answers well for cooking and does not curdle soap. "A colorless, limpid liquid, without odor or taste at ordinary temperatures, and remaining odorless while being heated to boiling. Water should be perfectly neutral to litmus paper, and its transparency should not be affected, nor should any color be imparted to it, by hydrogen sulphide test-solution, or ammonium sulphide test-solution (absence of *metallic impurities*). It should also remain unaffected by mercuric chloride test-solution (limit of *ammonia*). On evaporating 1000 C.c. of Water on a water-bath, it should not leave a residue weighing more than 0·5 Gm. (limit of *soluble salts*), and this residue, when ignited, should not carbonize, nor evolve *ammoniacal* or *acid* vapors. If 200 C.c. of water be acidulated with hydrochloric acid and heated to boiling, and 0·5 C.c. of barium chloride test-solution added, the liquid, cooled and filtered, should give no further precipitate on the addition of a few drops of barium chloride test-solution, even on standing (limit of *sulphates*). If 200 C.c. of Water be acidulated with nitric acid, and 0·5 C.c. of silver nitrate decinormal volumetric solution be added, the filtered liquid should not be affected by the subsequent addition of a few drops of silver nitrate test-solution (limit of *chlorides*). If 5 C.c. of Water mixed with a few drops of diphenylamine test-solution be carefully poured upon about 2 C.c. of sulphuric acid, free from nitrose, contained in a test-tube, so as to form a separate layer, no blue color should be formed at the line of contact of the two liquids (limit of *nitrates*). If 100 C.c. of Water be acidulated with diluted sulphuric acid free from nitrose, and a few drops of zinc-iodide-starch test-solution, subsequently added, the liquid should not at once assume a blue or violet color (absence of *nitrites*). On heating 100 C.c. of Water, acidulated with 10 C.c. of diluted sulphuric acid, to boiling, and subsequently adding 0·5 C.c. of potassium permanganate decinormal volumetric solution, the color of the liquid should not be completely destroyed by boiling it for ten minutes (limit of *organic* or *other oxidizable matters*)." *U. S.*

The British Pharmacopœia no longer includes "Aqua;" it recognizes "Aqua Destillata," and gives appropriate tests. (See page 212.)

Water should never be kept in leaden cisterns, on account of the risk of its dissolving a small portion of lead. This risk is greater in proportion to the softness and purity of the water; for it is found that the presence of a minute proportion of saline matter, as for example of calcium sulphate, protects the water from the slightest metallic impregnation. The chlorides are not protective, as they give rise to lead chloride, which is slightly soluble. The protection has been ascribed to an insoluble film on the surface of the lead, formed by the decomposition of the saline matter. Upon this principle is based a plan of protection by Dr. Schwartz, of Breslau, who proposes to fill leaden pipes through which water is conducted with a strong solution of an alkaline sulphide, which forms a perfectly insoluble coating of lead sulphide (*sulphuret*), said to be quite impermeable by the water afterwards introduced. (*Chem. News*, Sept. 26, 1863, p. 157.) A coating of zinc has been employed for protecting the surface of iron pipes and reservoirs against the action of water, but has failed. Experiment has shown that the water becomes impregnated with the salts of both metals. (*Ibid.*, April 5, 1862, p. 188.)* Mr. A. Wynter Blyth proposes a new and simple test for lead in drinking-water. A solution of cochineal is made by boiling cochineal in water, filtering, and adding a little alcohol to preserve it. A few drops of this solution are added to the water, which, if

* Experiments by M. Roux, pharmaceutist of the marine at Rochefort, made by order of the naval authorities, have satisfactorily shown that reservoirs of iron coated with zinc are attacked with great facility by water contained in them, which becomes more or less impregnated with both metals in the state of oxides and salts, and especially with those of zinc to such a degree as to render such vessels improper as recipients of water for drinking. Of the different kinds of water tried, distilled water deprived as far as possible of atmospheric air produced least effect; next in degree of action was spring water; still more energetic was distilled water containing carbonic acid furnished by the earthy bicarbonates of the water submitted to distillation; and more powerful than all was river water containing common salt. (*Journ. de Pharm. et Chim.*, 4e sér., i. 99.)

acid, must be rendered neutral by a trace of alkali; if lead be present, even in the proportion of one-tenth of a grain in a gallon of water, a mauve-blue color will develop, its depth depending upon the quantity of lead in the water. (*Amer. Drug.*, 1884, p. 93, from *The Analyst.*)

A very important class of dissolved impurities is made up of organic compounds. This organic matter may be derived from a vegetable source, such as leaf-mould and the decomposition products of wood, in which case it is practically harmless, or it may be derived from animal sources, in which case it almost always proves a serious impurity.

The careful observations of students of public health leave no doubt that a number of epidemic diseases, especially cholera and typhoid fever, are often contracted and spread by means of drinking-water contaminated with germs of disease from excreta and general sewage. This impure water may be clear and may have filtered through considerable distances of soil, and yet may contain these poisonous germs. Now, nitrogen is one of the characteristic constituents of animal matter as contrasted with vegetable matter, relatively few forms of which contain it, and those are of a character not likely to be found in natural waters. Hence, if water should be impregnated with animal matter, this would be indicated by the presence of nitrogen in solution, either in the form of albumen or albuminous matter, if the animal matter in the water is still unchanged, or, if the animal matter has undergone oxidation, in the form of ammonia or nitrous or nitric acid.

There are, therefore, to be determined in the examination of a water with reference to this presence of organic nitrogenous matter, (1) the ammonia, (2) the unchanged albuminous matter, which, as it is changed into and determined as ammonia, is called "albuminoid ammonia," and (3) the nitrates and nitrites present.

The ammonia is first determined by distilling the water made alkaline with sodium carbonate as long as the distillate carries enough ammonia to be recognized by *Nessler's solution.** For this purpose the distillate is collected successively in volumes of 50 C.c. and the amount of ammonia in each of these separate distillates determined. The smallest quantity of ammonia will produce a yellow color, the tint of which is to be compared with that obtained from the Nessler solution treated with a standard sal ammoniac solution.

After the free ammonia has been distilled off, a solution of caustic soda and potassium permanganate is added and the distillation is continued. Another portion of ammonia now comes off, owing to the action of the permanganate on the nitrogenous organic matter. The amount of ammonia thus obtained is determined, and is tabulated as "albuminoid ammonia," because albumen is one of the bodies which is decomposed in this way. L. de Konnick found that the Nessler test in ammoniacal liquids does not produce the usual yellowish-brown precipitate, nor even a coloration, in the presence of alcohol. (*Amer. Drug.*, 1893, p. 386.)

Instead of this method, proposed by Wanklyn and Chapman, another process, described by Frankland and Armstrong, is often used. In this case, the water having been evaporated, the dry residue is submitted to an organic combustion analysis, which gives the "organic nitrogen" and the "organic carbon," and the ratio of these gives an indication as to the presence of albuminous matter rich in nitrogen. If the amount of albuminoid nitrogen indicated by either of these processes exceed 0·15 part for one million of water, the latter should be rejected as a drinking-water. In some large towns, however, the surface well waters have shown albuminoid nitrogen to the amount of 0·3 to 0·8 part per million. Such waters are little better than sewage. The free ammonia, moreover, should not exceed 0·08 part per million, or the water must be considered as containing sewage contamination.

The nitrates and nitrites present can be estimated in another portion of the water by reducing these acids to ammonia by means of the hydrogen evolved from aluminum or zinc-dust in presence of caustic alkalies.

The determination of chlorine is also frequently of great importance, for although mineral waters may be rich in chlorides, ordinary well waters or river waters, which are the chief sources of supply, will not contain much chlorine unless they have been contaminated. Both urine and sewage may contribute this chlorine, as they are highly charged with common salt. As a rule, it may be said that water containing more than two grains of chlorine per gallon must be looked upon with suspicion, unless some good reason for the presence of common salt can be assigned.

* This solution is prepared as follows. 35 Gm. of potassium iodide and 13 Gm. of mercuric chloride (corrosive sublimate) are dissolved in about 800 C.c. of hot water, and then a saturated solution of mercuric chloride is gradually added until the precipitate formed ceases to redissolve. 100 Gm. of caustic potash are then dissolved in the liquid, and the cold solution is diluted to one liter and is allowed to deposit any undissolved matter.

The following table shows the relative purity of the water-supply of several American cities, as determined by Prof. A. R. Leeds in 1881:

Parts in 100,000.	New York.	Brooklyn.	Jersey City.	Philadelphia.	Boston.	Washington.	Rochester.	Cincinnati.
Free ammonia	0·0027	0·00075	0·00475	0·001	0·01325	0·006	0·0114	0·0115
Albuminoid ammonia	0·027	0·00825	0·0427	0·018	0·0605	0·027	0·023	0·024
Oxygen required	0·81	0·413	0·95	0·46	1·77	0·600	0·790	0·860
Nitrites	None.	None.	None.	None.	None.	None.	None.	None.
Nitrates	0·8325	1·2025	0·9065	0·6845	1·2395	0·8325	0·629	0·740
Colorine	0·350	0·550	0·235	0·300	0·315	0·270	0·195	0·805

MINERAL WATERS. When natural spring waters are so far impregnated with foreign substances as to have a decided taste, and to operate in a peculiar manner upon the economy, they are called *mineral waters.* These are conveniently arranged under the heads of *carbonated*, *alkaline*, *sulphuretted*, *saline* (including *magnesian*, *chalybeate*, and *chlorinated*), and *silicious.*

1. *Carbonated waters* are cold, and are characterized by containing an excess of carbonic acid, which gives them a sparkling appearance, and the power of reddening litmus paper. These waters frequently contain calcium, magnesium, and iron carbonates, which are held in solution by the excess of carbonic acid. The waters of Selters, Spa, Apollinaris, and Pyrmont in Europe, and of the sweet springs in Virginia, belong to this class. For Artificial Carbonic Acid Water, see page 201.

2. *Alkaline waters* contain a large quantity of sodium bicarbonate, as well as common salt and Glauber's salt. These are sometimes warm, such as the springs at Ems and Vichy, but generally cold. Gettysburg spring water is of this class.

3. *Sulphuretted waters* are such as contain hydrogen sulphide, and are distinguished by the peculiar fetid smell of that gas, and by yielding a brown precipitate with the salts of lead or silver. Examples of this kind are the waters of Aix-la-Chapelle and Harrogate in Europe, and those of the white, red, and salt sulphur springs in Virginia.

4. *Saline waters* are those the predominant properties of which depend upon saline impregnation. The salts most usually present are sodium, calcium, and magnesium sulphates and carbonates, in which latter case the name *magnesian* is given to them; the presence of the chlorides of these alkalies giving the class *chlorinated* waters, which reach their maximum concentration in sea waters; whilst the presence of ferrous salts makes another class, the *chalybeate.* Among magnesian waters may be mentioned those of Friedrichshall, Hunyádi Janos, and Epsom; among chalybeate waters, those of Tunbridge and Brighton in England, of Pyrmont, Wiesbaden, and Spa on the continent, and of Bedford, Pittsburg, and Brandywine in the United States. Potassa is occasionally present, and lithia has been detected by Berzelius in Carlsbad and other salt springs of Germany, and is also found in some American spring waters. Cæsia and rubidia have also been detected in certain mineral waters, such as the Dürkheim and Baden-Baden waters, in the former of which these elements were first discovered by Bunsen. Bromine is found in the saline at Theodorshalle, in Germany, as also in the salt wells of Western Pennsylvania, Ohio, and West Virginia. The mineral springs at Saratoga contain a small proportion of iodine and bromine. The principal saline waters are those of Seidlitz in Bohemia, Cheltenham and Bath in England, and Harrodsburg and Saratoga in the United States.

5. *Silicious waters* are those in which the contents consist chiefly of alkaline silicates, such as the hot spring waters of Iceland and the geysers of Fire-hole Basin and Gardiner's River, Yellowstone National Park, U.S.

Sea Water. English Channel. In a thousand grains. Water 964·744 grs.; sodium chloride 27·059; potassium chloride 0·765; magnesium chloride 3·667; magnesium bromide 0·029; magnesium sulphate 2·296; calcium sulphate 1·407; calcium carbonate 0·033. Total 1000 grs. (*Schweitzer.*) The proportion of sodium chloride is from 36 to 37 parts in 1000 in the ocean, at a distance from land. Its amount is small in the interior of the Baltic. It is perceived that bromine is present in very minute amount; 100 pounds of sea water yielding only 3 grs. of this element. According to Balard, iodine exists in the water of the Mediterranean;

but it has not been detected in the water of the ocean, the bromine being supposed to mask its presence. Besides these ingredients, others are alleged to exist in minute proportion in sea water; as fluorine by Dr. G. Wilson; lead, copper, and silver by MM. Malaguti, Durocher, and Sarzeau; and iron and manganese by M. Uziglio. Anterior to Wilson's researches, Mr. Middleton and Prof. Silliman, jun., had inferred the existence of fluorine in sea water, from its presence in marine animals. The lead and copper above mentioned were found in certain fuci only; the silver in the sea water itself. The presence of silver in sea water has been rendered probable by Mr. F. Field, by a comparative analysis of the same copper sheathing, when new, and after having been on a vessel for many years. The old sheathing was always found to contain more silver than the new (*Chem. Gaz.*, March 2, 1857); and the observations of Mr. Field have been subsequently confirmed by others. Schweitzer's analysis gives a small proportion of calcium carbonate, but Bibra could not detect any. Dr. John Davy's examinations of sea water show that calcium carbonate does not exist at a great distance from land, except in very minute proportion, but becomes quite evident at a distance of from fifty to a hundred miles from coasts. Boric acid has been found by Mr. Veatch in the sea water on the coast of California. (See *A. J. P.*, 1860, p. 330.)*

Sea water, filtered, and charged with five times its volume of carbonic acid, forms, according to Pasquier, a gentle purgative, which keeps very well, and is not disagreeable to take. The dose is from half a pint to a pint.

By freezing, sea water is almost entirely freed from saline matter, the ice being nearly pure water. It is obvious that the unfrozen water contains much more than its ordinary proportion of salts; and this is one of the methods of concentrating this and other saline solutions.

Medical Properties of Water. Water is a remedy of great importance. When taken into the stomach, it acts by its temperature, by its bulk, and by being absorbed. When of the temperature of about 15·5° C. (60° F.), it gives no positive sensation either of heat or cold; between 15·5° C. (60° F.) and 7·2° C. (45° F.), it creates a cool sensation; and below 7·2° C. (45° F.), a decidedly cold one. Between 15·5° C. (60° F.) and 37·7° C. (100° F.), it relaxes the fibres of the stomach, and is apt to produce nausea, particularly if the effect of bulk be added to that of temperature. By its bulk and solvent powers, it allays irritation by diluting the acrid contents of the stomach and bowels, and favoring their final expulsion; and by its absorption, it promotes the secretion of urine and cutaneous transpiration.

Water externally applied as a bath is also an important remedy. It may act by its own specific effect as a liquid, or as a means of modifying the heat of the body. It acts in the latter way differently, according to the temperature at which it may be applied. When this is above 36·1° C. (97° F.), it constitutes the vapor or hot bath; when between 36·1° C. (97° F.) and 29·4° C. (85° F.), the warm bath; between 29·4° C. (85° F.) and 18·3° C. (65° F.), the tepid bath; and between 18·3° C. (65° F.) and 0° C. (32° F.), the cold bath.

The general action of the *vapor bath* is to accelerate the circulation, and produce profuse sweating. It acts locally on the skin, by softening and relaxing its texture. In stiffness of the joints, and in various diseases of the skin, it has often proved beneficial.

The *hot bath*, like the vapor bath, is decidedly stimulant. By its use the pulse becomes full and frequent, the veins turgid, the face flushed, the skin red, and the respiration quickened. If the temperature be high, and the constitution peculiar, its use is not without danger, as it is apt to produce a feeling of suffocation, violent throbbing in the temples, and vertigo with tendency to apoplexy. When it acts favorably, it produces profuse perspiration.

* The following analysis of sea water, taken at two leagues from Fécamp, on the coast of France, merits special notice from the care with which it was made, and the large quantity operated on. The sp. gr. was 1·026, at 57° F.

(*Journ. de Pharm. et de Chim.*, 4e sér., i. 381, 1865.)

The *warm bath*, though below the animal heat, nevertheless produces a sensation of warmth, as its temperature is above that of the surface. It diminishes the frequency of the pulse, renders the respiration slower, lessens the heat of the body, and relaxes the skin. It cannot, therefore, be deemed a stimulant. By relieving certain diseased actions and states, accompanied by morbid irritability, it often acts as a soothing remedy, producing a disposition to sleep.

The *tepid bath* is not calculated to have much modifying influence on the heat of the body. Its peculiar effects are to soften and cleanse the skin, and to promote insensible perspiration.

The *cold bath* acts differently according to its temperature and manner of application, and the condition of the system to which it is applied. When of low temperature and suddenly applied, it acts primarily as a stimulant, by the sudden and rapid manner in which the heat is abstracted; next as a tonic, by condensing the living fibres; and finally as a sedative. It is often useful in diseases of relaxation and debility, when practised by affusion or plunging. But it is essential to its efficacy and safety that the stock of vitality should be sufficient to create, immediately after its use, those feelings of warmth and invigoration included under the term reaction. In *febrile diseases* with high bodily temperature the use of the cold bath is a very important therapeutic measure. For details as to method of use, see 10th edition of H. C. Wood's *Treatise on Therapeutics*.

Cold water is frequently applied as a sedative in local *inflammations*, and as a means of restraining *hemorrhage*. Its use, however, is scarcely admissible in *inflammations of the chest*.

Aqua Acidi Carbonici, *Carbonic Acid Water*, or *Soda Water* (so called), (*Aqua acidula simplicior*, F. P.; *Eau gazeuse simple*, Fr.; *Kohlensäure-Wasser*, G.), which was formerly official in the U. S. Pharmacopœia, consists of water highly charged with carbonic acid. Water is found to take up its volume of this gas under the pressure of the atmosphere; and Dr. Henry ascertained that precisely the same *volume* of the compressed gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. From the principles above laid down it follows that, to saturate water with five times its volume of carbonic acid, as directed in the formula, it must be subjected to a pressure of five atmospheres. Carbonic acid gas compressed into the liquid state is now supplied by the "American Carbonate Co." of New York, and its agencies, in wrought-iron cylinders, which contain either 10 or 20 pounds of compressed gas, equal to 600 or 1200 gallons of gas at normal pressure. This allows of convenient transportation, and guarantees the purity of the gas.

Carbonic acid water is familiarly called in this country "*mineral water*" and "*soda water*;" the latter name, originally applied to the preparation when it contained sodium carbonate, being from habit continued since the alkali has been omitted.

Carbonic acid water is dispensed in most of the pharmacies in this country. The fountain is usually placed in the cellar, and the tube proceeding from the fountain is made to pass through the floor and counter of the store, and to terminate in a draught tube, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, or a series of block tin pipes called coolers, placed inside the counter apparatus, and surrounded with ice. For some practical suggestions upon the making of carbonic acid water and use of apparatus, see *N. R.*, June, July, August, 1877.

Properties. Carbonic acid water is a sparkling liquid, possessing an agreeable pungent, acidulous taste. It reddens litmus deeply from its state of concentration, and is precipitated by lime water. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its briskness, it should be kept in strong well-corked bottles placed inverted in a cool place. Several natural waters are of a similar nature, such as those of Selters, Spa, Pyrmont, Apollinaris, etc.; but the artificial water has the advantage of a stronger impregnation with the acid gas. Carbonic acid water should be made with every precaution to avoid metallic impurity. Hence the necessity of having the fountain well tinned on the inner surface. Even with this precaution, a slight metallic impregnation is not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the tubes and stop-cocks. Iron fountains lined with a hard enamel are greatly to be preferred, but the best fountains are now made of cast steel, lined with block tin. When leaden tubes are employed

to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. Tubes of pure tin are free from objection, and should be exclusively used.

Copper fountains, well tinned, are liable to the objections that the tin lining wears away by use, and that there is no convenient means of inspecting the interior, owing to the solder joint which permanently unites the two sections of the fountain. To remove the latter objection, the improvement has been proposed by Dr. R. O. Doremus, of New York, of having the two sections with flanges, securely bolted together, with intervening gutta-percha packing, in order to furnish facilities for examining the interior, to determine whether re-tinning is necessary. Sometimes drops of solder and chips of copper are carelessly left in the fountain, and form an additional source of danger. There can be no doubt that carbonic acid water is not unfrequently rendered poisonous by metallic impregnation. Dr. Doremus has proved by a chemical examination that lead and copper are sometimes present. (*A. J. P.*, 1854, p. 422; from the *Am. Med. Monthly.*) Dr. John T. Plummer, of Richmond, Ind., has found lead. The latter metal is detected by hydrogen sulphide, which gives with it a black precipitate, and copper by potassium ferrocyanide, which causes a brown precipitate. In testing for copper, a few drops of the reagent should be added to a glass of the suspected water, placed on a sheet of white paper, when, if even a minute proportion of copper be present, a brownish discoloration will be seen, upon looking down through the liquid.

Medical Properties and Uses. Carbonic acid water is a grateful drink to *febrile patients*, allaying thirst, lessening *nausea* and *gastric distress*, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, magnesium sulphate, and the saline cathartics generally; rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces (178–236 C.c.) will be sufficient.

AMMONIA. Ammonia.

NH_3; 17·1. (ĄM-MŌ'NĮ-Ą.) NH_3; 17.

All the ammoniacal compounds owe their distinctive properties to the presence of a peculiar gaseous substance, composed of nitrogen and hydrogen, called *ammonia*. This is most easily obtained by the action of lime on ammonium chloride, or sal ammoniac,—when the lime unites with the hydrochloric acid, so as to form calcium chloride and water, and expels the ammonia. It is transparent and colorless, like common air, but possesses an acrid taste and an exceedingly pungent smell. It has a powerful alkaline reaction, and, from this property and its gaseous nature, was called the *volatile alkali* by the earlier chemists. Its sp. gr. is 0·59. It is irrespirable, the glottis closing spasmodically when the attempt is made to breathe it. It consists of one atom of nitrogen and three of hydrogen; or, in volumes, of one volume of nitrogen and three volumes of hydrogen, condensed into two. Its formula is NH_3. The sources of ammonia have been mentioned elsewhere (see *Ammonii Chloridum*, p. 157), but a synthesis of ammonia from simple elements may be noted here. Hydrogen, nitrogen, and aqueous vapor in the presence of porous contact substances like pumice, charcoal, etc., unite to form ammonia, and this, in the presence of CO and CO_2, gives rise to ammonium formate or carbonate.

As the gas ammonia exists in the free state, the molecule NH_3 is a definite saturated compound under ordinary conditions. When, however, ammonia gas is mixed with hydrochloric acid gas or its aqueous solution with hydrochloric acid in solution, the two unite to form a new compound, NH_4Cl, which proves to be a definite compound, analogous to potassium or sodium chlorides. Berzelius, therefore, proposed to call this *ammonium* chloride, assuming that the monad group $(NH_4)^I$ acted like the monad metal K^I in forming compounds. And in fact we find that when sulphuric, nitric, carbonic, and other acids are neutralized by *ammonia* gas or solution we get crystallizable salts like $(NH_4)_2SO_4$, NH_4NO_3 and $(NH_4)_2CO_3$, which we therefore call *ammonium* sulphate, nitrate, and carbonate respectively. These are very similar to the corresponding potassium and sodium salts.

The atmosphere contains a minute proportion of ammonia, probably in the state of carbonate. The alkali is sometimes also found in snow. (A. Vogel, *Neues Repert. für Pharm.*, 1872.)

Ozonized oxygen oxidizes the elements of ammonia, producing water and nitric acid, which latter, by uniting with undecomposed ammonia, generates ammonium nitrate. Ordinary oxygen, under the influence of platinum-black, or finely-divided copper, likewise oxidizes the elements of ammonia, the nitrogen to the extent only of forming nitrous acid, with the result of producing ammonium nitrite.

AQUA AMMONIÆ. U. S. (Br.) Ammonia Water.

(Ā'QUA ĄM-MŌ'NI-Æ.)

"An aqueous solution of Ammonia [$NH_3 = 17{\cdot}01$] containing 10 per cent., by weight, of the gas. Ammonia Water should be kept in glass-stoppered bottles, in a cool place." *U. S.*
"An aqueous solution containing 10 per cent. by weight of ammonia, NH_3." *Br.*

Liquor Ammoniæ, *Br.;* Solution of Ammonia; Water of Ammonia; Liquor Ammonii Caustici, *P.G.;* Spiritus Salis Ammoniaci Causticus, Ammonia Aqua Soluta; Ammoniaque liquide, Eau (Solution, Liqueur) d'Ammoniaque, *Fr.;* Salmiakgeist, Aetzammoniak, Ammoniak-Flüssigkeit, *G.*

The U. S. Pharmacopœia of 1890 omits a process of preparing Ammonia Water. The U. S. P. 1870 contains an excellent process, which is appended.*

"Strong Solution of Ammonia, 1 *pint* (Imperial measure) or 500 cubic centimetres; Distilled Water, 2 *pints* (Imp. meas.) or 1000 cubic centimetres. Mix." *Br.*

The title of this preparation was changed, at the revision of the U. S. Pharmacopœia in 1860, from Liquor Ammoniæ to Aqua Ammoniæ, that it might conform in name as well as character with the Waters, among which all the official preparations consisting of aqueous solutions of gaseous bodies are included. In the revision of 1890 the English name was changed from Water of Ammonia to Ammonia Water.

In the U. S. P. 1870 process, the ammonium chloride is decomposed by the superior affinity of the lime for its acid, ammonia is disengaged, and the lime, combining with the acid, forms calcium chloride and water, $2NH_4Cl + Ca2HO = CaCl_2 + 2H_2O + 2NH_3$. The process differs from that of 1850 in introducing the materials into the retort with a large quantity of water, instead of in the dry state. In both cases the gas is driven over by heat, but in the moist plan is accompanied with more watery vapor than in the dry. If the object were to obtain ammonia water in the highest possible state of concentration, there might be some advantage in the dry method; but, as a weak solution is contemplated, the wet method is equally efficient, while in all respects it is more convenient, and productive of better results; for, according to Dr. Squibb, the ammonia water made by the older official process has invariably an empyreumatic odor, from which that made by the present process is free. (*Proc. A. P. A.*, 1858, p. 407.) The receiver is intended to retain any water holding in solution undecomposed chloride, or the oily matter sometimes contained in the salt, as well as other impurities, which may be driven over by the heat while the pure gas passes forward into the bottle containing the distilled water, which should not fill it, on account of the increase in the bulk of the water during the absorption of the gas. The tube should extend to near the bottom of the bottle, and pass through a cork loosely fitting its mouth. To prevent the regurgitation of the water from the bottle into the intermediate vessel, the latter should be furnished with a Welter's safety tube. Very large bottles are improper for keeping the ammonia water; as, when they are partially empty, the atmospheric air within them may furnish a little carbonic acid to the ammonia.

In preparing solution of ammonia, equal weights of ammonium chloride and lime are used for generating the gaseous ammonia. This proportion gives a great excess of lime, compared with the quantity required if determined by the molecular weights; but in practice it is found advantageous to have an excess, as well to insure the full decomposition of the ammonium chloride, as to make up for accidental impurities in the lime.

The British Pharmacopœia gives directions for diluting *Liquor Ammoniæ Fortior* so as to reduce it to the strength of *Liquor Ammoniæ*. This is effected by mixing one measure of their stronger preparation with two measures of distilled water. The ammonia water of commerce is known as "Aqua Ammoniæ F. F. F.," or "20° ammonia;" it may be diluted by adding 2 parts of water to 3 parts of 20° ammonia water to make official ammonia water. Ammonia water of other strengths may be diluted by consulting the table given on page 204, and applying the rules given in *Remington's Practice of Pharmacy*, p. 91.

Properties. Ammonia water is "a colorless, transparent liquid, having a very pungent

* "Take of Chloride of Ammonium, in small pieces, Lime, each, *twelve troyounces;* Water *six pints;* Distilled Water *a sufficient quantity.* Pour a pint of the Water upon the Lime, in a convenient vessel; and, after it has slaked, stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Chloride of Ammonium. Place the retort on a sand-bath, and adapt to it a receiver purposely connected with a two-pint bottle, by means of a glass tube, reaching nearly to the bottom of the bottle, and containing a pint of Distilled Water. Surround the bottle with ice-cold water; and apply heat, gradually increased, until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient Distilled Water to raise its specific gravity to 0·960. Lastly, keep the liquid in small bottles, well stopped." *U. S.*

odor, an acrid, alkaline taste, and a strongly alkaline reaction. Specific gravity, 0·960 at 15° C. (59° F.). It is completely volatilized by the heat of a water-bath. On bringing a glass rod dipped into hydrochloric acid near the liquid, dense, white fumes are evolved. On slightly supersaturating 10 C.c. of Ammonia Water with diluted sulphuric acid, no *empyreumatic odor* or *red color* should be developed, and if to this liquid 1 C.c. of potassium permanganate centinormal volumetric solution be added, the pink color should not be completely destroyed within ten minutes (absence of *readily oxidizable matters*). If Ammonia Water be mixed with 4 times its volume of calcium hydrate test-solution, it should not afford an immediate turbidity (only minute traces of *carbonic acid*); and if it be diluted with twice its volume of water, it should not be affected by ammonium oxalate test-solution (absence of *calcium*), nor should it be affected by hydrogen sulphide test-solution, either before or after neutralization with hydrochloric acid (absence of *metallic impurities*). If Ammonia Water be slightly supersaturated with nitric acid, it should not be affected by barium chloride test-solution (absence of *sulphates*), nor by silver nitrate test-solution (*chlorides*); and if a third portion of the acidulated liquid be evaporated on a water-bath to dryness, it should afford a colorless residue, which, on ignition, should be completely volatilized (absence of *coal-tar bases*, and of *fixed impurities*). To neutralize 3·4 Gm. (3·54 C.c.) of Ammonia Water should require 20 C.c. of normal sulphuric acid (each C.c. corresponding to 0·5 per cent. of Ammonia), rosolic acid being used as indicator." *U. S.* Of the British preparation, "Each gramme should require for neutralization 5·9 cubic centimetres of the *volumetric solution of sulphuric acid*. It should respond, qualitatively, to the characters and tests described under 'Liquor Ammoniæ Fortis.' Specific gravity 0·959." *Br.*

Ammonia Water is incompatible with acids, and with acidulous and many earthy and metallic salts; but it does not decompose the salts of lime, baryta, or strontia, and only partially decomposes those of magnesia. Commercial solution of ammonia sometimes contains *pyrrol*, *naphtalin*, *aniline*, and *pyridine*. These may be detected by the solution being reddened by nitric acid, and, after having been supersaturated with hydrochloric acid, by its tingeing a slip of fir wood of a rich purple color, characteristic of pyrrol. (*Maclagan.*) The source of these impurities is coal-gas liquor, from which the ammoniacal compounds are largely obtained. Donath (*Dingler's Polytechnisches Journal*, vol. iv. p. 229) tested some ammonia prepared from gas liquor by neutralizing with diluted sulphuric acid, when the liquid assumed a rose-color, and a solution of the sulphate emitted the characteristic odor of naphtalin.

Composition. Water is capable of absorbing 670 times its volume of ammoniacal gas at 10° C. (50° F.), and increases in bulk about two-thirds. But the official solution of ammonia is by no means a saturated one. Thus, the ammonia contained in the U. S. preparation is about 10 per cent. The following table gives the percentage of ammoniacal gas in aqueous solutions of different densities at the temperature of 15° C. (*Lunge.*)

Per cent. of Ammonia.	Specific Gravity at $\frac{15°\ C.}{4°\ C.}$ in air.	Per cent. of Ammonia.	Specific Gravity at $\frac{15°\ C.}{4°\ C.}$ in air.	Per cent. of Ammonia.	Specific Gravity at $\frac{15°\ C.}{4°\ C.}$ in air.	Per cent. of Ammonia.	Specific Gravity at $\frac{15°\ C.}{4°\ C.}$ in air.

Medical Properties and Uses. When brought into contact with living tissue, ammonia acts as a stimulant, irritant, or caustic, according to the strength of its solution. When

applied to the skin, it may excite simply burning pain and redness, but in the form even of the present preparation, if the contact be sufficiently maintained, it is capable of destroying the whole dermal tissue; taken internally in a concentrated form, it acts as a violent corrosive poison, and may cause rapidly fatal gastro-enteritis, with the destruction of the visceral coats. In some cases it has produced death in a few minutes by entering the larynx and causing œdema, with consequent suffocation. When taken internally in therapeutic doses its action is immediate, and continues but for a few moments. In the stomach it acts as a stimulant antacid, and is often useful in *heartburn*, *sick headache*, etc. After absorption it stimulates most powerfully the circulation and respiration, affecting especially the heart and respiratory centres. By full doses the respiratory rate and the arterial pressure are for a few moments enormously increased. Toxic doses are directly paralyzant to the heart muscle, and may cause, if injected into a vein, immediate diastolic arrest of the heart. According to Bence Jones, ammonia is oxidized in the system, with the formation of nitric acid, which is eliminated by the kidneys.

Ammonia water is a valuable remedy in all forms of sudden *syncope*. The injection of ammonia into a vein was brought forward by Prof. G. B. Halford, of Melbourne, as a specific against the *poison of serpents*, and some evidence has been adduced as to its value. As long ago, however, as 1782, Fontana published at Florence a series of experiments showing the uselessness of such injections as a remedy for *snake-bite*, and more recently the subject has been investigated in India by Sir Joseph Fayrer (*Indian Annals Med. Sci.*, 1872), and by a Royal Commission (*Lancet*, Sept. 1874), with the result of completely establishing the truth of the experiments and conclusions of Fontana. In *collapse* following severe accident, or in sudden *cardiac failure* from other acute cause, the intravenous injection of aqua ammoniæ has been of the greatest service in arousing the action of the heart. Half a drachm to a drachm diluted with half an ounce to an ounce of water may be slowly thrown directly into a vein. In some cases the drug has been simply used hypodermically, but is almost certain to cause severe local symptoms. On account of its cheapness, ammonia water is much used as an ingredient in liniments, especially combined with olive or other oil. The internal dose is from ten to thirty drops (0·6–1·9 C.c.), largely diluted.

AQUA AMMONIÆ FORTIOR. U. S. (Br.) Stronger Ammonia Water.

(Ā'QUẠ ẠM-MŌ'NI-Æ FÖR'TI-ỌR.)

"An aqueous solution of Ammonia [$NH_3 = 17·01$] containing 28 per cent., by weight, of the gas. Stronger Ammonia Water should be kept in strong, glass-stoppered bottles, not completely filled, in a cool place." *U. S.* "An aqueous solution containing 32·5 per cent. by weight of ammonia, NH_3. It may be obtained by heating a mixture of ammonium chloride and slaked lime, and passing the resulting ammonia into distilled water." *Br.*

Liquor Ammoniæ Fortis, *Br.*, Strong Solution of Ammonia; Eau d'Ammoniaque forte, *Fr.*; Stärker Salmiakgeist, *G.*

This preparation is too strong for internal exhibition, but forms a convenient ammoniacal solution for reduction, by dilution with two measures of distilled water, to the strength of ordinary Ammonia Water (Aqua Ammoniæ), or for preparing strong rubefacient liniments.

The U. S. Pharmacopœia does not give a process. The process of the British Pharmacopœia (1885) will be found in detail in the U. S. D., 17th ed., p. 202.

Ammonia Water is seldom made by the formula of the Pharmacopœia, but is prepared on a large scale, from one of the products of the coal-gas manufacture, by the following more economical process. *Gas liquor* is distilled, and the distillate, which is principally ammonium sulphide, is converted into ammonium sulphate by sulphuric acid. The rough sulphate is then gently distilled with milk of lime, the still being connected with a series of glass carboys, arranged like Woulf's bottles, and three-fourths filled with distilled water. In this way solution of ammonia may be obtained of maximum strength.

Properties of Aqueous Ammonia of Maximum Strength. This is a colorless liquid, of an acrid taste and very pungent smell. It is strongly alkaline, and immediately changes turmeric, when held over its fumes, to reddish brown. Cooled to 40° F. below zero, it concretes into a gelatinous mass, and at 54° C. (130° F.) boils, owing to the rapid disengagement of the gas. Its sp. gr. is 0·875 at 10° C. (50° F.). Anhydrous ammonia is said to dissolve metallic sodium, and the solution is intensely blue. (*Chem. News*, Nov. 4, 1870, p. 217.)

Properties of the Official Stronger Ammonia Water. This has similar properties to those above mentioned. Its sp. gr. is 0·901, *U. S.*, 0·891, *Br.* When of the former density,

it contains 28 per cent. of the gas; when of the latter, 32·5 per cent.* "To neutralize 1·7 Gm. (1·88 C.c.) of Stronger Ammonia Water should require 28 C.c. of normal sulphuric acid (each C.c. corresponding with 1 per cent. of ammonia), rosolic acid being used as indicator." *U. S.* The stronger ammonia water of commerce usually ranges in density from 0·900 to 0·920. Even when of proper official strength at first, it generally becomes weaker by the escape of ammonia. To prevent its deterioration, it should be kept in closely-stoppered bottles in a cool place. If precipitated by lime water it contains carbonic acid. After having been saturated with nitric acid, a precipitate by ammonium carbonate indicates earthy impurity, by silver nitrate, a chloride, and by barium chloride, a sulphate. "When mixed with an equal volume of *water*, with the addition of a slight excess of *hydrochloric acid*, no color or odor should be developed (absence of tarry matters). It should not yield any characteristic reaction with the tests for arsenium, lead, iron, aluminium, zinc, calcium, magnesium, potassium, sodium, carbonates, sulphates, or sulphides, and only the slightest reactions with the tests for chlorides. Specific gravity 0·891. Each gramme should require for neutralization 19·1 cubic centimetres of the *volumetric solution of sulphuric acid*." *Br.*

When purchasing the Stronger Solution of Ammonia, the apothecary should not trust to its being of the official strength, but should ascertain the point by taking its density, either by the specific gravity bottle or the hydrometer. Another method of ascertaining its density is by the *ammonia-meter* of Mr. J. J. Griffin, of London, described and figured in *P. J. Tr.* (x. 413). Although the U. S. Pharmacopœia states that "if stronger ammonia water be diluted with twice its volume of water it should respond to the reactions and tests described under Ammonia Water," it will be usually found in practice that two volumes of water will be too much; in any event it would be safer to use a smaller quantity of water (one and a half volumes), and, if the mixture should not have the sp. gr. 0·960, it should be brought to that density by the addition either of the stronger solution or of distilled water, as the case may require. "Stronger Ammonia Water should be kept in strong glass-stoppered bottles, not completely filled, in a cool place." *U. S. Great care should be exercised in opening these bottles.* It is safer, if the ammonia water has been kept in a warm room, to cool it with ice before attempting to withdraw the stopper, as the liberated gas, when warm, oftentimes is forced out with extreme violence, and accidents resulting in injury to the sight of the operator are recorded.

Medical Properties and Uses. This solution is too strong for medical use in its unmixed state. Sufficiently diluted with spirit of camphor and rosemary, it has been much employed as a prompt and powerful rubefacient, vesicatory, or escharotic, in various *neuralgic*, *gouty*, *rheumatic*, *spasmodic*, and *inflammatory affections* in which strong and speedy counter-irritation is indicated. When mere rubefaction is desired, a mixture may be used composed of five fluidounces of the ammoniacal liquid and eight of the diluent liquid; and this will answer even for blistering or cauterizing, unless a very prompt effect be necessary. In the latter case a lotion may be resorted to consisting of five measures of the ammoniacal to three of the diluent liquid. These mixtures are applied by means of linen folded several times, or a thick piece of flannel saturated with the liniment. A convenient mode is to fill the wooden cover of a large pill- or ointment-box, an inch or two in diameter, with patent lint, saturate this with the liquid, and press it upon the part. The ammonia is thus prevented from escaping, and a definite boundary given to the inflammation. The application will generally produce rubefaction in from one to eight minutes, vesication in from three to ten minutes, and a caustic effect in a somewhat longer time.

When a solution of ammonia of 25° (sp. gr. 0·905) is mixed with fatty matter, the mixture forms the *vesicating ammoniacal ointment* of Dr. Gondret. The revised formula of this ointment is as follows. Take of lard 32 parts, oil of sweet almond 2 parts. Melt them together by the *gentle* heat of a candle or lamp, and pour the melted mixture into a bottle with a wide mouth. Then add 17 parts of solution of ammonia of 25°, and mix with continued agitation until the whole is cold. The ointment must be preserved in a bottle with a ground stopper, and kept in a cool place. When well prepared, it vesicates in ten minutes. There may be danger of excessive irritation and inflammation of the nostrils, mouth, and air-passages, from the inadvertent inhalation of the gas escaping from a bottle of the stronger water of ammonia, when freshly opened; and serious consequences have occurred from this cause, or from the accidental breaking of the bottle. The best antidote, under these circumstances, would be the inhalation of the vapors of vinegar or acetic acid.

* This percentage (32·5) corresponds, according to Lunge, with ammonia water of sp. gr. 0·888 instead of 0·891.

AQUA AMYGDALÆ AMARÆ. U. S. Bitter Almond Water.

(Ā'QUĄ Ą-MĬG'DĄ-LÆ Ą-MĀ'RÆ.)

Aqua Amygdalarum Amararum, *P.G.;* Eau d'Amandes amères, *Fr.;* Bittermandelwasser, *G.*

"Oil of Bitter Almond, *one cubic centimeter* [or 16 minims]; Distilled Water, *nine hundred and ninety-nine cubic centimeters* [or 33 fluidounces, 6 fluidrachms, 14 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Oil in the Distilled Water by agitation, and filter through a well-wetted filter." *U. S.*

Owing to the almost universal employment at this time (1898) of artificial oil of bitter almond (or benzaldehyde), which is free from hydrocyanic acid (such oil being much cheaper than that made from bitter almond), the bitter almond water of pharmacy cannot be relied upon as a medicinal agent, but is used exclusively as a pleasant vehicle. This must be regarded as a fortunate circumstance, because the proportion of hydrocyanic acid was very variable in the former bitter almond water, and doubt and uncertainty about its action always prevailed. Notwithstanding these facts, care must be exercised not to prescribe a larger dose to begin with than two teaspoonfuls (7·5 C.c.), lest the water should have been made from the poisonous oil of bitter almond.* Its principal use in this country is as a vehicle, many physicians prescribing it not for its medicinal virtues, but on account of its agreeable taste and powers of masking the taste of saline substances. Under the same name, a preparation has been much used on the continent of Europe, prepared by distilling bitter almonds with water.† This when fresh is much stronger than the preparation of the U. S. Pharmacopœia, containing, according to an analysis of Geiger, in 1000 parts, 1·2 parts of anhydrous hydrocyanic acid. But, in consequence either of circumstances in the manner of its preparation, or of changes upon being kept, it is of variable and uncertain strength, and cannot be relied on.‡ It has been prescribed with fatal effects; and the greatest caution, therefore, should be observed by the apothecary not to dispense the distilled bitter almond water instead of the official.

AQUA ANETHI. Br. Dill Water.

(Ā'QUĄ Ą-NĒ'THĪ.)

Eau d'Aneth, *Fr.;* Dillwasser, *G.*

"Dill Fruit, 1 *pound* (Imperial) or 500 grammes; Water, 2 *gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

This water, which is frequently prescribed in Great Britain, is occasionally used here; it closely resembles caraway water, over which it has no advantages.

AQUA ANISI. U. S., Br. Anise Water.

(Ā'QUĄ Ą-NĪ'SĪ.)

Eau d'Anis, *Fr.;* Aniswasser, *G.*

"Oil of Anise, *two cubic centimetres* [or 32 minims]; Precipitated Calcium Phosphate, *four grammes* [or 62 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic cen-*

* Under the name of *chloral hydrocyanate* a substance has been introduced for making cherry-laurel and bitter almond water extemporaneously. It occurs in white, translucent, rhombic prisms, soluble in water, alcohol, and ether. It has the odor of hydrocyanic acid and chloral, and is said to be a very stable compound. A solution of 6·5 grains of the salt in 1000 grains of distilled water corresponds with the official bitter almond water of the German Pharmacopœia, which is 1 to 1000. (*Merck's Bulletin.*)

† *Preparation of Bitter Almond Water* (Distilled). H. C. Vielhaber powders ten pounds of bitter almonds as finely as possible, separates the fatty oil, which usually amounts to 36 to 38 per cent., by strong pressure, and reduces the almond press-cake to a very fine powder; a quantity of this corresponding to two pounds of almonds is then distilled with water (without alcohol) until about 500 grammes of distillate have been obtained, when the receiver is disconnected, and another receiver attached, and the distillation continued as long as the presence of hydrocyanic acid can be recognized by its odor and taste in the distillate; this second distillate is then used in the place of distilled water for distilling another two-pound lot of the almonds, and the operation continued thus, always collecting the first and second distillates separately and utilizing the latter for distilling the next lot, until all the press-cake has been subjected to distillation; the first distillates are mixed, and also the second. The author thus obtained from 10 pounds of almonds about 5 pounds of first and 9 to 10 pounds of second distillate, the former containing a large percentage of volatile almond oil, which is dissolved by adding the official (Ph. Germ.) percentage of alcohol (about ¼ of its weight) to the distillate. The percentage of hydrocyanic acid is then determined in the first and second distillates, and sufficient of the latter added to the former to reduce it to the official strength (one-tenth of one per cent.). (*Archiv d. Pharm.*, May, 1879, p. 409; *A. J. P.*, July, 1879.) G. A. Zwick prepares distilled bitter almond water by breaking up 12 pounds of peach kernels in a mill, then powdering finely, expressing 25 per cent. of fixed oil, powdering the press-cake, introducing this into a still, with water, reserving the first forty fluidounces of distillate, this having been shown by assay to contain the proper amount of hydrocyanic acid, one per mille. (*A. J. P.*, 1881. See also *Pharm. Post*, 1894, 193; *Zeitschr. für Anal. Chem.*, 1894, 193.)

‡ For a method of determining the amount of hydrocyanic acid in bitter almond water, see *Archiv d. Pharm.*, Nov. 1878, 408; *A. J. P.*, Feb. 1879; *Zeitschr. Oest. Apoth. Ver.*, 1893, 45, 344, 387, 391.

timeters [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Anise with the precipitated Calcium Phosphate, add the Water gradually, under constant trituration, and filter." *U. S.*

"Anise Fruit, 1 *pound* (Imperial) or 500 grammes; Water, 2 *gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Anise water is rarely made by distillation, although the product thus secured has a more delicate flavor than the U. S. preparation. It is used solely as a vehicle.

AQUA AURANTII FLORUM. U. S. (Br.) Orange Flower Water.

(Ā'QUA ÂU-RĂN'TI-Ī FLŌ'RŬM—âu-răn'shę-ī.)

"The orange-flower water of commerce, prepared by distillation from the flowers of the Bitter Orange tree, Citrus Aurantium, var. Bigaradia, diluted, immediately before use, with twice its volume of Distilled Water." *Br.*

Aqua Aurantii Floris, *Br.*, Orange Flower Water; Aqua Florum Naphæ; Eau (Hydrolat) distillée de Fleurs d'Oranger, Eau de Naphe, *Fr.*; Orangenblüthenwasser, *G.*

"Stronger Orange Flower Water, Distilled Water, of each, *one volume*. Mix them immediately before use." *U. S.*

The U. S. Pharmacopœia, 1890, has introduced "Stronger Orange Flower Water," providing for its dilution with an equal volume of distilled water to make "orange flower water." This plan enables American pharmacists to employ the imported "triple" water, as it is known in commerce. This retains its fragrance longer than a weaker water; moreover, economy is effected through saving customs duty and freight, and a fresh, delicate water can be dispensed.

This preparation is also considered by the British Pharmacopœia as an object of importation. According to this authority, it is obtained from the flowers of the bitter orange tree; this is concurred in by our own official standard. In Italy and France, where it is largely made, the flowers of the bitter orange have long been preferred, as yielding the most fragrant product. It may be prepared in the most southern districts of our country from the fresh flowers; and these might be brought to the North for the same purpose, if previously incorporated with one-third or one-quarter of their weight of common salt. The proper method is to arrange the flowers and salt in successive layers in jars of stoneware or glass. They may also be preserved by means of glycerin. Notwithstanding, however, the facility of preparing this Water here, it is generally imported from the south of France, whence it usually comes in cans of tinned copper.

Orange flower water is nearly colorless, though often of a pale yellowish tint. "Stronger Orange Flower Water should be neutral to litmus paper, and possess a strong odor of fresh orange flowers. It should be colorless and clear, or only faintly opalescent, not mucilaginous, and give no reaction with hydrogen sulphide test-solution or ammonium sulphide test-solution (absence of *metallic impurities*)." *U. S.* From being kept in tinned copper cans, it sometimes contains metallic impurity, which is said to be chiefly carbonate of lead, derived from the lead used as a solder in making the cans. The means of detecting metallic impurity are mentioned under the general observations on distilled water. Much color, offensive odor, or mouldiness indicates impurity derived from the flowers in distillation.

L. Malenfant observed that fresh orange flowers, mixed with cold water, yield, on distillation over the naked fire, a milky water, possessing a somewhat empyreumatic odor and a strong, somewhat acrid taste. Kept for twelve or eighteen months in glass vessels covered with parchment, it loses its empyreuma, and after filtering has an agreeable odor and taste. If the flowers be mixed with boiling water and immediately distilled, the water is limpid, and gradually separates some thick oil of a brownish color; the water has the odor and taste of the flowers, but complicated with a smell of the still, which it loses after long keeping; it seems to alter less rapidly than that obtained by the former process. Distilled by steam, a limpid water of a pure odor and taste is at once obtained, free from empyreuma; it may be at once used, and keeps better in the light than when obtained by the two former processes. (*A. J. P.*, June, 1874.) A distilled water of the leaves is also prepared; and sometimes a mixture of the leaves and flowers is employed. But this is a fraud, as the distilled water of the leaves never has the sweet perfume of that of the flowers. (*Journ. de Pharm.*, 4e sér., iii. 249.) Orange flower water is used exclusively on account of its agreeable odor.

Orange flower water is stored in large glass vessels or carboys in cool cellars by the manufacturers in Grasse, care being taken not to stopper them tightly, but simply to cover the orifice with a piece of paper.

Nitric, sulphuric, or hydrochloric acid produces a red coloration with orange flower water; particularly if the water be shaken with ether to take up the oil, and the acid added to the ethereal solution. (*P. J. Tr.*, 1878, 248.)

AQUA AURANTII FLORUM FORTIOR. U. S. Stronger Orange Flower Water. [Triple Orange Flower Water.]

(Ā'QUẠ ÂU-RĂN'TI-Ī FLŌ'RŬM FÖR'TI-ỌR.)

"Water saturated with the volatile oil of fresh Orange Flowers, obtained as a by-product in the distillation of the Oil of Orange Flowers. It should be kept in loosely-stoppered bottles, in a dark place." *U. S.* The orange flower water of commerce is a saturated solution of the essential oil of the fresh flowers. (See *Aqua Aurantii Florum*, p. 208.)

Aqua Aurantii Florum, *U. S.* 1880.

AQUA CAMPHORÆ. U. S., Br. Camphor Water.

(Ā'QUẠ CĂM'PHỌ-RÆ.)

Mistura Camphoræ, *Br.*; Aqua Camphorata; Eau camphrée, *Fr.*; Kampferwasser, *G.*

"Camphor, *eight grammes* [or 123½ grains]; Alcohol, *five cubic centimeters* [or 81 minims]; Precipitated Calcium Phosphate, *five grammes* [or 77 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Camphor with the Alcohol and Precipitated Calcium Phosphate, then with the Water, gradually added, and filter." *U. S.*

"Camphor, 70 *grains* (Imperial) or 5 grammes; Alcohol (90 per cent.), *a sufficient quantity*; Distilled Water, 1 *gallon* (Imp. meas.) or 5 litres. Dissolve the Camphor in a sufficient quantity of the Alcohol to form half a fluid ounce (or fifteen cubic centimetres) of the solution; add this in successive portions to the Distilled Water, shaking after each addition; finally agitate occasionally until all the Camphor is dissolved." *Br.*

In both of these processes the sole object is to effect a solution; water is capable of dissolving but a very small proportion of camphor; but the quantity varies with the method employed. The present official process is an improvement on former methods, for it undoubtedly secures a transparent saturated solution easily and rapidly; the mere trace of calcium phosphate which dissolves in the water may be disregarded. The present British process is more efficient than the old formula, a definite quantity of camphor being dissolved in a small quantity of alcohol and this solution gradually added to the proper quantity of water; it is questionable, however, whether it would not be advantageous to use an insoluble powder to aid in the solution and thus obtain quickly a clear liquid, as the water made by the British process is sometimes cloudy. In the former British process no trouble was taken even to comminute the camphor, or to shake it with the water, which was thus allowed to take up what it might be disposed to do by contact with the camphor contained in a bag. The solution thus effected was extremely feeble, containing probably less than one part in a thousand; this proportion, according to Berzelius, is taken up by water when triturated with camphor. It was, besides, of uncertain strength, varying with the size of the fragments of camphor. Mr. J. C. Pooley found that 120 grains of camphor, treated according to the official directions, gave, when cut into 4 pieces, 6 grains to half a gallon of water, but in 20 pieces gave 20 grains, or about one part to 1750 of water. (*P. J. Tr.*, 2d ser., vii. 162.) Mr. Wm. B. Addington proposed to add to the camphor just enough alcohol to dissolve it, and triturate the liquor with magnesia, during which process he affirmed that the alcohol evaporated (*A. J. P.*, xlv. 209); and Mr. F. T. Hartzell substituted for alcohol, ether, a few drops of which enabled him to bring the camphor to an impalpable powder. (*Ibid.*, xlvi. 233.) The camphor is separated from its aqueous solution by a solution of pure potassa, and, according to Dr. Paris, by magnesium sulphate and several other salts. Sir J. Murray proposes a solution of camphor and magnesium bicarbonate, which contains three grains of the former and six grains of the latter in each fluidounce.

Camphor water has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is too feeble a preparation for use when a decided effect is desired; it is, however, an excellent vehicle for the administration of more active substances. It is usually given in the dose of one or two tablespoonfuls (15–30 C.c.), repeated every hour or two hours.

AQUA CARUI. Br. Caraway Water.

(Ā'QUA CĂR'Ū-Ī.)

Aqua Carvi; Eau distillée de Carvi, *Fr.;* Kümmelwasser, *G.*

"Caraway Fruit, 1 *pound* (Imperial) or 500 grammes; Water, 2 *gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Distilled Caraway Water has the flavor of the fruit or seeds, but is seldom used in the United States. The water made from the volatile oil (15 minims in a pint), in the same manner as is cinnamon water, is largely employed.

AQUA CHLORI. U.S. (Br.) Chlorine Water.

(Ā'QUA ØHLŌ'RĪ.)

"An aqueous solution of Chlorine [Cl = 35·37], containing at least 0·4 per cent. of the gas." *U. S.* "Produced by saturating Distilled Water with chlorine. The chlorine may be obtained by the interaction of Hydrochloric Acid and Manganese Peroxide, and should be purified by passing through a small quantity of water contained in a wash-bottle." *Br. Appendix.*

Solution of Chlorine, *Br.;* Aqua Chlorata, *P.G.;* Aqua Chlori, Chlorum Solutum, Aqua Oxymuriatica; Eau chlorée, Chlore liquide, *Fr.;* Chlorwasser, *G.;* Aqua Chlorini, *Phar.* 1870.

"Manganese Dioxide, *ten grammes* [or 154 grains]; Hydrochloric Acid, *thirty-five cubic centimeters* [or 1 fluidounce, 88 minims]; Water, *seventy-five cubic centimeters* [or 2½ fluidounces]; Distilled Water, *four hundred cubic centimeters* [or 13½ fluidounces]. Place the Dioxide in a flask connected by a suitable tube with a small wash-bottle containing *fifty cubic centimeters* [or 1½ fluidounces] of Water, and connect this with a bottle having a capacity of *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms], and containing *four hundred cubic centimeters* [or 13½ fluidounces] of Distilled Water which has previously been boiled and allowed to cool. Add to the Dioxide in the generating flask the Hydrochloric Acid, previously diluted with *twenty-five cubic centimeters* [or 1 fluidounce] of Water, and, by means of a sand-bath, apply a gentle heat. Conduct the generated Chlorine through the Water contained in the wash-bottle into the bottle containing the Distilled Water, which should be loosely stopped with cotton and kept, during the operation, at a temperature of about 10° C. (50° F.). When the air has been entirely displaced by the gas, disconnect the bottle from the apparatus, and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas and agitating, until the Distilled Water is saturated. Finally, pour the Chlorine Water into small, dark amber-colored, glass-stoppered bottles, which should be completely filled therewith, and keep them in a dark and cool place. Chlorine Water, even when kept from light and air, is apt to deteriorate. When it is required of full strength, it should be freshly prepared." *U. S.*

The British Pharmacopœia of 1898 transferred solution of chlorine to the Appendix and omitted a detailed process.

In both processes, the chlorine gas is extricated from the hydrochloric acid by the manganese dioxide,* whilst the manganous chloride and water produced remain in the flask, and the chlorine is passed, through an intermediate vessel containing a little water for purifying it, into the bottle containing the distilled water, loosely stopped, until the vacant part of the bottle is filled with it to the exclusion of the atmospheric air. $MnO_2 + 4HCl = MnCl_2 + Cl_2 + 2H_2O$. The bottle, being then corked, is shaken so as to cause the absorption of the gas by the water. Of course the stopper must be from time to time loosened, in order to allow the entrance of air to supply the partial vacuum created by the absorption of the chlorine. The chlorine water is directed to be kept secluded from the light, because otherwise it would be apt to be converted partially into hydrochloric acid, through the union of the chlorine with the hydrogen of the water.†

An *extemporaneous chlorine water*, which has the objection of not being pure, containing

* The manganese oxide is of course deoxidized. In manufacturing chlorine on the large scale, it is of great importance to reoxidize the manganese, so that it can be used over again. This was first accomplished by Mr. Walter Weldon in 1870, and his "manganese regeneration" process has been universally adopted. It is said that a few years ago there were only two chlorine works in the world that did not regenerate their manganese. For details, see *Roscoe and Schorlemmer's Chemistry*, vol. ii. part ii. p. 15.

† *Deacon's process.* Mr. Henry Deacon has discovered that chlorine may be made by passing hydrochloric acid vapor and oxygen over copper sulphate at a temperature of from 400° to 700° F., the copper salt coming out unchanged. For details of this process the reader is referred to *Roscoe and Schorlemmer's Chemistry*, vol. i. p. 114.

potassium chloride and free hydrochloric acid, not more than twenty-four and twelve grains respectively to the pint, may be made as follows. Put in a bottle forty grains of potassium chlorate, add one-half troyounce of hydrochloric acid. When the bottle begins to be filled with chlorine vapors, add one fluidounce of distilled water. Stopper the bottle, and, when the crystals have dissolved, add distilled water to make a pint. (*A. J. P.*, xlii. 208.) The reaction liberates, however, at the same time, the somewhat explosive gas Cl_2O_4, and may be dangerous at times.

Properties. "A clear, greenish-yellow liquid, having the suffocating odor and disagreeable taste of Chlorine, and leaving no residue on evaporation. It instantly decolorizes dilute solutions of litmus, indigo, and other vegetable coloring matters. When shaken with an excess of mercury until the odor of Chlorine has disappeared, the remaining liquid should be at most but faintly acid (limit of *hydrochloric acid*). On adding 17·7 Gm. of Chlorine Water to a solution of 1 Gm. of potassium iodide in 10 C.c. of water, the resulting deep-red liquid should require for complete decoloration not less than 20 C.c. of sodium hyposulphite decinormal volumetric solution (corresponding to at least 0·4 per cent. of Chlorine)." *U. S.* Like gaseous chlorine, it destroys vegetable colors. When cooled to about the freezing point, it forms deep yellow crystalline plates, consisting of chlorine hydrate. It is intended to contain at least twice its volume of the gas. According to MM. Riegel and Walz, chlorine water containing two and a half volumes of the gas at 12·2° C. (54° F.) keeps best. The official test indicates the quantity of chlorine in the solution, by the amount of the hyposulphite required to decolorize an equivalent quantity of iodine, liberated from the potassium iodide. Chlorine water decomposes on keeping, and the British Pharmacopœia directs that "it should be recently prepared." In view of the unstable properties of chlorine water, liquid chlorine in sealed glass tubes (each containing five grammes) can be procured in commerce, the contents of one tube being sufficient to prepare a litre of the water.

Chlorine is an elementary gaseous fluid of a greenish-yellow color and characteristic smell and taste. It is a supporter of combustion. Its specific gravity is 2·47, and its atomic weight 35·37. When the attempt is made to breathe it, even much diluted, it excites cough and a sense of suffocation, and causes a discharge from the mucous membrane of the nostrils and bronchial tubes. Breathed in considerable quantities, it produces spitting of blood, violent pains, and sometimes death.

Medical Properties and Uses. Chlorine water is stimulant and antiseptic. Internally it has been used in *typhus*, and in *chronic affections of the liver;* but the diseases in which it has been most extolled are *scarlatina*, *malignant sore throat*, and *diphtheria*. Externally it is employed, duly diluted, as a gargle in *small-pox*, *scarlatina*, and putrid *sore throat*, as a wash for ill-conditioned *ulcers* and *cancerous sores*, and as a local bath in *diseases of the liver*. It has been used with advantage as an application to *buboes* and large *abscesses*, to promote the absorption of the matter. As it depends upon chlorine for its activity, its medical properties coincide with those of chlorinated lime and chlorinated soda, under which heads they are more particularly given. The dose of chlorine water is from one to four fluidrachms (3·75–15 C.c.), properly diluted. It should not be prescribed in mixtures, almost all organic substances causing a rapid disappearance of the chlorine. Even sugar has this action, and glycerin still more markedly. (*A. J. P.*, xliv. 163.)

Gaseous chlorine has been recommended by Gannal in *chronic bronchitis* and *pulmonary consumption*, exhibited by inhalation, in minute quantities, four or six times a day. Its first effect is to produce some dryness of the fauces, with increased expectoration for a time, followed ultimately by diminution of the sputa and by amendment. Dr. Christison states that he has repeatedly observed these results in *chronic catarrh;* and both he and Dr. Elliotson have obtained, in consumption, a decided improvement of the symptoms. The liquid in the inhaler may be formed either of water containing from ten to thirty drops (0·6–1·9 C.c.) of chlorine water, or of chlorinated lime dissolved in forty parts of water, to which a drop or two of sulphuric acid must be added, each time the inhalation is practised. The inhaler should be placed in water heated to about 37·7° C. (100° F.).

AQUA CHLOROFORMI. U. S., Br. Chloroform Water.

(Ā'QUA ȻHLŌ-RO-FÖR'MĪ.)

Eau de Chloroforme, *Fr.;* Chloroformwasser, *G.*

"Chloroform, Distilled Water, each, *a sufficient quantity*. Add enough Chloroform to a convenient quantity of Distilled Water, contained in a dark amber-colored bottle, to maintain

a slight excess of the former, after the contents have been repeatedly and thoroughly agitated. When Chloroform Water is required for use, pour off the needed quantity of the solution, refill the bottle with Distilled Water and saturate it by thorough agitation, taking care that there be always an excess of Chloroform present." *U. S.*

"Chloroform, 30 *minims* (Imperial measure) or 2·5 cubic centimetres; Distilled Water, sufficient to produce 25 *fluid ounces* (Imp. meas.) or 1000 cubic centimetres. Shake them together until the Chloroform is dissolved." *Br.*

This water contains one-half per cent. of chloroform, and is probably fully saturated. The British preparation contains half the proportion of Chloroform present in the corresponding preparation of the British Pharmacopœia (1885). Chloroform water has been proved to be an excellent vehicle for administering active remedies, and, owing to its antiseptic properties, mixtures having it for a basis resist decomposition longer than those made with ordinary water. The dose is from one-half to two fluidounces (15–60 C.c.).

AQUA CINNAMOMI. U. S., Br. Cinnamon Water.

(Ā'QUĄ CĬN-NĄ-MŌ'MĪ.)

Eau de Cannelle, *Fr.;* Einfaches Zimmtwasser, *G.*

"Oil of Cinnamon, *two cubic centimeters* [or 32 minims]; Precipitated Calcium Phosphate, *four grammes* [or 61 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Cinnamon with the Precipitated Calcium Phosphate, add the Distilled Water gradually, under continued trituration, and filter." *U. S.*

"Cinnamon Bark, bruised, 1 *pound* (Imperial) or 500 grammes; Water, 2 *gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Of these processes, that of the U. S. Pharmacopœia is the easier, though the second, the British, may yield a sweeter product. On standing, cinnamon water is apt to precipitate, owing to the gradual oxidation and formation of cinnamic acid, which is comparatively insoluble in water; this can be prevented, according to E. Backhaus, by passing a stream of carbonic acid through the fresh water for a few minutes. We have never seen the precipitation successfully prevented, notwithstanding the application of numerous so-called preventives; these usually delay the precipitation, but in a few weeks' time the cloudiness due to the formation of minute crystals of cinnamic acid invariably appears. Cinnamon water is much used as a vehicle for other less agreeable medicines, but should be given cautiously in inflammatory affections. For ordinary purposes the U. S. preparation is sufficiently strong when diluted with an equal measure of water. Dr. E. Holmes recommends glycerin as an excellent intermedium between the oil of cinnamon and water. Ten drops of glycerin will effect the solution of a drop of the oil in a fluidounce of water.

AQUA CREOSOTI. U. S. Creosote Water.

(Ā'QUĄ CRĒ-Ǫ-SŌ'TĪ.)

Creasote; Eau créosotée, *Fr.;* Kreosotwasser, *G.*

"Creosote, *ten cubic centimeters* [or 162 minims]; Distilled Water, *nine hundred and ninety cubic centimeters* [or 33 fluidounces, 228 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Agitate the Creosote vigorously with the Distilled Water, and filter through a well-wetted filter." *U. S.*

This preparation contains 1 per cent., or about 4·8 minims, of creosote in each fluidounce, and affords a convenient method of administering that medicine. It is about the same strength as that formerly official. The dose is from one to four fluidrachms (3·69–15 C.c.). It may also be used with advantage as a gargle, a lotion, or mixed with cataplasms, to correct *fetor*, and gently stimulate *indolent surfaces*.

AQUA DESTILLATA. U. S., Br. Distilled Water.

H_2O; 17·96. (Ā'QUĄ DĔS-TĮL-LĀ'TĄ.) H_2O; 18.

"Prepared by distillation from good natural potable water." *Br.*

Eau distillée, Hydrolat simple, *Fr.;* Destillirtes Wasser, *G.*

"Water, *one thousand volumes* [or 33 fluidounces, 6½ fluidrachms], To make *eight hundred volumes* [or about 27 fluidounces]. Distil the Water from a suitable apparatus provided with a block-tin or glass condenser. Collect the first *one hundred volumes* [or 3¼ fluidounces], and

throw this portion away. Then collect *eight hundred volumes* [or 27 fluidounces], and keep the Distilled Water in glass-stoppered bottles, rinsed with hot distilled water immediately before being filled." *U. S.*

No natural water is sufficiently pure for certain pharmaceutical purposes; and hence the necessity of the above processes for its distillation. It is best to reject the first portion which comes over, as this may contain carbonic acid and other volatile impurities; and the last portion of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The distillation is usually performed with the ordinary still and worm; but, to avoid any impurity from the worm or the receiver, the condenser is directed in the U. S. Pharmacopœia to be of block tin or glass. Mr. Brande states that distilled water often derives from the still a foreign flavor, which it is difficult to avoid. He therefore recommends that a still and condenser be kept exclusively for distilling water; or, where this cannot be done, that steam be driven through the worm for half an hour, for the purpose of steaming it out, before it is used, the worm-tub having been previously emptied. J. N. Hurty prefers well water as the source of distilled water, and that it be boiled before collecting the distillate, to get rid of ammonia, and, to prevent access and growth of spores, that the water be heated to boiling before introducing it into the container, and that it be drawn off by a siphon-tube reaching to the bottom of the vessel, the mouth of which is loosely stopped with cotton. (*Western Druggist*, 1887, p. 4.) Even the use of pure tin, which is generally considered unexceptionable, does not give perfect security against impurity, as water distilled from metallic alembics with the head and worm of this metal has a peculiar odor which it retains for some time. Ordinary distilled water invariably contains ammonia, as may be proved by adding a few drops of Nessler's reagent. (See p. 198.) In order to free distilled water from volatile nitrogenous bodies, it is necessary to redistil it after it has been placed in contact with potassium permanganate and caustic potash. After about one-twentieth of the water has come over, the distillate is usually free from ammonia, and leaves no residue on evaporation. If traces of ammonia remain, acid potassium sulphate is added, and it is redistilled. (*Stas.*)

Properties, etc. Distilled water, as usually obtained, has a vapid and disagreeable taste, and is not perfectly pure; water, to be rendered so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua*. Distilled water should undergo no change by hydrogen sulphide, or on the addition of tincture of soap, lead subacetate, barium chloride, ammonium oxalate, silver nitrate, or lime water. "The transparency of Distilled Water should not be affected, nor should any color be imparted to it, by test-solutions of hydrogen sulphide or ammonium sulphide (absence of *metallic impurities*), or by those of barium chloride (*sulphates*), silver nitrate (*chlorides*), ammonium oxalate (*calcium*), or mercuric chloride (*ammonia*); nor should its transparency be affected when mixed with twice its volume of calcium hydrate test-solution (absence of *carbonic acid*). It should give no reaction for nitrates or nitrites when tested as described under Water (see *Aqua*). When 1000 C.c. of Distilled Water are evaporated on a water-bath to dryness, *no residue* should remain. On heating 100 C.c. of Distilled Water, acidulated with 10 C.c. of diluted sulphuric acid, to boiling, and subsequently adding 1 C.c. of potassium permanganate centinormal volumetric solution, the color of the liquid should not be completely destroyed by boiling for ten minutes, nor by afterwards setting the vessel aside, well covered, for ten hours (absence of *organic* or *other oxidizable matters*)." *U. S.* It is uselessly employed in some formulas, but is essential in others. The British Pharmacopœia requires distilled water to be "Colorless, tasteless, and odorless. 25 cubic centimetres evaporated in a platinum capsule should leave at most a scarcely visible residue (absence of dissolved solids). It should yield no reaction with the tests for the various metals, chlorides, nitrates, nitrites, or sulphates. It should not affect *litmus paper* (absence of acid or alkaline matter). The liquid obtained on boiling 100 cubic centimetres for three minutes with 1·0 cubic centimetre of *diluted sulphuric acid* and 0·1 cubic centimetre of a mixture of one part of *solution of potassium permanganate* and two parts of *water*, should retain its color for one hour (absence of more than traces of organic matter). 100 cubic centimetres mixed with 2 cubic centimetres of *solution of potassio-mercuric iodide*, should not afford a yellow tint more intense than that given by 0·25 cubic centimetre of *solution of ammonium chloride* (*Nessler's*) diluted with 50,000 cubic centimetres of ammonia-free *water* when viewed, under similar conditions, in a glass tube having a diameter of one inch (25 millimetres) (absence of more than 0·005 part of ammonia per million parts)." As a rule, when small quantities of active medicines are to be given in solution, and in the preparation of collyria, distilled water should be directed. The following list contains the chief

substances which require distilled water as a solvent: tartar emetic, corrosive sublimate, silver nitrate, barium and calcium chlorides, lead acetate and subacetate, potassium permanganate, iron and zinc sulphates, quinine sulphate, morphine sulphate, hydrochlorate, and acetate, and, in general terms, all the alkaloids and their salts. Distilled water is used in preparing the official diluted acids, for absorbing gaseous ammonia, and for forming nearly all the official aqueous solutions.

AQUA FŒNICULI. U. S., Br. Fennel Water.

(Ā'QUẠ FŒ-NĬC'Ŭ-LĪ.)

Eau de Fenouil, *Fr.;* **Fenchelwasser**, *G.*

"Oil of Fennel, *two cubic centimeters* [or 32 minims]; Precipitated Calcium Phosphate, *four grammes* [or 62 grains]; Distilled Water, *a sufficient quantity*. To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Fennel with the Precipitated Calcium Phosphate, add the Distilled Water gradually, under continued trituration, and filter." *U. S.*

"Fennel Fruit, 1 *pound* (Imperial) or 500 grammes; Water, 2 *gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Fennel water is a pleasant vehicle for other medicines, and useful when a mild aromatic is indicated. The process of the British Pharmacopœia, although more troublesome, furnishes a more delicate and agreeable water than does that of the U. S. Pharmacopœia.

AQUA HYDROGENII DIOXIDI. U. S. (Br.) Solution of Hydrogen Dioxide. [Solution of Hydrogen Peroxide.]

(Ā'QUẠ HĬ-DRŌ-GĒ'NĮ-Ī DĪ-ŎX'Į-DĪ.)

"A slightly acid, aqueous solution of Hydrogen Dioxide [$H_2O_2 = 33{\cdot}92$], containing, when freshly prepared, about 3 per cent., by weight, of the pure Dioxide, corresponding to about 10 volumes of available oxygen." *U. S.* "An aqueous solution of hydrogen peroxide, H_2O_2, prepared by the interaction of water, barium peroxide, and a dilute mineral acid, at a temperature below 50° F. (10° C.)." *Br.*

Liquor Hydrogenii Peroxidi, *Br.*, **Solution of Hydrogen Peroxide; Oxygenized Water, Oxygen Hydrate; Péroxide d'hydrogène**, *Fr.;* **Wasserstoff Hyperoxyd**, *G.*

"Barium Dioxide, *three hundred grammes* [or 10 ounces av., 255 grains]; Phosphoric Acid, Diluted Sulphuric Acid, Distilled Water, each, *a sufficient quantity*. Pour *five hundred cubic centimeters* [or 16 fluidounces] of cold Distilled Water into a suitable bottle, add to it the Barium Dioxide in such a way that it shall not form lumps, and shake vigorously so that a uniform mixture may result. Provide suitable means of refrigeration, so that the bottle and contents may be kept at a temperature below 10° C. (50° F.), and shake it thoroughly every few minutes during half an hour. Afterwards, continuing the refrigeration, shake it occasionally, but vigorously, until the Dioxide has become fully hydrated, which may be recognized from the fact that only a small portion of the water separates from it on standing, and that it may be mixed with the separated water without great effort by shaking. Having introduced *ninety-six cubic centimeters* [or 3 fluidounces, 118 minims] of Phosphoric Acid into a bottle having the capacity of about *two thousand cubic centimeters* [or 4 pints], add to it *three hundred and twenty cubic centimeters* [or 10½ fluidounces] of Distilled Water, cool the mixture, and remove *fifty cubic centimeters* [or 1 fluidounce, 331 minims] as a reserved portion. Now add the well-mixed magma, in about four portions, to the acid liquid, and mix them intimately by vigorous and continuous shaking, cooling the bottle after each addition of magma. From time to time test the reaction of the liquid, and, when it becomes alkaline, add to it, cautiously, a little of the reserved Phosphoric Acid, until the liquid has again acquired an acid character. Repeat the agitation from time to time, and also the cautious addition of Phosphoric Acid, as long as the liquid becomes alkaline on prolonged, vigorous shaking. If necessary, a further quantity of Phosphoric Acid should be diluted with Distilled Water, in the proportion above given, and a portion of this liquid used for saturation. Having finally shaken the bottle again very thoroughly, and until the liquid part is neutral to litmus paper, set it aside until the precipitate occupies only about one-third of the volume of the contents, and pour the supernatant liquid upon a wetted, double, rapidly-acting, white filter, of a diameter of thirty centimeters [or 12 inches]. Then transfer the semi-liquid precipitate to the filter, rinse the bottle with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Distilled Water, transfer this to the filter, and when the liquid has drained off, wash the barium phosphate on the filter with Dis-

tilled Water, until the filtrate measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Now add to it, first, *twenty drops*, and afterwards, if necessary, further, smaller quantities of Diluted Sulphuric Acid, until a small portion of the liquid, after filtration (which may be assisted by a little starch), is no longer rendered cloudy by Diluted Sulphuric Acid. Mix the cloudy liquid with about *ten grammes* [or 154 grains] of starch by agitation, so that the starch may be thoroughly distributed throughout the liquid, and then filter it through a well-wetted, white filter of a diameter of twenty-five centimeters [or ten inches], returning the first portions until it runs through clear. When all the liquid has passed, ascertain the percentage of Hydrogen Dioxide contained in it by the method of assay given below, and dilute the remaining liquid if necessary, so that it will contain 3 per cent. of absolute Hydrogen Dioxide. Keep the product in loosely-stoppered bottles, in a cool place. Since Solution of Hydrogen Dioxide will gradually diminish in strength, even when carefully kept, it should either be freshly made when wanted, or be kept on hand only in such quantity as will probably be consumed within a short time. Any Solution which has become weaker need not, for this reason, be thrown away, but may be reserved for an occasion when a weaker or diluted solution is prescribed or demanded. Or it may be employed, when making a fresh supply, as a diluent of the stronger solution." *U. S.*

The extended use of this preparation, which was discovered by Thenard in 1818, has earned for it a place in the U. S. Pharmacopœia of 1890. It consists of water in which, by the presenting to it of oxygen in a nascent state, an additional atom of this element has combined with the hydrogen, forming the dioxide, $(HO)_2$, or H_2O_2.

The official process consists in the decomposition of barium dioxide by phosphoric acid, barium phosphate being thrown down as a precipitate, hydrogen dioxide being found dissolved in the supernatant aqueous liquid; the barium phosphate is filtered out, and any trace of barium salt is finally removed by the cautious addition of sulphuric acid, which precipitates as insoluble barium sulphate; the very fine precipitate which usually passes through the pores of filter-paper is caught and held on the filter by the starch, and the clear solution is adjusted to contain 3 per cent., *by weight*, of absolute hydrogen dioxide by the official assay, which follows.

Valuation of Solution of Hydrogen Dioxide. Dilute 10 C.c. of the Solution with water to make 100 C.c. Transfer 17 C.c. of this liquid (containing 1·7 C.c. of the Solution) to a beaker, add 5 C.c. of diluted sulphuric acid, and then, from a burette, potassium permanganate decinormal volumetric solution, until the liquid just retains a faint pink tint after being stirred. Each C.c. of the potassium permanganate decinormal volumetric solution corresponds to 0·0017 Gm. of absolute Hydrogen Dioxide. To express the strength of any Solution of Hydrogen Dioxide approximately in *volumes of available oxygen* (that is, in volumes of oxygen, given off by 1 volume of the Solution upon decomposition), multiply the number of C.c. of permanganate decinormal volumetric solution decolorized by 1 C.c. of the Solution, by 0·56 (0·5594); or those decolorized by 1·7 C.c. of the Solution, by 0·33. (It is assumed that 1000 C.c. of oxygen, at 0° C. (32° F.) and 760 Mm. pressure, weigh 1·43 Gm.) To express the strength in *percentage (by weight) of absolute Hydrogen Dioxide*, multiply the number of C.c. of permanganate decinormal volumetric solution decolorized by 1 C.c. of it, by 0·17; or divide the number of C.c. of permanganate volumetric solution decolorized by 1·7 C.c. of it, by 10.

For another method of preparing this Solution, see U. S. D., sixteenth edition, page 1887. According to Crismer, a pure solution may be made by dissolving barium peroxide in a slight excess of diluted hydrochloric acid (sp. gr. 1·10), and shaking the solution with an equal volume of ether. The ethereal layer is separated and shaken with a little water, which will take up most of the hydrogen peroxide, after the separation of which the ether is again shaken with the above separated solution of barium peroxide, and then with water as before. These operations are repeated five or six times. It is possible in this way to obtain solutions containing from 0·8 to 0·9 per cent. of the peroxide, which are perfectly neutral and free from foreign substances. (*Bull. Soc. Chim.*, 1891, 24.) The official Solution is strong enough for most practical uses, for, although it can readily be made stronger, the difficulties of preserving it largely increase with its increased strength, and hence the Committee of Revision wisely fixed the standard at *ten volumes of available oxygen*. The British Pharmacopœia requires that the Solution shall indicate a yield of from *nine to eleven volumes* of oxygen when tested by the nitrometer test. (See page 216.)

Properties. Solution of hydrogen dioxide was prepared by Regnault in a nearly pure state. As thus procured, it is a colorless liquid of a fluid consistence, of the sp. gr. 1·452,

remaining liquid at zero, beginning to give out oxygen when heated above 15·5° C. (60° F.), and at a higher heat rapidly and sometimes explosively resolved into water and oxygen. But when diluted with water, with which it unites in all proportions,* it is not decomposed under 37·7° C. (100° F.). It may be evaporated *in vacuo* at a gradually increasing temperature, a nearly pure hydrogen dioxide coming over at about 84° C. Wolffenstein states that he has prepared, after repeated fractioning, hydrogen peroxide (99·1 per cent.). (See *Ber. d. Chem. Ges.*, 1894, 3307. See also Schiloff's process, *Chem. News*, 1896, 38.) The great facility with which it parts with oxygen renders it a powerful oxidizer; and the simple contact with various substances, as platinum, gold, and silver, causes it to be resolved into oxygen and water. On the contrary, certain other substances, even though ordinarily evincing a strong affinity for oxygen, as phosphorus, for example, are unaffected by it, and there are a number of bodies which have the property not only of being unaffected by it, but of restraining its oxidizing influence on other bodies, whilst some salts, like silver oxide, are actually reduced by it. Traces of impurities modify the stability of hydrogen dioxide; acids increase, alkalies decrease, its stability.

The official Solution is described as "a colorless liquid, without odor, slightly acidulous to the taste, and producing a peculiar sensation and soapy froth in the mouth; liable to deteriorate by age, exposure to heat, or protracted agitation. Specific gravity, about 1·006 to 1·012 at 15° C. (59° F.). When exposed to the air at the ordinary temperature, or when heated on a water-bath at a temperature not exceeding 60° C. (140° F.), the solution loses chiefly water. When rapidly heated, it is liable to decompose suddenly. Solution of Hydrogen Dioxide has an acid reaction due to a small amount of free acid purposely allowed to remain in it for preservation. On adding to 10 C.c. of water, in a test-tube, 1 drop of potassium chromate test-solution, then 10 drops of diluted sulphuric acid, and pouring a few C.c. of ether on top, the subsequent addition of a few drops of Solution of Hydrogen Dioxide, even when considerably diluted, will cause a blue color to appear at the zone of contact of the two liquids. After shaking, the ethereal layer will separate with a blue color. Upon evaporating 50 C.c. of the Solution to dryness, on a water-bath, not more than 0·25 Gm. of residue should remain. Upon evaporating 50 C.c. of the Solution, previously rendered alkaline by sodium hydrate test-solution, to dryness, transferring the dry residue to a watch-glass, moistening it with sulphuric acid, and setting the glass in a moderately warm place for a few hours, the surface of the glass, after being washed, should exhibit no sign of corrosion (absence of *hydrofluoric acid*). 50 C.c. of the Solution should not require more than 0·5 C.c. of potassium hydrate volumetric solution to render the liquid alkaline, phenolphtalein being used as indicator (limit of *free acid*). The addition of a few drops of diluted sulphuric acid to 10 C.c. of the Solution should produce no turbidity or precipitate (absence of *barium*.)" *U. S.* "On adding a few drops to 8 or 10 cubic centimetres of water containing a drop of solution of potassium chromate, 10 drops of diluted sulphuric acid, and 2 or 3 cubic centimetres of ether, a blue layer will appear between the ethereal and aqueous liquids, and, after agitation, the ether will also become blue. 1 volume, treated in a brine-charged nitrometer with 10 or 12 times its bulk of a mixture of 1 volume of sulphuric acid, 2 volumes of a 5 per cent. solution of potassium permanganate, and 7 volumes of water, should afford, at normal temperature and pressure, not less than 18 and not more than 22 volumes of oxygen, indicating a yield of 9 to 11 volumes from the Solution of Hydrogen Peroxide. It should give no characteristic reaction with the tests for barium. Evaporated to dryness on a water-bath, not more than 0.5 per cent. of solid residue should remain." *Br.* Charles Rice suggests improvements in the method of assay which are practical (see *Amer. Drug.*, 1892, 30). F. X. Moerk has proposed a rapid and effective method of assaying this solution (see *A. J. P.*, 1893, 65); J. F. Brown confirmed the value of Moerk's method (*P. J. Tr.*, 1896, 271). *Solution of hydrogen dioxide should be kept in a cool place, and not too tightly stoppered.* Neglect of these precautions, particularly in hot weather, will be likely to result in an explosion and fracture of the bottle containing it, due to a brisk evolution of oxygen in a confined space, on account of the increased temperature.

Medical Properties and Uses. Many years ago, Dr. B. W. Richardson, of London, pointed out that hydrogen peroxide is a powerful physiological agent, which when brought in contact with most animal tissues, or with sugar or starch, acts as an oxidizant. He stated

* *Ozonic ether* is a name proposed for a solution of hydrogen peroxide in ether, which was first noticed by Dr. Richardson. Ether will take a portion of the peroxide from its watery solution, forming a compound of considerable stability, as it has borne a voyage to Australia without change. Care, however, must be taken to guard against the consequences of its extreme inflammability. (See *A. J. P.*, 1869, p. 156.)

that when injected into the left cavity of the heart of an animal it restores recently-lost irritability, but that it has an opposite effect in the right cavity; also, that when thrown into the artery immediately after death it restores for a time the contractile power of the muscles, and suspends cadaveric rigidity. It does not, however, seem to be of value for affecting the general system, as it was found in the experiments of Dr. H. C. Wood to coagulate blood so rapidly when put into the blood-vessel that it does not seem possible for it to find entrance into the blood. Nevertheless it has been used internally in low *fevers* and *whooping-cough*, and various other diseases, and has been strongly lauded by Dr. John Day (*London Lancet*, Jan. 1868) and others as a positive cure in *diabetes*. Further experience has demonstrated, however, its inutility in *glycosuria*. It is extremely improbable that any of the peroxide can find its way into the system when its solutions are given by the mouth, as it would certainly destroy itself by acting upon the organic contents and secretions of the gastro-intestinal tract.

When hydrogen peroxide is brought in contact with mucous membranes or ulcerated surfaces, albuminous coagulation is immediate, with the formation of a white coating and a rapid evolution of gas. It is a very powerful antiseptic, which has been found by various experimenters, especially Dr. Pane (*Lond. Med. Rec.*, Jan. 1891) to be extremely poisonous to pathogenic germs. The conclusions of Dr. Pane were that (1) Hydrogen peroxide in a solution of 1 to 100 has an energetic disinfecting power. (2) The solution 1 to 1000 is a weak antiseptic, and inferior to the corresponding solution of corrosive sublimate. The solution of H_2O_2, in nutritive substances, 1 to 352, not only impedes the development but after some days kills the spores of the bacillus of charbon. (3) The solution of H_2O_2, in nutritive substances, from 1 to 352 to 5052, impedes the development of the spores of the bacilli of charbon, but does not deprive them of their germinative power when they are transferred to another nutritive substance. Thus, oxygenated water in nutritive substances has a more powerful action on the spores of the bacillus of charbon than has corrosive sublimate, since the spores can develop freely in a solution of gelatin of 1 to 1000 of the mercurial.

On account of its oxidizing properties, it is a powerful deodorant, rapidly destroying hydrogen sulphide and similar gases. When hydrogen peroxide is brought in contact with pus, rapid change occurs, with evolution of oxygen gas, and Dr. Pane found under the microscope that so soon as charged with gas the corpuscles become granular, lose their form, and break up into detritus.

Its liquid form makes it especially adapted for putrid cavities and abscesses, which it will thoroughly cleanse. It cannot, however, take the place of such antiseptics as mercuric chloride, because its influence is so immediate and fugacious. As a preventive antiseptic it is of little value. For disinfecting the hands and instruments of the surgeon it has the great advantage of immediate and powerful action, and of not staining the hands or clothing. By some surgeons it is said not to affect the instruments.

As a local application in specific *inflammations of mucous membranes* hydrogen peroxide is of greatest value. In *scarlet fever* and *diphtheria* the official solution may be applied by mop to the pharynx, often with extraordinarily good results. Diluted one-half, it may be injected into the nasal cavities when they are affected. Injection of a solution of from 20 per cent. to full strength has received commendation in the treatment of *gonorrhœa* and *chancre*. The official solution has also been used with alleged great success as a local styptic. It is probably for practical purposes free from poisonous properties. The fatal results which Dr. Pane produced by injecting the strong solution directly into the peritoneal cavity of the rabbit being, in all probability, due to the shock produced by the intense local irritation of the peritoneum. Death from shock also affords the most plausible explanation of the case reported by Dr. Laach (*Lancet*, Oct. 1886), in which six injections into the pleural cavity, each containing 0·8 cubic centimeter of a 3-per-cent. solution of hydrogen peroxide, were administered, but at the seventh the patient complained of faintness, the pulse failed, respiration became oppressed, and death occurred in ten minutes. As a local application to mucous membranes, the official solution should be used; the stronger solutions are sometimes too irritating.

Solution of hydrogen dioxide has come to be a common commercial preparation in 10- or 15-per-cent. aqueous solutions. It is used for the purpose of cleaning and bleaching old and stained engravings and oil paintings. The dioxide has also been used as an auricome for bleaching dark-colored hair. It is employed, moreover, in increasing degree in the textile industries for bleaching. Lunge has proposed its use in the ready valuation of chlorinated lime or bleaching powder, which is decomposed by it with the simultaneous liberation of oxygen from

both substances in equal amount. It has been detected by M. Struvé, of St. Petersburg, in minute proportion, in the air of the atmosphere in Southern Russia. (*Chem. News*, July 2, 1869, p. 23.) Schönbein has made the same discovery in the vicinity of Basel, in Switzerland. In both instances it was found in the rain water. (*Neues Repertorium*, 1869, xviii. 364.)

AQUA LAURO-CERASI. Br. Cherry-Laurel Water.

(Ā'QUẠ LÂU'RŌ–ÇĔR'Ạ-SĪ.)

Eau distillée de Laurier-cerise, *Fr.*; Kirschlorbeerwasser, *G.*

"Fresh Cherry-Laurel Leaves, 1 *pound* (Imperial) or 320 grammes; Water, 2½ *pints* (Imp. meas.) or 1000 cubic centimetres. Place the crushed Cherry-Laurel Leaves with the water in a retort; distil one pint (or four hundred cubic centimetres) of liquid; shake the product; filter, if necessary; adjust the strength of the finished product either by adding hydrocyanic acid or by diluting the distillate with Distilled Water, so that, when tested as described under 'Acidum Hydrocyanicum Dilutum,' it shall contain one-tenth per cent. of hydrocyanic acid, HCN." *Br.*

It is greatly to be regretted that this uncertain, dangerous, and troublesome preparation should retain its place in European pharmacopœias, inasmuch as it could easily be replaced by a flavored water containing a definite amount of a soluble cyanide.

As the cherry-laurel is little cultivated in the United States, the Water is not official; but from experiments by the late Prof. Procter there is little or no room to doubt that a preparation identical in its effects might be made from the leaves of our common wild cherry, *Cerasus serotina*. The imported cherry-laurel water, as found in commerce, is generally impaired by age, and not to be relied on.

A. Ripping, of Rotterdam, proposes to make an artificial cherry-laurel water by adding 6 grammes of oil of cherry-laurel and 4·5 grammes of potassium cyanide to a half-liter of water, and distilling the mixture in a tubulated retort, a current of carbonic acid gas being passed through it at the same time. The distillate is afterwards diluted with distilled water so as to contain one-tenth per cent. of hydrocyanic acid. (*Archiv d. Pharm.*, 1876, pp. 526–531.)

Cherry-laurel leaves contain 65 per cent. of water, sufficient to provoke the reactions which result in the formation of a volatile oil and hydrocyanic acid. Water is very prone to hasten the conversion of the volatile oil into benzoic acid by oxidation, and it has been found by Mr. C. Umney (*P. J. Tr.*, x. 467) and by Dr. Moore (*Ibid.*, 604) that the water distilled without previous maceration is somewhat stronger in hydrocyanic acid and decidedly stronger in oil (Umney) than the official product. The strength of official cherry-laurel water is so uncertain as to render it ineligible. It ought to be a powerful preparation, about one-twentieth the strength of the official hydrocyanic acid (*Br. Ph.*), and yet in commerce it varies as 53 to 100 (Umney). The difference depends upon the age of the preparation, the mode of preparing, and the time of year at which the leaves are gathered. M. Garot (*Annuaire de Thérap.*, 1843, 45) has found that the leaves yield only half as much in July as in April. Mr. C. Umney obtained 1·26 grains of acid in 1000 grains in March, in July 1·08 grains, and in November 0·64 grains. (*P. J. Tr.*, x. 468.) Dr. Moore, in an elaborate series of experiments, obtained the largest product in July of one year and in October of the next. Mr. Leger (*Ibid.*, June, 1873) has found the maximum percentage in July, and also that different leaves taken from the same bush on the same day vary enormously, young leaves being much richer than old ones. The proportion of hydrocyanic acid in the Water diminishes with time. It has been ascertained by M. Deschamps that if a drop of sulphuric acid be added to a pint of the preparation it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. M. Lepage found that, preserved in full and perfectly air-tight bottles, both this and bitter-almond water remained unchanged at the end of a year; while if freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (*Journ. de Pharm.*, xvi. 346.) In view of the uncertain strength of the Water as obtained from the leaves, it was proposed in France, in reference to the Codex then in preparation, to fix upon a definite proportion of hydrocyanic acid; and the percentage generally adopted was from 0·04 to 0·05.* For Denigés's method of assaying the water, see *Proc. A. P. A.*, 1894, 556. Dr.

* The following conclusions in reference to cherry-laurel water were arrived at by a committee of pharmaceutists in Paris, appointed to examine the subject of the distilled waters with a view to the revision of the Codex. 1. The whole of the volatile oil and hydrocyanic acid furnished by cherry-laurel leaves results from a reaction between two substances analogous to the emulsin and amygdalin of bitter almonds, which can take place only in the

W. H. Pile proposed an easy volumetric method for estimating the hydrocyanic acid strength of cherry-laurel and bitter-almond waters, as well as of other liquids containing this acid. (See *A. J. P.*, 1862, 130.)

Medical Properties. Cherry-laurel water is employed in Europe as a sedative narcotic, identical in its properties with a dilute solution of hydrocyanic acid; but it is of uncertain strength, and should not be allowed to supersede the more definite preparation of the acid now in use. Its fraudulent use in Paris in the preparation of a cordial, in imitation of the genuine cherry cordial, made by fermentation and distillation, and like it called "*kirsch*," has been the subject of no little reprobation. (*Journ. de Pharm. et de Chim.*, 4e sér., i. 33, 1865.) The dose is from thirty minims to a fluidrachm (1·9–3·7 C.c.)

AQUA MENTHÆ PIPERITÆ. U. S., Br. Peppermint Water.

(Ā'QUA MĔN'THÆ PĪ-PĔ-RĪ'TÆ.)

Eau de Menthe poivrée, *Fr.*; Pfefferminzwasser, *G.*

"Oil of Peppermint, *two cubic centimeters* [or 32 minims]; Precipitated Calcium Phosphate, *four grammes* [or 62 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Peppermint with the Precipitated Calcium Phosphate, add the Distilled Water gradually, under constant trituration, and filter." *U. S.*

"Oil of Peppermint, 77 *minims* (Imperial measure) or 10 cubic centimetres; Water, 1½ *gallons* (Imp. meas.) or 15 litres. Distil two-thirds." *Br.*

AQUA MENTHÆ VIRIDIS. U. S., Br. Spearmint Water.

(Ā'QUA MĔN'THÆ VĪR'Ĭ-DĬS.)

Eau de Menthe verte, *Fr.*

"Oil of Spearmint, *two cubic centimeters* [or 32 minims]; Precipitated Calcium Phosphate, *four grammes* [or 62 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Spearmint with the Precipitated Calcium Phosphate, add the Distilled Water gradually, under constant trituration, and filter." *U. S.*

"Oil of Spearmint, 77 *minims* (Imperial measure) or 10 cubic centimetres; Water, 1½ *gallons* (Imp. meas.) or 15 litres. Distil two-thirds." *Br.*

There would seem to be no good reason for distilling the mint waters from their respective volatile oils, as directed in the British processes. If the fresh plants were available, a good source for a distilled water could be provided; but if a volatile oil must be used, with its uncertainty of freshness always present, the quicker process of the U. S. Pharm. is greatly preferable.

The two mint waters are among the most grateful and most employed of this class of preparations. Together with cinnamon water, they are used in this country, almost to the exclusion of all others, as the vehicle of medicines given in the form of mixture. They serve not only to conceal or qualify the taste of other medicines, but also to counteract their nauseating properties. Peppermint water is generally thought to have a more agreeable flavor than that of spearmint, but some prefer the latter. Their effects are the same.

presence of water. 2. The quantity of volatile oil furnished by the leaves is always in direct relation to that of hydrocyanic acid. 3. The leaves furnish, by mere contact for twenty-four hours with cold water, only one-third of the quantity which they can be made to yield. 4. The fermentable matter of the leaves is liable to change, so that the leaves, after being picked, afford less and less of the acid the longer they are kept; and a moist heat favors change, so that complete decomposition takes place in a few hours. 5. Difference in climate, soil, exposure to the sun, and age of the tree, have but a secondary influence on the productiveness of the leaves. 6. The season of the year, however, has a great influence. The younger the leaf, the greater is its yield; so that, while 0·150 per cent. of the acid was obtained from the forming leaves in spring, those of the autumn yielded only 0·132, those of the winter 0·120, and leaves two years old gave only 0·112. 7. Different plants, under apparently the same circumstances, differ greatly in productiveness, so that 0·176 per cent. was obtained from the most productive, and only 0·092 from the least so. 8. The distillation by steam yields the greatest possible product. The committee, therefore, propose the adoption of this method, the bruised leaves having been previously mixed with at least three times their weight of water, and exposed to a gradually increasing heat, not to exceed 140° F., when all reaction ceases. 9. Bruising is the best method of comminuting the leaves. 10. As it is impossible to obtain a Water always identical from the leaves, the committee propose to fix a definite strength, and state that the proportion generally adopted is from 0·040 per cent. of acid as the minimum to 0·050 or one-twentieth of one per cent. as the maximum, which is only one-half the strength proposed for bitter-almond water. 11. Though a change rapidly takes place in this and bitter-almond water exposed to the air, yet in bottles full, and perfectly closed by glass stoppers, the change at the end of a year is scarcely perceptible; and this observation applies to the distilled waters in general. (*Journ. de Pharm.*, 1864, p. 520.)

AQUA PIMENTÆ. Br. Pimento Water.

(Ā'QUA PĪ-MĔN'TÆ.)

"Pimento, bruised, 8 *ounces* (Imperial) or 250 grammes; Water, 2 *gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Pimento water is an agreeable aromatic water, used as a vehicle.

AQUA ROSÆ. U. S., Br. Rose Water.

(Ā'QUA RŌ'ŞÆ.)

Eau distillée de Rose, *Fr.;* Rosenwasser, *G.*

"Stronger Rose Water, Distilled Water, of each, *one volume* [or 1 pint]. Mix them immediately before use." *U. S.* "The rose water of commerce,* prepared by distillation from the flowers of Rosa damascena, Linn., diluted, immediately before use, with twice its volume of Distilled Water." *Br.*

The British Pharmacopœia of 1898 abandoned the former process of distilling the leaves and followed the method adopted by the U. S. Pharmacopœia of diluting the so-called triple rose water of commerce with distilled water. This, however, does not make rose water identical in strength in these authorities, the U. S. preparation being about 17 per cent. the stronger.

Although domestic rose water of fair quality may be made by distilling fresh rose petals, it does not possess the strength or delicacy of the by-product obtained from abroad, as officially described under *Aqua Rosæ Fortior;* hence the above process of diluting this stronger rose water. The process of distilling the fresh petals of the hundred-leaved rose is sometimes practised. These are usually preferred in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odor, and afford a water equally fragrant with that prepared from the fresh flowers. Indeed, Mr. Haselden prefers the salted roses, believing that the water prepared from them is less mucilaginous, less apt to become sour, and keeps its odor better than that prepared from the fresh flowers. (*P. J. Tr.*, xvi. 15.) It is not uncommon to employ the whole flower, including the calyx; but the product is less fragrant than when the petals only are used, as officially directed.† Rose water is sometimes made by distilling together water and the oil of rose. This is best performed by dropping 10 drops of oil of rose on a sponge and adjusting it in the upper part of a still in the body of which a gallon of water is placed: the steam from the boiling water will carry over portions of the oil, and the distillate will thus be impregnated.

When properly prepared, it has the delightful perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters, it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second dis-

* "The rose water of commerce is a saturated solution of the essential oil of the rose flowers." *Br.*

† A. Monthus states that the petals of the hundred-leaved rose are more odorous the nearer they are to the centre of the flower, and, contrary to what is said in the text, thinks that the calyx should not be rejected in preparing the distilled water. He maintains that so far from injuring the product it in fact contributes to its preservation, and that the water obtained from the whole flower is less liable to that mucosity which is the commencement of decomposition. This effect he ascribes to the astringent matter of the calyx, coagulating the mucilaginous matter of the petals, and preventing it from passing over in the distillation. (*Journ. de Pharm.*, 1863, p. 497.)

Milk of Roses. In making this cosmetic it is essential to produce an emulsion which, if it separates after long repose, may be restored by slight agitation. Although other perfumes may be, and are, commonly added to it, the scent of roses should predominate and form its characteristic odor. There are three varieties, the English, French, and German. The latter variety should never be employed as a cosmetic, on account of its containing lead.

English. Almonds (blanched) 1½ ounces; Oil of Almonds and White Windsor Soap, of each, 1 drachm; Rose Water ⅔ pint. Make an emulsion; to the strained emulsion add a mixture of Essence or Spirit of Roses ½ fluidrachm: Alcohol 2½ fluidounces; and subsequently of Rose Water q. s. to make the whole measure one pint; more alcohol is apt to cause the separation of the ingredients. Some makers add a few drops of oil of bergamot, with two or three drops each of oil of lavender and otto of roses, dissolved in the alcohol.

Or, Oil of Almonds and White Windsor Soap, of each, 1 ounce: Salts of Tartar ½ drachm; Boiling Water ½ pint. Triturate, and subsequently agitate until perfectly united. When cold, further add Alcohol 2 fluidounces; Spirit of Roses a few drops; Rose Water q. s. to make the whole measure a pint.

French. Tincture of Benzoin (simple) ½ fluidounce; Tincture of Styrax ½ fluidounce; Spirit of Roses 1 to 2 fluidrachms; Alcohol 2½ fluidounces. Mix, and add gradually, with agitation, Rose Water 16½ fluidounces. Augustin recommends the addition of a little potassium carbonate (say 1 drachm to the pint) when it is intended to be used as a lotion in acne.

Or, Tincture of Benzoin (simple) 1 fluidrachm; Tincture of Balsam of Peru 20 drops; Rose Water ½ pint. The addition of an ounce of alcohol, in lieu of a like quantity of rose water, improves it.

German. Dilute solution of Lead Diacetate, ½ fluidounce; Lavender Water 2 fluidrachms; Alcohol 2½ fluidounces; Rose Water ¾ of a pint. Mix and agitate.

tillation. This distilled water is chiefly employed, on account of its agreeable odor, in collyria and other lotions. It is wholly destitute of irritating properties, unless it contain alcohol.

AQUA ROSÆ FORTIOR. U. S. Stronger Rose Water. [Triple Rose Water.]

(Ā'QUẠ RŌ'ṢÆ FÖR'TI-ỌR.)

Aqua Rosæ, *U. S.* 1880.

"Water saturated with the volatile oil of Rose petals, obtained as a by-product in the distillation of Oil of Rose. Stronger Rose Water should be kept in well-stoppered bottles, in a dark place." *U. S.*

This has been introduced for the purpose of making rose water. (See article next above.)

"Stronger Rose Water should be colorless and clear, not mucilaginous, and give no reaction with hydrogen sulphide or ammonium sulphide test-solution (absence of *metallic impurities*)." *U. S.*

AQUA SAMBUCI. Br. Elder-Flower Water.

(Ā'QUẠ SĂM-BŪ'CĪ.)

"Fresh Elder Flowers, 10 *pounds* (Imperial) or 5000 grammes (or an equivalent quantity of the flowers preserved, while fresh, with common salt); Water, 5 *gallons* (Imp. meas.) or 25 litres. Distil one-fifth." *Br.*

Elder flowers yield very little oil upon distillation; and, if the water be needed, it may be best prepared from the flowers. Mr. Haselden prefers the salted flowers to the fresh, for the reason stated under Rose Water. The preparation is little used in this country.

ARAROBA. Br.

(ĂR-Ạ-RŌ'BẠ.)

"A substance found in cavities in the trunk of Andira Araroba, Aguiar, freed as much as possible from fragments of wood, dried, and powdered." *Br.*

Crude Chrysarobin, Goa Powder, Poh di Bahia; Poudre de Goa, *Fr.;* **Goa-Pulver,** *G.*

Under the name of Chrysarobin, or Araroba, there has long been used a medicine in Brazil, and exported in considerable quantities to Portugal, whence it found its way through the Portuguese colonies into Eastern commerce. In the East Indies it is usually known as Goa Powder. Indeed, the identity of the two powders was first proved in 1875 by Dr. J. F. Dasilva Lima. (*P. J. Tr.*, v.) It has been supposed to be yielded by certain lichens, but was shown by Dr. R. A. Monteiro to be obtained from a leguminous tree abundant in the forests of the Brazilian province of Bahia, which was referred by Mr. E. M. Holmes to the genus Cæsalpinia, but which was determined by studies made in its native forests by Dr. J. M. de Aguiar to be an undescribed Andira.

Andira araroba, Aguiar, is a large tree, attaining a height of 100 feet, with a smooth trunk, and a spheroidal, not very bushy head. The wood is yellowish, with numerous longitudinal canals, besides abundant irregular interspaces or lacunæ, in which the chrysarobin is deposited. (See *P. J. Tr.*, ix. 755; x. 42, 814.) The oldest trees yield the largest amount of the powder; the parts containing it are finely chipped or scraped off. The workmen who procure it often suffer severely from irritation of the eyes and face. As first obtained, chrysarobin is stated to be of a pale primrose yellow, but it rapidly darkens with age, so that in commerce it varies from a dull ochre to a dark chocolate or maroon-brown. It is sometimes a rather fine powder, but is usually more or less agglomerated, and not rarely contains fragments of woody tissue. Its taste is bitter. It is insoluble in water and most menstrua, but yields as much as 80 per cent. of its weight to solutions of caustic alkalies and to benzol. The British Pharmacopœia requires that it should yield to hot *chloroform* not less than 50 per cent. of pure chrysarobin. Attfield analyzed Goa powder, and found, along with 2 per cent. of resin, 5·5 per cent. of woody fibre, and 7 per cent. of bitter extractive, from 80 to 84 per cent. of what he considered to be chrysophanic acid; but Liebermann and Siedler showed that this was not chrysophanic acid at all, but a substance easily convertible into the acid, which substance they called *chrysarobin*, and gave to it the formula $C_{30}H_{26}O_7$. (See *Chrysarobinum*, p. 385.)

ARGENTUM.

Ag; 108. (ĂR-ĢĔN'TṲM.) **Ag; 108.**

Argent raffiné, Argent, *Fr.;* **Silber, Raffinirtes Silber,** *G.;* **Argento,** *It.;* **Plata,** *Sp.*

Silver is occasionally found in the metallic state, sometimes crystallized, at other times combined with gold, antimony, arsenic, or mercury; but usually it occurs in the state of sulphide,

either pure or mixed with other sulphides, as those of copper, lead, and antimony. It is sometimes found as a chloride.

The most productive mines of silver are found on this continent, being those of Mexico and Peru and our own Rocky Mountain States and Territories; the richest in Europe are those of Norway, Hungary, and Transylvania. Mines have been opened and profitably worked in California and Nevada, but at present it is chiefly Colorado and Montana which furnish the great bulk of the American silver production. Idaho, Utah, and Arizona also contain very rich silver deposits. The principal ore is the sulphide. The mineral containing silver which is most disseminated is argentiferous galena, which is lead sulphide containing a little silver sulphide. Argentiferous galena exists in several localities in the United States. Native silver is associated, in small quantities, with the native copper of the Lake Superior region, and a little of it has come into the market. The two metals, though more or less mixed, are yet quite distinct, never being alloyed to any considerable extent, showing conclusively that the deposits have not undergone igneous fusion at any time, but that the metals have deposited from solution. The production of silver in the United States for 1896 was 58,488,810 troyounces, valued at $39,245,992, and for 1897, 56,457,292 ounces, valued at $33,755,815. The world's production, however, grew from 176,706,718 ounces in 1896, to 179,290,820 ounces in 1897.

Extraction. Silver is extracted from its ores by two principal processes, *amalgamation* and *cupellation*. At Freiberg, in Saxony, the ore, which is principally the sulphide, is mixed with a tenth of sodium chloride and roasted in a reverberatory furnace. As fast as the sulphide is oxidized to sulphate, this reacts with the sodium chloride, forming silver chloride and sodium sulphate. The roasted mass is then reduced to very fine powder, mixed with half its weight of mercury, one-third of its weight of water, and about a seventeenth of iron in flat pieces, and subjected for sixteen or eighteen hours to constant agitation in barrels turned by machinery. The chlorine combines with the iron, and remains in solution as iron chloride; while the reduced silver forms an amalgam with the mercury. The amalgam is then subjected to pressure in leathern bags, through the pores of which the excess of mercury passes, a solid amalgam being left behind. This is then subjected to heat in a distillatory apparatus, by means of which the mercury is separated from the silver, which is left in a porous mass. In Peru and Mexico the process is similar to that above given, common salt and mercury being used; but slaked lime and iron sulphide are also employed, with an effect which is not very obvious.

When argentiferous galenas are worked for the silver they contain, they are at first reduced, and the argentiferous lead obtained is fused on a large, oval, shallow vessel called a *test*, and exposed to the blast of a bellows, whereby the lead is oxidized, half vitrified, and driven off the test in scales, in the form of *litharge*. The operation being continued on successive portions of argentiferous lead, the whole of the lead is separated, and the silver, not being oxidizable, accumulates on the test as a brilliant fused mass, until its amount is sufficient to be removed. The time required for the separation is much abridged by the process of Mr. Pattinson, of Newcastle, England. This consists in allowing the melted alloy to cool slowly, and separating the crystals which first form, consisting mainly of lead, by means of a perforated ladle. The residue is a very fusible alloy of lead and silver, in which the latter metal is in large proportion, and from which it can be easily separated by cupellation or other means.

Properties. Silver is a white metal, very brilliant, tenacious, malleable, and ductile. In malleability and ductility it is inferior only to gold. It is harder than gold, but softer than copper. Its atomic weight is 108, symbol Ag, and sp. gr. from 10·4 to 10·5. It forms but one well-characterized oxide. Exposed to a full red heat, it enters into fusion, and exhibits a brilliant appearance. It is not oxidized in the air, but contracts a superficial tarnish of silver sulphide by the action of hydrogen sulphide in the atmosphere; from which it may be freed by washing it with a strong solution of potassium cyanide, and, as soon as it becomes bright, washing it with water and drying it. (*Chem. News*, 1866, p. 12.) It is entirely soluble in diluted nitric acid. If any gold be present, it will remain undissolved as a dark-colored powder. From the nitric solution the whole of the silver may be thrown down by sodium chloride, as a white precipitate of silver chloride, characterized by being completely soluble in ammonia. If the remaining solution contain copper or lead, it will be precipitated or discolored by hydrogen sulphide. "The solution, deprived of silver by means of sodium chloride, and filtered, is not colored, *or but slightly so*, and is not precipitated by hydrosulphuric acid." *U. S.* 1870. "If ammonia be added in excess to a solution of the metal in nitric acid, the resulting fluid exhibits neither color nor turbidity" (*Br.* 1885); proving the absence of copper,

lead, and other metals. "10 grains dissolved in a little nitric acid, the solution diluted with water, and diluted hydrochloric acid added in slight excess, yields a white precipitate which, when thoroughly washed, dried, and heated, weighs 13·25 grains." *Br.* 1885.

ARGENTI CYANIDUM. U. S. Silver Cyanide.

Ag CN; 133·64. (ĂR-ĢĔN'TĪ CĪ-ĂN'Ị-DŬM.) Ag CN; 133·7.

Cyanuret of Silver; Argentum Cyanatum; Cyanure d'Argent, *Fr.*; Cyansilber, *G.*

A process for preparing this salt is no longer official. Below may be found that of the U. S. P. 1870.*

In the process of 1870 all the silver contained in a given weight of silver nitrate, placed in a receiver in solution, is converted into cyanide by hydrocyanic acid, produced from potassium ferrocyanide by the action of sulphuric acid, $AgNO_3 + HCN = HNO_3 + AgCN$. The materials in the retort are sufficient to produce a little more hydrocyanic acid than is necessary to convert the whole of the silver in the receiver into cyanide; so that the complete decomposition of the silver nitrate is insured. Silver cyanide should be kept in dark amber-colored vials, protected from light.

According to Messrs. Glassford and Napier, the best way of obtaining silver cyanide is to add potassium cyanide to a solution of silver nitrate so long as a precipitate is formed.

Properties. Silver cyanide is "a white powder, without odor or taste, permanent in dry air, but gradually turning brown on exposure to light. Insoluble in water, alcohol, or cold nitric acid, but soluble in boiling nitric acid with evolution of hydrocyanic acid; also soluble in ammonia water and in solution of sodium hyposulphite or of potassium cyanide. When heated, the salt fuses, gives off cyanogen gas, and, on ignition, leaves a residue of metallic silver, amounting to 80·56 per cent. of its original weight." *U. S.*

Its best solvent is potassium cyanide. It has no medical uses, but is official solely for the purpose of making Hydrocyanic Acid.

ARGENTI IODIDUM. U. S. Silver Iodide.

Ag I; 234·19. (ĂR-ĢĔN'TĪ Ī-ŌD'Ị-DŬM.) Ag I; 234·3.

This official salt may be readily prepared by adding a solution of potassium iodide to one of silver nitrate, and washing and drying the precipitate, which should be kept in dark amber-colored vials, protected from light.

According to the experiments of M. Fizeau, it has the remarkable property of contracting with heat and expanding with cold, differing in this respect from the chlorides and bromides of the same metal, and the iodides of other metals. (*Journ. de Pharm.*, 1867, p. 435.) This appears, however, to be only a partial truth, the iodide having three allotropic forms and a point of maximum density at about 116° C. (240·8° F.). See paper by G. F. Rodwell, in *Chem. News*, xx. 288; xxi. 14. The Pharmacopœia describes it as "a heavy, amorphous, light yellowish powder, unaltered by light, if pure, but generally becoming somewhat greenish-yellow, and having neither odor nor taste. Insoluble in water, alcohol, diluted acids, or in solution of ammonium carbonate, but soluble in about 2500 parts of stronger ammonia water. It is also dissolved by an aqueous solution of potassium iodide, and by a concentrated solution of potassium iodide, and the resulting solutions yield a black precipitate with hydrogen sulphide test-solution or ammonium sulphide test-solution. When heated to about 400° C. (752° F.), the salt melts to a dark-red liquid, which, on cooling, congeals to a soft, yellow, slightly transparent mass. When mixed with ammonia water, it turns white, but regains its yellowish color upon being washed with water. If a small quantity of chlorine water be agitated with an excess of the salt, the filtrate acquires a dark-blue color on the addition of starch test-solution. If 0·5 Gm. of the salt be digested for five minutes with 10 C.c. of a cold 15-per-cent. solution of ammonium carbonate, the filtrate, when supersaturated with nitric acid, should not be rendered more than faintly opalescent (absence of *chloride*). On digesting a portion of the salt—which has been found to be free from chloride, or from which the latter has been completely removed by repeated digestion with ammonium carbonate—for five minutes with 10 C.c. of

* "Take of Nitrate of Silver, Ferrocyanide of Potassium, each, *two troyounces*; Sulphuric Acid *a troyounce and a half*; Distilled Water *a sufficient quantity*. Dissolve the Nitrate of Silver in a pint of Distilled Water, and pour the solution into a tubulated glass receiver. Dissolve the Ferrocyanide of Potassium in ten fluidounces of Distilled Water, and pour the solution into a tubulated retort, previously adapted to the receiver. Having mixed the Sulphuric Acid with four fluidounces of Distilled Water, add the mixture to the solution in the retort, and distil, by means of a sand-bath, with a moderate heat, until six fluidounces have passed over, or until the distillate no longer produces a precipitate in the receiver. Lastly, wash the precipitate with Distilled Water, and dry it." *U. S.* 1870.

ammonia water, and supersaturating the filtrate with nitric acid, only a slight opalescence, but no yellowish-white precipitate, should be produced (absence of *bromide*)." *U. S.*

Medical Properties. Dr. Chas. Patterson, of Dublin, states that this salt possesses the general medical properties of silver nitrate, and may be used without any danger of producing discoloration of the skin, but in the latter assertion he is probably incorrect. The dose is one or two grains (0·065–0·13 Gm.), three times a day, given in the form of pill.

ARGENTI NITRAS. U. S., Br. Silver Nitrate.

$AgNO_3$; 169·55. (ĂR-JĔN'TĪ NĪ'TRĂS.) **$AgNO_3$; 169·7.**

"A salt, $AgNO_3$, prepared by the interaction of nitric acid and silver." *Br.*

Nitrate of Silver, Lunar Caustic; Argentum Nitricum Crystallisatum, *P. G.;* Azotas (Nitras) Argenticus; Azotate d'Argent, Nitre lunaire, *Fr.;* Salpetersaures Silberoxyd, Silbersalpeter, *G.*

The U. S. and Br. Pharmacopœias do not give processes for making this salt. The U. S. Pharmacopœia, 1870, gave the following. "Take of Silver, in small pieces, *two troyounces;* Nitric Acid *two troyounces and a half;* Distilled Water *a sufficient quantity.* Mix the Acid with a fluidounce of Distilled Water in a porcelain capsule, add the Silver to the mixture, cover it with an inverted glass funnel, resting within the edge of the capsule, and apply a gentle heat until the metal is dissolved, and red vapors cease to be produced; then remove the funnel, and, increasing the heat, evaporate the solution to dryness. Melt the dry mass, and continue the heat, stirring constantly with a glass rod, until free nitric acid is entirely dissipated. Dissolve the melted salt, when cold, in six fluidounces of Distilled Water, allow the insoluble matter to subside, and decant the clear solution. Mix the residue with a fluidounce of Distilled Water, filter through paper, and, having added the filtrate to the decanted solution, evaporate the liquid until a pellicle begins to form, and set it aside in a warm place to crystallize. Lastly, drain the crystals in a glass funnel until dry, and preserve them in a well-stopped bottle. By evaporating the mother-water, more crystals may be obtained."

In the above process two peculiarities deserve notice. One of these is the direction to cover the materials in the capsule, during the continuance of the reaction, with a glass funnel. This is in order to prevent the escape of fumes and to economize the nitric acid, a portion of which rises in vapor, and, being condensed on the inner surface of the funnel, falls again into the capsule. The second peculiarity is the fusion of the salt before being dissolved; the effect is to decompose any copper nitrate that might have been derived from the silver, which, if coin be employed, always contains copper. The heat decomposes the copper nitrate, and the comparatively insoluble oxide is formed, which remains on the filter when the mass is subsequently dissolved in water and filtered, the silver nitrate not being decomposed by the heat used.

A practical method for separating the copper nitrate used in Calcutta depends upon the fact that strong nitric acid only slightly dissolves silver nitrate in the presence of copper nitrate. The silver nitrate is crystallized out from the first solution as long as it can be obtained pure, and the bluish-green mother-liquor is evaporated to dryness; the powdered salt, placed in a funnel stopped with asbestos, is percolated with nitric acid (sp. gr. 1·42). This washes out all of the copper nitrate, and the silver nitrate can be freed from the adhering nitric acid by heat. (*P. J. Tr.*, 1897, 61.)

During the solution of silver in nitric acid, part of the acid is decomposed and nitric oxide is given off, which becomes red by contact with the atmosphere, and the oxygen oxidizes the silver. This is taken up by the remainder of the acid, and produces silver nitrate in solution, which, by due evaporation, furnishes crystals of the salt. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both hydrochloric and sulphuric acids, should never be used. The hydrochloric acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble silver sulphate.* For an account of the manufacture of silver nitrate on a large scale, see *Druggists' Circular*, 1887, p. 3.

* It is desirable that pure silver, free from copper, should be used in this process. As silver coin always contains copper, it should be purified before being employed. For this purpose, according to the method of M. Lienau, it should be dissolved in nitric acid, and the solution precipitated by chlorine water, which throws down the silver only in the form of chloride. The precipitate is to be well washed with chlorine water, then dissolved in solution of ammonia, and precipitated by clean copper wire. The silver is deposited as a black powder, which, when washed with solution of ammonia, is perfectly pure. (See *A. J. P.*, 1862, p. 368.)

Properties. Silver nitrate is in "colorless, transparent, tabular, rhombic crystals, becoming gray or grayish-black on exposure to light in presence of organic matter, odorless, having a bitter, caustic, and strongly metallic taste and a neutral reaction. Soluble, at 15° C. (59° F.), in 0·6 part of water, and in 26 parts of alcohol; in 0·1 part of boiling water, and in 5 parts of boiling alcohol. When heated to about 200° C. (392° F.), the salt melts, forming a faintly yellow liquid, which, on cooling, congeals to a pure white, crystalline mass. At a higher temperature it is gradually decomposed with evolution of nitrous vapors." *U. S.* "Soluble in ether and glycerin." *Br.* The solution stains the skin an indelible black color, and is itself discolored by the most minute portion of organic matter, for which it forms a delicate test. The affinity of this salt for animal matter is evinced by its forming definite compounds with albumen and fibrin. The solution also stains linen and muslin in a similar manner; and hence its use in making the so-called indelible ink. To remove these stains, Mr. W. B. Herapath advises to let fall on the moistened spots a few drops of tincture of iodine, which converts the silver into silver iodide. The iodide is then dissolved by a solution of sodium hyposulphite, made with from half a drachm to a fluidounce of water, or by a moderately dilute solution of caustic potassa, and the spots are washed out with warm water. Silver stains may also be taken out by a solution of two and a half drachms of potassium cyanide, and fifteen grains of iodine, in three fluidounces of water. Dr. H. Kraetzer recommends, instead of potassium cyanide, a solution of 10 parts sal ammoniac and 10 parts corrosive sublimate in 100 parts of water, with which the stains are said to be removed readily from the hands, and from linen, wool, and cotton without injuring the fabric. (*Archiv d. Pharm.*, 1880, 52.) Silver nitrate is incompatible with most spring and river waters, on account of a little common salt usually contained in them; with soluble chlorides; with hydrogen sulphide, sulphuric, hydrochloric, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime water; and with astringent infusions. It is sometimes improperly prescribed in pill with tannic acid, by which it is decomposed. Silver nitrate is an anhydrous salt, consisting of one atom of silver, combined with the monatomic group characteristic of nitric acid.

Impurities and Tests. Hydrochloric acid or a solution of sodium chloride, added in excess to one of silver nitrate, should throw down the whole of the silver as a white curdy precipitate darkening on exposure to light, and nothing besides. This precipitate should be entirely soluble in ammonia. If not so, the insoluble part is probably lead chloride. If the supernatant liquid, after the removal of the precipitate, be discolored or precipitated by hydrogen sulphide, the fact shows the presence of metallic matter, which is probably copper or some remains of lead, or both. The solution, after precipitation by hydrochloric acid and filtration, should leave no residue when evaporated. A piece of the salt, heated on charcoal by the blow-pipe, melts, deflagrates, and leaves behind a whitish metallic coating. After all, the best sign of the purity of silver nitrate is the characteristic appearance of the crystals. "An aqueous solution of the salt is neutral to litmus paper, and yields, with hydrochloric acid, a white precipitate, which is readily dissolved, without color (absence of *copper*), by ammonia water. If 5 C.c. of a 10-per-cent. aqueous solution of the salt be mixed with 20 C.c. of diluted sulphuric acid, and heated to boiling, no turbidity should be perceptible (absence of *lead*). If another portion of the aqueous solution be completely precipitated by hydrochloric acid, and the filtrate evaporated to dryness, no residue should be left (absence of *foreign salts*). 0·34 (0·3391) Gm. of Silver Nitrate, dissolved in 10 C.c. of water, should require, for complete precipitation, 20 C.c. of sodium chloride decinormal volumetric solution (corresponding to 100 per cent. of the pure salt)." *U. S.* "1 gramme dissolved in 15 cubic centimetres of *water* affords with *hydrochloric acid* a precipitate, which, when thoroughly washed and dried, should weigh 0·843 gramme. The filtrate, when evaporated to dryness on a water-bath, should leave no residue." *Br.*

Medical Properties and Uses. When silver nitrate in a pure state is brought in contact with a living tissue, it acts as an escharotic. Owing to the formation of a dense film of coagulated albumen, the depth of its action is very limited; the albuminous coating is at first white, but soon becomes blackish, owing to the reduction of the silver. The solution of the salt is, if not too strong, a local stimulant and astringent, and is very largely employed (grs. xx to f℥i) in ordinary *angina*, or more concentrated (grs. xxx to f℥i) in *diphtheria*, and is also used in *inflammations of the urethral and conjunctival mucous membranes;* for the latter purpose the strength should usually not exceed one or two grains to the ounce. As a counter-irritant, stimulant, and alterative, or an escharotic in various *external ulcerations*, morbid growths, etc., silver nitrate finds a very wide use. It is largely employed, also, internally in

inflammations and *ulcerations* of the *alimentary tract*, such as *subacute gastritis*, *pyrosis*, *ulcer of the stomach*, *chronic diarrhœa*, *catarrh of the gall-ducts*, etc. In all stomachic diseases it should be given half an hour before eating, so as to reach as thoroughly as possible the gastric mucous membrane. Dr. Boudin, of Marseilles, employed it in *typhoid fever*, and Prof. Wm. Pepper has followed the practice with asserted brilliant results. As it has been found in all the tissues of the body, it is undoubtedly absorbed. It is soluble in peptones, and is probably so taken up, although some believe that it is converted in the stomach into a soluble double chloride with sodium or potassium. It is never used in practical medicine to produce an acute impression on the general system, but was at one time much employed as a slowly acting alterative in certain nervous affections, especially *epilepsy* and *chronic spinal inflammation*, such as *locomotor ataxia*, *spasmodic tabes*, *tabes dorsalis*, etc., but this method of treatment has about passed out of vogue. The occasional production of a slate-colored discoloration of the skin is a great drawback to the long-continued use of the nitrate, but it probably never occurs under a course of the remedy of less than two months. It affects also the mucous membrane, and, according to Dr. Branson (confirmed by Dr. Wm. Pepper), an indication of the approach of discoloration is furnished by the occurrence of a dark-blue line on the edges of the gums, very similar to that produced by lead, but somewhat darker. When once produced, the discoloration seems to be permanent, although Dr. L. P. Yandell has reported two cases in which the discoloration of the skin disappeared during a course of potassium iodide. (*N. R.*, July, 1873.)

The dose of silver nitrate (crystals) is the fourth of a grain (0·016 Gm.), gradually increased to half a grain (0·03 Gm.), three times a day. For internal exhibition, the physician should always prescribe the crystals, and never direct the fused nitrate, which may not be pure. Silver nitrate should always be given in pill, as the solution is decomposed by the liquids of the mouth. It should not be made up into pill with crumb of bread, as this contains common salt, but with some vegetable powder and mucilage, preferably powdered sugar of milk with an excipient of glucose. But, as all organic substances decompose it more or less, M. Vée proposes the use of inorganic matter, such as nitre, or preferably pure silica obtained by precipitating one of the silicates by an acid, and washing it. The least possible proportion of tragacanth may be used to give adhesiveness to the mass. (*Journ. de Pharm.*, Mai, 1864, p. 408.)

When ingested in sufficient dose, silver nitrate is a violent poison, and has several times caused death. The symptoms are those of toxic gastro-enteritis, with marked constitutional disturbance, especially coma, convulsions, paralysis, and profound alteration of the respiration. The treatment of the poisoning resolves itself into the use of the ordinary antidotes (common salt, soap, alkalies, etc.).

ARGENTI NITRAS DILUTUS. U. S. (Br.) Diluted Silver Nitrate.

[Mitigated Caustic.]

(ĂR-JĔN'TĪ NĪ'TRĂS DĮ-LŪ'TŬS.)

Argenti Nitras Mitigatus, *Br.*, Mitigated Caustic; Silver and Potassium Nitrate.

"Silver Nitrate, *thirty grammes* [or 463 grains]; Potassium Nitrate, *sixty grammes* [or 2 ounces av., 51 grains]. Melt the salts together in a porcelain crucible, at as low a temperature as possible, stirring the melted mass well until it flows smoothly. Then cast it into suitable moulds. Keep the product in dark amber-colored vials." *U. S.*

"Silver Nitrate, 1 *ounce* (Imperial) or 20 grammes; Potassium Nitrate, 2 *ounces* (Imp.) or 40 grammes. Fuse and mix thoroughly in a capsule of platinum or thin porcelain, and pour the melted mass into proper moulds." *Br.*

The introduction of these preparations grew out of the frequent demand for a fused silver nitrate which would not be so severe in its action as the pure article. The manufacturers have been furnishing for many years a "*No. 2 Lunar Caustic*," which contains 67 per cent. of pure silver nitrate; the diluted nitrate of the U. S. P. 1880 contained 50 per cent. of lunar caustic, but the present Pharmacopœia has further reduced the strength to 33 per cent., and it is now identical with the British preparation.

Properties. Diluted silver nitrate is officially described as "a white, hard solid, generally in the form of pencils or cones of a finely granular fracture, becoming gray or grayish-black on exposure to light in presence of organic matter; odorless, having a caustic, metallic taste, and neutral to litmus paper. Each of its constituents retains the solubility in water and in alcohol mentioned, respectively, under *Argenti Nitras* and *Potassii Nitras*. An aqueous solution of Diluted Silver Nitrate yields, with a slight excess of hydrochloric acid, a white pre-

cipitate, which is readily soluble in ammonia water. The filtrate from this precipitate, when evaporated to dryness, yields a white residue which is completely soluble in water, and this solution affords a yellow, crystalline precipitate with platinic chloride test-solution, and a white, crystalline precipitate with sodium bitartrate test-solution. If to an aqueous solution of Diluted Silver Nitrate a slight excess of ammonia water be added, it should neither assume a blue color (absence of *copper*), nor show any turbidity (absence of *lead* and *bismuth*). If 1 Gm. of Diluted Silver Nitrate, dissolved in 10 C.c. of water, be mixed with 20 C.c. of sodium chloride decinormal volumetric solution and a few drops of potassium chromate test-solution, not more than 0·5 C.c. of silver nitrate decinormal volumetric solution should be required to impart to the liquid a permanent red color (corresponding to at least 33 per cent. of pure silver nitrate)." *U. S.* "White or grayish-white cylindrical rods or cones; freely soluble in *water*, but only sparingly so in *alcohol* (90 per cent.). 3 grammes dissolved in 15 cubic centimetres of *water* should afford with *hydrochloric acid* a precipitate, which, after washing with hot *water* and drying, weighs 0·843 gramme." *Br.*

Medical Properties. This preparation is used only externally. It is similar in its action to the fused nitrate, but less energetic.

ARGENTI NITRAS FUSUS. U. S. (Br.) Moulded Silver Nitrate. [Lunar Caustic.]

(ĂR-ĢĔN'TĪ NĪ'TRĂS FŪ'SŬS.)

Argenti Nitras Induratus, *Br.*, Toughened Caustic; Lunar Caustic; Lapis Infernalis, Argentum Nitricum Fusum, *P.G.;* Azotas (Nitras) Argenticus Fusus; Azotate d'Argent fondu, Pierre infernale, *Fr.;* Höllenstein, Geschmolzenes Salpetersaures Silberoxyd, *G.;* Fused Nitrate of Silver.

"Silver Nitrate, *one hundred grammes* [or 3 ounces av., 231 grains]; Hydrochloric Acid, *four grammes* [or 62 grains]. To the Silver Nitrate, contained in a porcelain capsule, add the Hydrochloric Acid, and melt the mixture at as low a temperature as possible. Stir well, and pour the melted mass into suitable moulds. Keep the product in dark amber-colored vials, protected from light." *U. S.*

"Silver Nitrate, 475 *grains* (Imperial) or 95 grammes; Potassium Nitrate, 25 *grains* (Imp.) or 5 grammes. Fuse and mix thoroughly in a capsule of platinum or thin porcelain, and pour the melted mass into proper moulds." *Br.*

For most purposes it is desirable to have the silver nitrate less brittle than in its pure state. Prof. J. L. Smith, of Louisville, Ky., found that this could be effected by adding a little silver chloride, which rendered the stick tough, without materially impairing its efficiency. Dr. Squibb proposed to accomplish the object by adding 40 grains of hydrochloric acid, with half a fluidounce of distilled water, to two ounces of silver nitrate, heating the mixture by means of a sand-bath to dryness, and then melting and casting into moulds. (*Proc. A. P. A.*, 1858.) This process has been practically adopted in the U. S. Pharmacopœia. In order to keep the sticks from becoming discolored during the casting process, it is advisable to add a diluted nitric acid (1 in 5) occasionally to the melted nitrate, and carefully prevent the mass from becoming overheated. In the British process the "toughening" is effected by the addition of 5 per cent. of potassium nitrate. In our opinion, this is not as efficient as is the use of hydrochloric acid. As the salt while melting penetrates a common crucible, the fusion is performed in one of porcelain or platinum, the size of which should be sufficient to hold five or six times the quantity of the salt operated on, in order to prevent its boiling over. Sometimes small portions of the liquid are spurted out, and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should be warmed, but not greased, as the organic matter would partially decompose the fused salt.

Properties. Moulded silver nitrate, as prepared by the above process, is in the form of hard brittle sticks of the size of a goose-quill, at first translucent, but quickly becoming gray or more or less dark under the influence of light, owing to the reduction of the silver, effected probably by organic matter or hydrogen sulphide contained in the atmosphere. That the change does not depend on the sole action of light has been proved by Mr. Scanlan, who finds that silver nitrate in a clean glass tube hermetically sealed undergoes no change by exposure to light. The sticks often become dark-colored and nearly black on the surface, and when broken across, exhibit a crystalline fracture with a radiated surface. Moulded silver nitrate, when pure, is wholly soluble in distilled water; but even fair samples of the moulded salt will not totally dissolve, a very scanty black powder being left of reduced silver, arising probably from the salt

having been exposed to too high a heat in fusion. Stein (*Schweiz. Wochenschrift für Pharmacie*, 6, 10, 1877) recommends a plan for obtaining sticks of lunar caustic of special diameter or length by taking a glass tube or rod of the required outside diameter and wrapping around it moistened parchment paper, pasting the edges, tying the lower end, and drying. The melted lunar caustic is poured into the paper mould, held upright in a test-tube, and allowed to cool by standing. *Elastic crayons* of silver nitrate may be made by taking a laminaria tent $\frac{1}{10}$ of an inch (0·002 mm.) in diameter, dipping it into thick mucilage, rolling it in finely-powdered lunar caustic, and drying it. (*Pajot.*) Entirely black lunar caustic is sometimes seen in France, which contains about 2 per cent. of potassium nitrate and the same quantity of black manganese oxide. Heller's caustic pencils look like ordinary lead-pencils, and consist of long, thin sticks of lunar caustic, encased in wood; they may be sharpened like lead-pencils, and the point protected by a cap to prevent injury when not in use. "A white, hard solid, generally in the form of pencils or cones of a fibrous fracture, becoming gray or grayish-black on exposure to light in the presence of organic matter, odorless, and having a bitter, caustic, and strongly metallic taste. Soluble at 15° C. (59° F.), with the exception of about 5 per cent. of silver chloride, in 0·6 part of water, and in 26 parts of alcohol; in 0·1 part of boiling water, and in 5 parts of boiling alcohol. The portion left undissolved by water should be completely soluble in ammonia water." *U. S.*

Impurities and Tests. Moulded silver nitrate is liable to contain free silver from having been exposed to too high a heat, lead and copper nitrates from the impurity of the silver dissolved in the acid, and potassium nitrate from fraudulent admixture or otherwise. Free silver will be left undissolved as a black powder, after the action of distilled water. A very slight residue of this kind is hardly avoidable; but if there be much free silver it will be shown by the surface of a fresh fracture of one of the sticks presenting an unusually dark gray color. (*Christison.*) The mode of detecting lead and copper is explained under silver nitrate. (See *Argenti Nitras.*) "A clear, aqueous solution of the salt, decanted from the insoluble portion, should be neutral to litmus paper, and should respond to the tests of identity and purity mentioned under *Argenti Nitras.* If 0·34 Gm. of Moulded Silver Nitrate, dissolved as completely as possible in 10 C.c. of water, be mixed with 20 C.c. of sodium chloride decinormal volumetric solution and a few drops of potassium chromate test-solution, not more than 1 C.c. of silver nitrate decinormal volumetric solution should be required to impart to the liquid a permanent red color (corresponding to 95 per cent. of pure silver nitrate)." *U. S.* In order to detect potassium nitrate, a solution of the suspected salt should be treated with hydrochloric acid in excess, to remove silver, and with hydrogen sulphide, to throw down other metals if they happen to be present. The filtered liquid, if the salt be pure, will entirely evaporate by heat; if it contain potassium nitrate, this will be left, easily known by its properties as a nitrate. This impurity sometimes exists in moulded silver nitrate in large amount, varying, according to different statements, from 10 to 75 per cent. According to Dr. Christison, it may be suspected if the sticks present a colorless fracture. Prof. Pollacci (*Journ. de Pharm.*, 4e sér., xvii. 160) states that if silver nitrate, after having been heated in a porcelain capsule to redness and cooled, imparts an alkaline reaction to water, it contains nitre. In the Br. Pharmacopœia the following method is given for testing toughened silver nitrate for impurity; the British preparation contains no hydrochloric acid. "1 gramme, dissolved in 15 cubic centimetres of *water*, should yield with *hydrochloric acid* a precipitate, which, when washed and dried, should weigh 0·8 gramme, and the filtrate when evaporated should leave a white residue." If the weight of the precipitate be greater or less than here stated, there must be some impurity in the nitrate; and any non-precipitable matter, if solid at the temperature of the water-bath, will be left behind when the filtrate is evaporated.

Medical Properties. Moulded silver nitrate should be restricted to external use. Externally applied, the moulded nitrate acts variously as a stimulant, vesicant, and escharotic, and may be employed either dissolved in water or in the solid state. A drachm of the moulded salt, dissolved in a fluidounce of water, forms an escharotic solution, which may often be resorted to with advantage. But moulded silver nitrate is most frequently employed in the solid state; and, as it is not deliquescent nor apt to spread, it forms the most manageable caustic that can be used. If the moulded nitrate be rubbed gently over the moistened skin until this becomes gray, it generally vesicates, causing usually less pain than is produced by cantharides. The fused nitrate is also employed to destroy *strictures of the urethra*, *warts* and *excrescences*, *fungous flesh*, *incipient chancres*, and the *surface of other ulcers.*

It is often of service lightly applied, either in concentrated solution or in stick, to ulcers in

expediting their cicatrization. It is very largely employed in the local treatment of *inflammations of the mucous membranes*, as in *cystitis*, *leucorrhœa*, *gonorrhœa*, *conjunctivitis*, *faucitis*, *laryngitis*, etc. In these cases the strength of the solution must be adapted to the susceptibility and the exact condition of the membrane. In cases of intense and especially of specific inflammations, the solution may be a saturated one, the object being to destroy the specific granulations: thus, in *gonorrhœal conjunctivitis*, and in virulent *diphtheritic faucitis*, even the solid stick is used by some practitioners, whereas in ordinary conjunctivitis the strength should rarely be above one or two grains to the ounce, and in faucitis twenty to forty grains to the ounce. Strong solutions of silver nitrate are sometimes used for the *aborting of a gonorrhœa*, but the treatment is usually considered dangerous, as liable to increase the intensity of the inflammation if unsuccessful. In the advanced stages of gonorrhœa a solution of three to five grains to the ounce may be injected.

Lunar caustic is also frequently used as a topical remedy in various superficial inflammations. The method originated in 1820 by Mr. John Higginbottom of treating *erysipelas* by silver nitrate still finds favor with some of the profession. After thorough washing of the skin with soap and water, and afterwards with pure water, and subsequent drying, a concentrated solution of twenty grains of silver nitrate to a drachm of distilled water is applied freely on the inflamed surface and beyond it on the healthy skin by means of a linen mop. In various inflammations of the subcellular tissues silver nitrate often acts advantageously: thus, applied to the skin in sufficient concentration to blacken the surface, it will sometimes avert a *felon* or an *epididymitis*. It has been employed by injection for the radical cure of *hydrocele*, and in solid stick applied as a fine point to each *pustule of small-pox* upon the face for the prevention of pitting.

ARGENTI OXIDUM. U. S., Br. Silver Oxide.

Ag_2O; 231·28. (ĂR-ĢĔN′TĪ ŎX′Ĭ-DŬM.) Ag_2O; 231·4.

"Silver Oxide should be kept in dark amber-colored vials. It should not be triturated with readily oxidizable or combustible substances, and should not be brought in contact with ammonia." *U. S.* "Silver Oxide, Ag_2O, is prepared by mixing solutions of silver nitrate and calcium hydroxide." *Br.*

Argentum Oxydatum, Argentic Oxide; Oxyde d'Argent, *Fr.*; Silberoxyd, *G.*

A process for preparing silver oxide has not been adopted in either of the present U. S. or Br. Pharmacopœias; that of the U. S. Pharmacopœia of 1870 is given below.*

Silver oxide was introduced into the U. S. Pharmacopœia of 1850, and was adopted in the Br. Pharmacopœia from the Dublin. In the processes for making it, silver nitrate is decomposed by potassa or lime, the oxide being precipitated, and potassium nitrate or calcium nitrate, as the case may be, remaining in solution. When thus obtained, the oxide is an olive-brown powder. If the potassa used be not wholly free from carbonic acid, the precipitated oxide will be contaminated with some silver carbonate. According to Mr. Borland, of London, the carbonate is sometimes sold for the oxide. A third process for obtaining this oxide is that of Gregory, which consists in boiling the moist, recently-prepared silver chloride with a very strong solution of caustic potassa (sp. gr. 1·25 to 1·30), when, by double decomposition, silver oxide and potassium chloride are formed.

Properties and Tests. "A heavy, dark brownish-black powder, liable to reduction by exposure to light, odorless, and having a metallic taste. Very slightly soluble in water, to which it imparts an alkaline reaction, and insoluble in alcohol, but readily and completely soluble in nitric acid without effervescence (absence of *carbonate*). When heated to about 250° to 300° C. (482° to 572° F.), it is rapidly decomposed, with the evolution of oxygen, and leaving a residue of metallic silver. The solution of the oxide in nitric acid should be colorless, and should respond to the reactions and tests mentioned under Silver Nitrate (see *Argenti Nitras*). If 0·5 Gm. of the Oxide be ignited in a porcelain crucible, it should yield 0·465 Gm. (or 93·1 per cent.) of metallic silver." *U. S.* "A brown powder, which at a low red heat gives off oxygen and yields metallic silver. It dissolves in *nitric acid* without the evolution of any reddish fumes (absence of metallic silver). Each gramme, dissolved in *nitric acid*, should yield with *hydrochloric acid* a precipitate, which, when thoroughly washed and dried, weighs

* "Take of Nitrate of Silver *four troyounces;* Distilled Water *half a pint;* Solution of Potassa *a pint and a half*, or *a sufficient quantity*. Dissolve the Nitrate of Silver in the Water, and to the solution add Solution of Potassa so long as it produces a precipitate. Wash this repeatedly with water until the washings are nearly tasteless. Lastly, dry the precipitate and keep it in a well-stopped bottle, protected from the light." *U.S.* 1870.

1·237 grammes. It should yield no characteristic reaction with the tests for lead, copper, or iron. Silver Oxide is liable to decompose with violence when mixed with creosote, phenol, potassium permanganate, and many other substances." *Br.* When its solution in nitric acid is precipitated by sodium chloride in excess, the supernatant liquid is not discolored by ammonium sulphide. The non-action of this test shows the absence of most foreign metals, especially copper and lead. It parts with its oxygen with great facility, being decomposed by many organic substances; in this way it causes sulphur, amorphous phosphorus, or tannin to take fire when rubbed together with it quite dry, in a mortar.

Medical Properties and Uses. This oxide has been proposed as a substitute for silver nitrate, as having the general therapeutic virtues of the latter, without its escharotic effect and its objectionable property of discoloring the skin. Experience, however, has shown that it will tint the skin. (*New York Med. Journ.*, June, 1869; *Phila. Med. Times*, vi.) It was first tried as a medicine by Van Mons and Sementini. In 1840 it was employed by Dr. Butler Lane, who considered it to act as a sedative. In 1845 the late Sir James Eyre strongly recommended it in his work on exhausting diseases. Dr. Lane used it with more or less success in *nausea*, *cardialgia*, *pyrosis*, various *painful affections of the stomach* without organic lesion, *dysentery*, *diarrhœa*, *night-sweats* without other obvious affection, *dysmenorrhœa*, *menorrhagia*, *leucorrhœa*, *chronic enlargements of the uterus* attended with flooding, etc. The oxide appeared to exert a peculiar control over *uterine fluxes*. Some of the cases treated required the use of tonics after the curative influence of the oxide had been exerted. The late Dr. Golding Bird also obtained favorable effects from the use of silver oxide, and confirmed to a certain extent the results of Dr. Lane, especially as to its valuable powers in *menorrhagia*. In stomach disease characterized by a glairy instead of a watery discharge, Dr. Bird derived not the slightest benefit from the oxide, though he used it in thirty cases. In *tænia* it has been used successfully in two cases by Mr. Whittel. The dose of silver oxide is a grain (0·065 Gm.) twice or thrice a day. If pills are ordered, they should not be made with honey, conserve of roses, or other excipient containing glucose; and, indeed, most organic substances, especially in a moist state, deoxidize the oxide, reviving the silver. There would seem to be need of great caution in making these pills. Dr. Jackson has recorded a case in which pills of silver oxide, morphine muriate, and extract of gentian exploded violently in the pocket of the patient. (*P. J. Tr.*, xi. 552.) Pills may be made with gum arabic, but it is better to dispense the dry powder in capsules. An ointment, from five to ten grains to the drachm, has been used as an application to *venereal sores*, and to the urethral membrane in *gonorrhœa*, smeared on a bougie.

ARMORACIÆ RADIX. Br. Horse-radish Root.

(ÄR-MO-RĀ'CI-Æ RĀ'DIX.)

"The fresh root of Cochlearia Armoracia, Linn., collected from cultivated plants." *Br.*

Armoracia, Br. 1864; Raifort sauvage, Moutarde des Moines, Radis de Cheval, *Fr.;* Meerrettig, *G.;* Rafano rusticano, *It.;* Rabano rusticano, *Sp.*

Gen. Ch. Silicula emarginate, turgid, scabrous with gibbous, obtuse valves. *Willd.*

Cochlearia Armoracia. Willd. *Sp. Plant.* ii. 451; Woodv. *Med. Bot.* p. 400, t. 145. The root of this plant is perennial, sending up numerous very large leaves from the midst of which a round, smooth, erect, branching stem rises two or three feet in height. The radical leaves are lance-shaped, waved, scolloped on the edges, sometimes pinnatifid, and stand upon strong footstalks. Those of the stem are much smaller, without footstalks, sometimes divided at the edges, sometimes almost entire. The flowers are numerous, white, peduncled, and form thick terminal clusters. The calyx has four ovate, deciduous leaves, and the corolla an equal number of obovate petals, twice as long as the calyx, and inserted by narrow claws. The pod is small, elliptical, crowned with the persistent stigma, and divided into two cells, each containing from four to six seeds.

The horse-radish is a native of western Europe, growing wild on the sides of ditches, and in other moist situations. It is cultivated for culinary purposes in most civilized countries, and is naturalized in some parts of the United States. Its flowers appear in June.

The root, which is official in its fresh state, is long, conical at top, then nearly cylindrical for some inches, at last tapering, whitish externally, very white within, fleshy, of a strong pungent odor when scraped or bruised, and of a hot, biting, somewhat sweetish, and sometimes bitterish taste. Its virtues are imparted to water and alcohol. They depend upon a *volatile oil*, which is dissipated by drying; the root becoming at first sweetish, and ultimately insipid and

quite inert. Its acrimony is also destroyed by boiling. The oil may be obtained by distillation with water. It is colorless or pale yellow, heavier than water, very volatile, excessively pungent, acrid, and corrosive, exciting inflammation and even vesication when applied to the skin. Hubatka considers it as identical with the volatile oil of mustard. He combined it with ammonia and obtained crystals of *thiosinamin*, $NH_2.CS.N(C_3H_5)H$, which agreed with that produced from mustard oil. (*Journ. de Pharm.*, 3e sér., v. 42.) According to Gutret, only six parts of it are obtained from 10,000 of the root. Besides this principle, the fresh root contains, according to the same chemist, a bitter resin in minute quantity, sugar, extractive, gum, starch, albumen, acetic acid, calcium sulphate and acetate, water, and lignin. A. Hilger found in the ashes of the root of horse-radish, lime, magnesia, potassa, a trace of soda and iron oxide, with sulphuric, hydrochloric, carbonic, phosphoric, and silicic acids in combination. (*Chem. Centralbl.*, p. 597, 1878; *A. J. P.*, 1879, p. 21.) From observations made by F. L. Winckler, it may be inferred that *myronic acid* exists in the root combined with potassa, and that it is from the reaction between this acid, *myrosine*, also existing in the root, and water, that the volatile oil is produced, in the same manner as oil of mustard from mustard seed. (See *Sinapis*.) Horse-radish when distilled with alcohol yields none of the oil. (*Journ. für Prakt. Pharm.*, xviii. 89.) The root may be kept for some time without material injury, if buried in sand in a cool place.

It is said that if to the powder of the dried root, which has become apparently inert, the emulsion of white mustard seed containing myrosine be added, it reacquires its original irritant properties; so that it is the myrosine and not the potassium myronate which is injured by drying. Hence the powdered root may be added with advantage to mustard in preparing cataplasms, pediluvia, etc. (*Journ. de Pharm. et de Chim.*, xxvii. 268.)*

Medical Properties and Uses. Horse-radish is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally it is rubefacient. Its chief use is as a condiment to promote appetite and invigorate digestion; but it is also occasionally employed as a medicine, particularly in *dropsy* attended with enfeebled digestion and general debility. It has, moreover, been recommended in *palsy* and *chronic rheumatism*, both as an internal and an external remedy, and in *scorbutic affections* is highly esteemed. Cullen found advantage in cases of *hoarseness*, from the use of a syrup prepared from an infusion of horse-radish and sugar, and slowly swallowed in the quantity of one or two teaspoonfuls, repeated occasionally. The root may be given in the dose of half a drachm (1·95 Gm.) or more, grated or cut into small pieces.

ARNICÆ FLORES. U. S. Arnica Flowers.

(ĂR'NĮ-ÇÆ FLŌ'RĒŞ.)

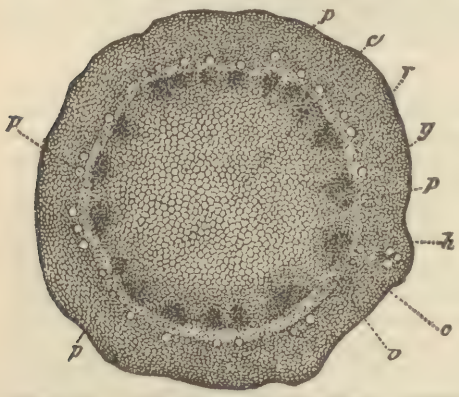
Arnica montana. Willd. *Sp. Plant.* iii. 2106; *B. & T.* 158. This is a perennial, herbaceous plant, having a woody, brownish, horizontal root, from one to three inches long, and two or three lines thick, ending abruptly, and sending forth numerous slender fibres of the same color. The stem is about a foot high, cylindrical, striated, hairy, and terminating in one, two,



* The French Codex contains a formula for a *Compound Syrup of Horse-radish* (*Sirop Antiscorbutique*), as follows. Scurvy-grass, water-cress, horse-radish (root), all fresh, of each, 100 parts, buckbean (marsh trefoil), fresh, 10 parts, bitter orange peel 20 parts, canella 5 parts, white wine 400 parts, sugar 500 parts. Thoroughly contuse and comminute the solid ingredients, macerate for 48 hours with the wine, and distil off 100 parts. Express and strain the residue from the distillation, clarify the liquid with white of egg, and strain; add 300 parts sugar, and make into a syrup of sp. gr. 1·270 whilst boiling; with the rest of the sugar and sufficient water make a thick syrup, mix this with the other syrup, allow to cool, then add the distilled essence. *Iodized Syrup of Horse-radish* may be made by adding one part of tincture of iodine to ninety-nine parts of the compound syrup above.

or three peduncles, each bearing a flower. The radical leaves are ovate, entire, ciliated, and obtuse; those of the stem, which usually consist of two opposite pairs, are lance-shaped. Both are bright green, and somewhat pubescent on their upper surface. The flowers are yellow.

This plant is a native of the mountainous districts of Europe and Siberia, and is found, according to Nuttall, in the northern regions of this continent, west of the Mississippi. It has been introduced into England, and might no doubt be cultivated in this country. The flowers, leaves, and root are employed; but the flowers are usually preferred.

Properties. The whole plant, when fresh, has a strong, disagreeable odor, which is apt to excite sneezing, and is diminished by drying. The taste is acrid, bitterish, and durable. The dried root is cylindrical, contorted, and marked by scars from the insertion of the leaves. Water extracts its virtues. The Pharmacopœia thus describes the flowers and the root:

"Heads about 3 Cm. [one and one-fifth inch] broad, depressed-roundish, consisting of a scaly involucre in two rows, and a small, nearly flat, hairy receptacle, bearing about sixteen yellow, strap-shaped, ten-nerved ray-florets, and numerous yellow, five-toothed, tubular disk-florets, having slender, spindle-shaped achenes, crowned by a hairy pappus. Odor feeble, aromatic; taste bitter and acrid." *U. S.*

Arnica root. *c*, pith, marrow; *h*, outer bark; *o*, middle bark; *p*, resin-tubes; *y*, woody bundles.

"Rhizome about 5 Cm. [two inches] long, and 3 or 4 Mm. [one-eighth to one-sixth inch] thick; externally brown, rough from leaf-scars; internally whitish, with a rather thick bark, containing a circle of resin-cells, surrounding the short, yellowish wood-wedges, and large, spongy pith. The roots numerous, thin, fragile, grayish-brown, with a thick bark containing a circle of resin-cells. Odor somewhat aromatic; taste pungently aromatic and bitter." *U. S.*

Bastick (*P. J. Tr.*, x. 389) separated an alkaloid from the flowers, to which he gave the name of *arnicine*. The *arnicine* of Walz (*N. Jahrb. Pharm.*, xiii.), extracted from both the root and the flowers, is a different substance; it is an amorphous yellow mass of acrid taste, slightly soluble in water, freely in alcohol or ether, and dissolving also in alkaline solutions. It is precipitable from its alcoholic solution by tannic acid or by water. Walz assigns to arnicine the formula $C_{20}H_{30}O_4$; other chemists that of $C_{35}H_{54}O_7$. Arnicine has not been proved to be a glucoside, although it is decomposed by dilute acids. Sigel (1873) obtained from dried arnica root about ½ per cent. of essential oil, and 1 per cent. from the fresh; the oil of the latter had a sp. gr. of 0·999 at 18° C. (64·4° F.). The oil was found to be a mixture of various bodies, the principal being the *dimethyl ether of thymohydroquinone*, $C_{10}H_{12}\left\{\begin{matrix}OCH_3\\OCH_3,\end{matrix}\right.$ boiling at about 235° C. (455° F.), and with this, *phloryl isobutyrate* to the extent of one-fifth of the oil, and the *methyl ether* of a *phlorol*. (*Pflanzenstoffe*, 2d ed., p. 1530.) The water from which the oil separates contains *isobutyric acid;* probably also a little *angelic* and *formic acids;* but neither capronic nor caprylic acid, which had been pointed out by Walz. Arnica root contains *inulin*, which Dragendorff extracted from it to the extent of about 10 per cent. (*Pharmacographia*, 2d edition, p. 391.)

Medical Properties and Uses. When taken internally in sufficient dose, arnica acts as an irritant to the stomach and bowels, often producing an emetic and cathartic effect, and is said by Bergius to be diuretic, diaphoretic, and emmenagogue. It is capable of acting as a poison in overdoses, causing burning in the stomach, violent abdominal pains, intense headache, and great nervous disturbance, with, in some cases, marked reduction of the pulse-rate, and finally collapse. A case of tetanic spasm of one side, and ultimate death, under its use, is on record; but there is reason to doubt whether arnica was the real cause of the fatal issue. (*Ann. de Thérap.*, 1854, p. 46.) It is much used by the Germans, who prescribe the flowers and root with advantage in *amaurosis*, *paralysis*, and other *nervous affections*. It is said to prove useful in that disordered condition which succeeds *concussion* of the *brain* from falls, blows, etc., and from this circumstance has received the title of *panacea lapsorum*. It has also been recommended in *chronic catarrh of the old*, *intermittent fever* and its sequelæ, *dysentery*,

diarrhœa, *nephritis*, *gout*, *rheumatism*, *passive hemorrhages*, *dropsy*, *chlorosis*, *amenorrhœa*, and various other complaints, in most of which it seems to have been empirically prescribed; but the exact value of the remedy has not been determined. The powdered flowers and leaves are employed as a sternutatory; and the inhabitants of Savoy and the Vosges are said to substitute them for tobacco. They may be given in substance or infusion. The dose of the powder is from five to twenty grains (0·33–1·3 Gm.) frequently repeated. The infusion may be prepared by digesting an ounce of the flowers in a pint of water, of which from half a fluidounce to a fluidounce (15–30 C.c.) may be given every three hours. It should always be strained through linen, in order to separate the fine fibres, which might irritate the throat. A tincture prepared from the flowers is largely used in this country as a domestic remedy in *sprains*, *bruises*, etc. It is employed externally. A tincture of the root is now official: this would be preferable for internal use. (See *Tinctura Arnicæ Radicis.*)

ARSENI IODIDUM. U. S. (Br.) Arsenic Iodide.

AsI_3; 454·49. (ĂR'SĒ-NĪ Ī-ŌD'Ī-DŬM.) AsI_3; 454·7.

"Arsenious Iodide, AsI_3, may be obtained by the direct combination of iodine and arsenium." *Br.*

Arsenii Iodidum, *Br.;* Arsenici Iodidum, *U. S.* 1870; Iodide of Arsenic, Arsenious Iodide; Arsenicum jodatum, Arsenik Jodür, *G.;* Iodure d'Arsenic, *Fr.*

"Arsenic Iodide should be kept in glass-stoppered vials, in a cool place, protected from light." This iodide was introduced into the U. S. Pharmacopœia for the purpose of being used in preparing the solution of arsenic and mercury iodide. It is made by the direct combination of its constituents, with the aid of a gentle heat.

For U. S. process of 1870 see foot-note.* J. F. Babcock (*Proc. A. P. A.*, 1875, p. 693) proposes to make it by placing a troyounce of iodine in a suitable vessel with 10 or 12 fluidounces of water, and passing hydrogen sulphide through until the iodine color is entirely gone; then filtering, heating the filtrate until the odor of hydrogen sulphide has been dissipated; then adding a quarter of a troyounce of arsenous acid, heating until dissolved, filtering, and evaporating to dryness. $As_2O_3 + 6HI = 2AsI_3 + 3H_2O$. Nickle's process enables the operator to obtain the salt in a crystalline condition. Arsenic and iodine in equivalent proportions are heated together with carbon disulphide in a flask, to which an upright condenser is attached, until the iodine color disappears. The solution is then evaporated to the crystallizing point.

In the *Berichte d. Deutsch. Chem. Ges.*, 2643, 1881, may be found a process for obtaining this salt chemically pure, by making a hot solution of arsenous acid in hydrochloric acid, and mixing it with a concentrated solution of potassium iodide, whereupon the teriodide separates as a crystalline powder; this may be washed with hydrochloric acid, sp. gr. 1·120, until a portion of the washings on evaporation ceases to leave a residue of potassium chloride.

Properties, etc. Arsenic iodide is in "glossy, orange-red, crystalline masses, or shining, orange-red, crystalline scales, having an iodine-like odor and taste, and gradually losing iodine on exposure to air and light. Soluble, at 15° C. (59° F.), in 7 parts of water, and in about 30 parts of alcohol; also soluble in ether, and in carbon disulphide. The salt is gradually decomposed by boiling water, and by boiling alcohol. By heat it is completely volatilized; and if it be heated with diluted nitric acid, vapor of iodine will be evolved. The aqueous solution of the salt has a yellow color, is neutral to litmus paper, and, on standing, gradually decomposes into arsenous and hydriodic acids. On adding hydrogen sulphide test-solution to the solution acidulated with hydrochloric acid, a lemon-yellow precipitate is produced." *U. S.* It has a great tendency to decompose even at ordinary temperatures, iodine separating and volatilizing, oxygen being absorbed and arsenous acid formed. Arsenic iodide as found in commerce varies greatly in composition, being usually deficient in arsenic. (See *Ephemeris*, vol. ii. p. 772.) It has been used by Biett as an external application in corroding *tubercular skin diseases*. By the late Dr. A. T. Thomson it was given internally with alleged advantage in *lepra*. The ointment used by Biett was composed of three grains of the iodide to an ounce of lard. The dose is an eighth of a grain (0·008 Gm.) three times a day, in pill or solution.

* "Take of Arsenic *sixty grains;* Iodine *three hundred grains*. Rub the Arsenic in a mortar until reduced to a fine powder; then add the Iodine, and rub them together until they are thoroughly mixed. Put the mixture into a small flask or a test-tube, loosely stopped, and heat it very gently until liquefaction occurs. Then incline the vessel in different directions, in order that any portion of the iodine, which may have condensed on its surface, may be returned into the melted mass. Lastly, pour the melted iodide on a porcelain slab, and, when it is cold, break it into pieces, and keep it in a well-stopped bottle." *U. S.* 1870.

ARSENUM. Arsenic.

As; 74·9. (ĂR'SĒ-NŬM.) As; 75.

Arsenicum, *U.S.* 1870; Arsenum, Arsenium; Arsenic, *Fr.;* Arsenik, *G.;* Arsenico, *It., Sp.*

This metal was introduced into the U. S. and Dublin Pharmacopœias in 1850, for the purpose of being used to form arsenic iodide, and the solution of arsenic and mercury iodide, at that time two new salts of those works. It has been rejected by the compilers of the U. S. Pharmacopœia and the British. The Dublin College gave the following formula:

"Take of White Oxide of Arsenic of Commerce two drachms [*Dub. weight*]. Place the Oxide at the sealed end of a hard German glass tube, of about half an inch in diameter and eighteen inches long, and, having covered it with about eight inches of dry and coarsely pulverized charcoal, and raised the portion of the tube containing the charcoal to a red heat, let a few ignited coals be placed beneath the Oxide, so as to effect its slow sublimation. When this has been accomplished, the metallic arsenic will be found attached to the interior of the tube at its distant or cool extremity.

"In conducting this process, the furnace used in the performance of an organic analysis should be employed, and the fuel should be ignited charcoal. It will be proper also to connect the open extremity of the tube with a flue, for the purpose of preventing the possible escape into the apartment of arsenical vapors; and, with the view of keeping it from being plugged by the metal, to introduce occasionally into it, as the sublimation proceeds, an iron wire through a cork, fixed (but not air-tight) in its open extremity."

In the above process, the white oxide (arsenous oxide) is reduced by the agency of ignited charcoal, which attracts the oxygen of the oxide, and revives the metal. On the large scale, metallic arsenic is generally obtained by heating arsenical pyrites ($FeAs,FeS_2$) in earthen tubes; when the metal sublimes, and two mols. of ferrous sulphide, FeS, are left.

Properties. Arsenic is a brittle, crystalline metal, of a steel-gray color, and possessing much brilliancy when recently broken or sublimed. Exposed to the air, its surface becomes dull and blackish. Its texture is granular, and sometimes a little scaly. Rubbed on the hands, it communicates a peculiar odor; but it is devoid of taste. Its sp. gr. is about 5·73 (5·88, *U. S.*). When heated to about 180° C. (356° F.) it sublimes, giving rise to white vapors having a garlicky odor.* Its atomic weight is 74·9. It forms two combinations with oxygen, arsenous and arsenic oxides, As_2O_3 and As_2O_5 respectively, to each of which the corresponding acid is known, and three with sulphur, namely, the disulphide, or realgar, As_2S_2; the trisulphide, or orpiment, As_2S_3, corresponding in composition to arsenous oxide; and the pentasulphide, As_2S_5, corresponding to arsenic oxide. (See *Acidum Arsenosum;* also *Realgar* and *Orpiment* in PART II. of this work.) *Arsenic oxide* is obtained by distilling off a mixture of twelve parts of nitric and one of hydrochloric acid from four parts of arsenous acid, until the whole acquires the consistence of a thin syrup. The liquid is then poured into a porcelain dish, and evaporated at a moderate heat. Suddenly the arsenic oxide concretes into an opaque white mass, which should be transferred, while warm, to a well-stopped bottle. Arsenic oxide is white, solid, deliquescent, and soluble in six parts of cold and two of boiling water. It forms several acids, corresponding to the several varieties of phosphoric acid, to which it bears a close analogy. With silver nitrate it gives a brick-red precipitate of silver arsenate. As a poison it is even more virulent than arsenous oxide. It consists of two atoms of arsenic and five of oxygen (As_2O_5).

The world's supply of arsenic and arsenic compounds at the present time is obtained from Germany and England. The German production of crude arsenic (including arsenous oxide) for 1895 amounted to 3005 metric tons, valued at $207,189; for England, in the same year, 4875 metric tons, valued at $260,990.

Arsenic is much diffused. Besides being present in a great many minerals, it has been detected, in minute proportion, in the earth of graveyards by Orfila; in certain soils and mineral waters by M. Walchner; in the ashes of various plants by M. Stein; in various mineral coals; also in the incrustation formed in the boiler of a sea-going steamer, by M. Daubrée.

* The statement that arsenic on being heated sufficiently passes at once into the state of vapor without fusing was disproved by experiments of Dunnington and Odger, made under the direction of Prof. Mallet, of the University of Virginia. They succeeded in fusing arsenic without great difficulty. (*Chem. News*, Aug. 30, 1872.)

ASAFŒTIDA. U. S. (Br.) Asafetida.

"A gum-resin obtained from the root of Ferula fœtida (Bunge), Regel (nat. ord. Umbelliferæ)." *U. S.* "A gum-resin obtained by incision from the root of Ferula fœtida, Regel; and probably other species." *Br.*

Asafetida, *Br.;* Cibus Deorum; Gummi-resina Asafœtida: Asse-fétide, Assafœtida, *Fr.;* Stinkasant, Teufelsdreck, *G.;* Assafetida, *It.;* Asafetida, *Sp.;* Ungoozeh, *Pers.;* Hilteet, *Arab.;* Stercus Diaboli, *L.*

Concerning the genus Ferula there has been much dispute by botanists, but at present a much wider range is given to it than formerly. H. Falconer (*Trans. Linn. Soc.*, xx. 285) separated from it the genus *Narthex*, relying chiefly upon the distinctness of the vittæ as characteristic, whilst Bunge separated the genus *Scorodosma* on account of the absence of vittæ. According, however, to Bentham and Hooker, the vittæ in Bunge's type specimens are no more inconspicuous than in various other species of the genus; and, further, the vittæ vary so much that no generic character can be drawn from them. The genus Ferula is a very difficult one to characterize briefly, and for its description the reader is referred to Bentham and Hooker, *Genera Plantarum*, i. 917.

Ferula fœtida. Regel. *F. scorodosma.* Bentham and Hooker. *Scorodosma fœtidum.* Bunge. *Ferula assafœtida*, L., of Boissier, *Flora Orientalis*, ii. 994, is a coarse umbelliferous plant, growing from five to seven feet high, with a large fleshy root, the crown of which is covered with coarse bristly fibres, and gives origin to large bipinnate radicle leaves and a nearly naked stem which has only a few bipinnate leaves without wide sheathing petioles, and ends at the top in very numerous umbels. The flat-winged fruit have the vittæ almost obsolete. This plant was first discovered in the sandy desert near the sea of Aral, by Lehmann, in 1844. Bunge found it in Persia about twenty years later. It would seem to be native all through Afghanistan.

Ferula assafœtida. Willd. *Sp. Plant.* i. 1413. *B. & T. Ferula narthex.* Bois. *Narthex assafœtida.* Falconer. This plant, which was formerly recognized officially as a source of asafetida, was first described from actual observation by H. Falconer, who found it near Kashmir, and has long been successfully cultivated in the Edinburgh Botanical Gardens. It is distinguished from the true asafetida plant by the greater height of the stem (6 to 10 feet), and by the numerous stem leaves furnished with wide sheathing petioles. The flowers are pale yellow, and the oval fruit thin, flat, foliaceous, and reddish brown, with pronounced vittæ. It yields a milky juice having a powerful smell of asafetida.

It is possible that asafetida is obtained from several species of umbelliferous plants, although it seems to be determined that the official plant yields the bulk of it. This plant does not agree with the figures given by Engelbert Kaempfer of the plant which he observed in 1687, and to which he gave the name of *Assafœtida disgunensis*, although Falconer considers the latter plant as identical with his *Narthex assafœtida*, and Borszczon, who studied *F. scorodosma*, growing wild in the neighborhood of the Caspian Sea, believes this plant the same as that of Kaempfer. It is very likely that the difficulty of identification is due to inaccuracies in the original figure of Kaempfer. *F. persica* is also said to produce an asafetida-like gum-resin, and was recognized by the Edinburgh Pharmacopœia. *Ferula Jæschkeana*, Vatke, which has been believed to be the source of asafetida, according to E. M. Holmes, has, at least in its dried state, not the slightest odor of asafetida, and indeed yields a strongly celery-scented juice. (*Ph. Jr.*, 1894, xxv.)

The oldest plants are most productive, and those under four years old are not considered worth cutting, according to the statement of Kaempfer in 1687. At the season when the leaves begin to fade, the earth is removed from about the top of the root, and the leaves and stem, being twisted off near their base, are thrown with other vegetable matters over the root, in order to protect it from the sun. After some time the summit of the root is cut off transversely, and, the juice which exudes having been scraped off, another thin slice is removed, in order to obtain a fresh surface for exudation. This process is repeated at intervals till the root ceases to afford juice, and perishes. During the whole period of collection, which occupies nearly six weeks, the solar heat is as much as possible excluded. The juice collected from numerous plants is put together, and allowed to harden in the sun. Dr. H. W. Bellew visited Kandahar in 1872, and witnessed the collection of the drug; he describes the process essentially as did Kaempfer. The roots varied in size from that of a carrot to the thickness of a man's leg, and their yield from half an ounce to two pounds. The drug, he states, is very much

adulterated. The fruit is said to be sent to India, where it is highly esteemed as a medicine. In 1884 Afghanistan was visited by Dr. J. E. T. Aitchison, who found the plains having an altitude of 2000 to 4000 feet, arid and bare in winter, but in the early summer covered with a thick growth of *Ferula fœtida*, *Dorema ammoniacum*, and *Ferula galbaniflua*. The great cabbage-like heads of the asafetida plant, representing the primary stage of the flower-heads covered over by the stipules of its leaves, are eaten raw by the natives as a sort of green. In June the asafetida is obtained. The root-stock is first laid bare to the depth of a couple of inches, those plants only which have not reached their flower-bearing stage being selected. A slice is then taken from the top of the root-stock, which is immediately covered with twigs and clay, forming a sort of dome, with an opening towards the north, so that the sun cannot get at the exposed root. About five or six weeks later, a thick, gummy, not milky, reddish substance found upon the exposed surface of the root in more or less irregular lumps is scraped off with a piece of iron hoop or removed with a slice of the root and at once placed in a leather bag. The asafetida is conveyed to Herat, where it is adulterated with red clay before being sent into commerce. It is brought to this country either from India, whither it is conveyed from Bushire and down the Indus, or by the route of Great Britain. It sometimes comes in mats, but more frequently in cases, the former containing eighty or ninety pounds, the latter from two hundred to four hundred pounds. It is sometimes also imported in casks.

Properties. As found in commerce, asafetida is in irregular masses, softish when not long exposed, of a yellowish or reddish-brown color externally, exhibiting when broken an irregular, whitish, somewhat shining surface, which soon becomes red on exposure, and ultimately passes into a dull yellowish brown. This change of color is characteristic of asafetida, and is ascribed to the influence of air and light upon its resinous ingredient. The masses appear as if composed of distinct portions agglutinated together, sometimes of white, almost pearly tears, embedded in a darker, softer, and more fetid paste. Occasionally the *tears* are separate, though rarely in the commerce of this country. They are roundish, oval, or irregular, and generally flattened, from the size of a pea to that of a large almond, sometimes larger, yellowish or brownish externally and white within, and not unlike ammoniac tears, for which they might be mistaken except for their odor, which, however, is weaker than that of the masses. A very fine variety of asafetida is spoken of by Bellew as being procured from the leaf-bud in the centre of the root. It does not come into European commerce, but is the *Kandaharee Hing* of the Indian bazaars. (*P. J. Tr.*, viii. 103.) It occurs in moist flaky pieces and tears, yielding a reddish-yellow oil on pressure, and mostly mixed with the remains of leaf-buds. The odor of asafetida is alliaceous, fetid, and tenacious; the taste, bitter, acrid, and durable. The effect of time and exposure is to render it more hard and brittle, and to diminish the intensity of its smell and taste, particularly the former. Kaempfer assures us that one drachm of the fresh juice diffuses a more powerful odor, through a close room, than one hundred pounds of the drug as usually kept in the stores. The color, which is at first white, becomes pink, and finally the well-known brown, on exposure. Asafetida softens by heat without melting, and is of difficult pulverization. Its sp. gr. is 1·327. (*Berzelius.*) It is inflammable, burning with a clear, lively flame. It yields all its virtues to alcohol, and forms a clear tincture, which becomes milky on the addition of water. "When triturated with water, it yields a milk-white emulsion, which becomes yellow on the addition of ammonia water. It is partly soluble in ether, and at least 60 per cent. of it should dissolve in alcohol." *U. S.* Macerated in water it produces a turbid red solution, and triturated with that fluid it gives a white or pink-colored milky emulsion of considerable permanence. Touched with nitric acid (sp. gr. 1·2) the tear becomes of an evanescent green color. "If a small fragment be strongly heated in a dry test-tube, the contents of the tube, after cooling, yield with boiling *water* a solution which when largely diluted and made alkaline with *solution of ammonia* exhibits a blue fluorescence." *Br.* In 100 parts, Pelletier found 65 parts of resin, 19·44 of gum, 11·66 of bassorin, 3·60 of volatile oil, with traces of acid calcium malate.* "Asafetida should contain

* J. Polásek examined the pure tears of *Asafœtida amygdaloides*, finding the following constituents: 61·40 per cent. of resin soluble in ether, which is regarded by him to be the ferulaic acid ester of asaresino-tannol; 0.60 per cent. of resin insoluble in ether, regarded to be free asaresino-tannol; 25·10 per cent. of gum; 6·70 per cent. of volatile oil; 0·06 per cent. of vanillin; 1·28 per cent. of free ferulaic acid; 2·36 per cent. moisture; 2·50 per cent. impurities. *Asaresino-tannol* has the composition corresponding to the formula $C_{24}H_{35}O_5$. The author has prepared a benzoyl derivative, $C_{24}H_{33}O_5.C_6H_5CO$, and an acetyl derivative, $C_{24}H_{33}O_5.CH_3CO$, which prove it to contain a hydroxyl group,—viz., $C_{24}H_{33}O_4.OH$. Umbelliferone was obtained as a secondary product of hydrolysis with sulphuric acid from asaresino-tannol, and was also obtained from ferulaic acid synthetically, guaiacol being produced at the same time. By nitrification of asaresino-tannol, picric acid is produced. (*Arch. d. Pharm.*, 235 (March, 1897), 125–132.)

not less than 65 per cent. of matter soluble in *alcohol* (90 per cent.), and should yield not more than 10 per cent. of ash when incinerated." *Br.* The odor of the gum-resin depends on the *volatile oil*, which may be procured by distillation with water or alcohol, and amounts to from 6 to 9 per cent., according to Flückiger. It is lighter than water, colorless when first distilled, but becoming yellow with age, of an exceedingly offensive odor, and of a taste at first flat, but afterwards bitter and acrid. It contains, according to Stenhouse, from 15·75 to 23 per cent. of sulphur; but, according to Flückiger, it may contain as much as 25 per cent. Hlasiwetz (*Ann. Chem. und Pharm.*, 71, 23) considers it a mixture, in variable proportions, of the sulphide and bisulphide of a compound radical consisting of carbon and hydrogen (C_6H_{11}). Allyl persulphide, which is sublimed when oil of mustard is heated with potassium persulphide, is said by Wertheim to have an extremely intense odor of asafetida; a fact which justifies the supposition that it may be identical with the oil of that gum-resin. (*Gmelin*, ix. 377.) The oil boils at about 138° C. (280° F.), but suffers decomposition, yielding hydrogen sulphide. When long exposed to the air it becomes slightly acid, and acquires a somewhat different odor. (*Chem. Gaz.*, No. 178.)

The resin is, according to Hlasiwetz and Barth (*Ann. Chem. und Pharm.*, 138, 61), a mixture containing *ferulaic acid*, $C_{10}H_{10}O_4$, crystallizing in iridescent needles, and obtained by precipitating the alcoholic solution with lead acetate, washing the precipitate, and decomposing it with diluted sulphuric acid. Submitted to dry distillation, the resin yields *umbelliferone*, $C_9H_6O_3$, and blue-colored oils. Fused with caustic potash, ferulaic acid yields oxalic acid and carbonic acid, several acids of the fatty series, and protocatechuic acid. The resin itself treated in like manner, after it has been freed from gum, yields resorcin.

Impurities and Adulterations. Asafetida is often purposely adulterated; it frequently comes of inferior quality, and mixed with various impurities, such as sand and stones. Portions which are very soft, dark brown, or blackish, with few or no tears, and indisposed to assume a red color when freshly broken, should be rejected. We have been informed that a case seldom comes without more or less of this inferior asafetida, and of many it forms the larger portion. It is sold chiefly for horses. A factitious substance, made of garlic juice and white pitch with a little asafetida, has occurred in commerce. Asafetida is said to be usually mixed with wheat or barley flour or with earthy matters at the place of its production, the impurities sometimes exceeding 30 per cent. *Hingra* of the Bombay bazaars is a very stony variety, composed largely of earthy matter.

Prof. J. U. Lloyd, after examining a large number of samples of commercial asafetida, was convinced that it is impracticable to obtain the crude drug of the official standard; gypsum, carbonates, and other insoluble matters being present in large amounts. He did not find white turpentine or rosin in any of the samples; exhausting asafetida with alcohol and evaporating the alcohol carefully, he obtained an extract for which he proposed the name of *Purified Asafetida.* (*Pharm. Rev.*, 1896.)

Asafetida is sometimes kept in a powdered state; but this is objectionable, as the drug is thus necessarily weakened by the loss of volatile oil, and is more liable to adulteration.

Medical Properties and Uses. Asafetida acts as a stimulant antispasmodic, efficient expectorant, and feeble laxative. Some consider it also emmenagogue and anthelmintic. Its volatile oil is undoubtedly absorbed, as its peculiar odor may be detected in the breath and the secretions. As an antispasmodic, it is employed in the treatment of *hysteria*, *hypochondriasis*, *convulsions* of various kinds, *spasm of the stomach and bowels* unconnected with inflammation, and in numerous other nervous disorders of a merely functional character. From the union of expectorant with antispasmodic powers, it is highly useful in *spasmodic pectoral affections*, such as *whooping-cough* and *asthma*, and in certain *infantile coughs* and *catarrhs*, complicated with nervous disorder, or with a disposition of the system to sink. In *catarrhus senilis;* in the secondary stages of *peripneumonia notha*, *croup*, *measles*, and *catarrh;* in *pulmonary consumption;* in fact, in all cases of *subacute* or *chronic disease of the chest* in which there is want of due nervous energy, asafetida may be occasionally prescribed with advantage. In the form of enema, it is useful in cases of *inordinate accumulation of air in the bowels*, and also in the *hysteric paroxysm* and other functional convulsions. Its laxative tendency is often advantageous, and it may be usefully combined with cathartics in *flatulent constipation.*

It appears to have been known in the East from very early ages, and, notwithstanding its repulsive odor, is at present much used in India and Persia as a condiment. Persons soon habituate themselves to its smell, which they even learn to associate pleasantly with the agreeable effects experienced from its internal use. Children with whooping-cough sometimes become fond of it.

The medium dose is ten grains (0·65 Gm.), which may be given in pill or emulsion. The tincture is official, and is much used. When given by injection, the gum-resin should be triturated with warm water. From half a drachm to two drachms (1·95–7·8 Gm.) may be administered at once in this way. It may also sometimes be conveniently given in the form of a suppository.* A syrup has been recommended in which the fetid odor of the drug is obviated by the use of the infusion of wild cherry bark. (See *A. J. P.*, 1871, p. 397.)†

ASCLEPIAS. U. S. Asclepias. [Pleurisy Root.]

(ĄS-CLĒ'PĮ-ĄS.)

"The root of Asclepias tuberosa, Linné (nat. ord. Asclepiadeæ)." *U. S.*

Butterfly-Weed; Racine d'Asclépiade tubereuse, *Fr.*; Knollige Schwalbenwurzel, *G.*

Gen. Ch. Calyx small, five-parted. *Corolla* rotate, five-parted, mostly reflexed. *Staminal crown* (or nectary) simple, five-leaved; leaflets opposite the anthers, with a subulate averted process at the base. *Stigmas* with the five angles (corpuscles) opening by longitudinal chinks. *Pollinia* five distinct pairs. *Torrey.*

Several species of Asclepias besides *A. tuberosa* have been employed medicinally: *A. syriaca* and *A. incarnata* were recognized in the Secondary Catalogue U. S. Pharm. 1870.

A. incarnata, or *Flesh-colored Asclepias*, has an erect, downy stem, branched above, two or three feet high, and furnished with opposite, nearly sessile, lanceolate, somewhat downy leaves. The flowers are red, sweet-scented, and disposed in numerous crowded erect umbels, which are generally in pairs. The nectary is entire, with its horn exserted. In one variety the flowers are white. The plant grows in all parts of the United States, preferring a wet soil, and flowering from June to August. Upon being wounded it emits a milky juice. Dr. Griffith states that the root is a useful emetic and cathartic. (*Journ. of the Phila. Coll. of Pharm.*, iv. 283.) Dr. Gram has found in the *Asclepias curassavica*, *A. incarnata*, *A. vincetoxicum*, *A. officinale*, a glucoside, *asclepiadin*, which he believes to be a pure form of the asclepiadin of Harnack and the asclepin of Feneulle, and closely to resemble emetine in its physiological action, but to be so unstable as to be of no practical value. From *A. vincetoxicum* M. Tanret (*Compt.-Rend.*, c. 277) has isolated two glucosides, soluble and insoluble *vincetoxin*, with the formula $C_{18}H_{12}O_6$. The soluble vincetoxin is a clear yellow amorphous powder, easily soluble in water, alcohol, and chloroform, insoluble in ether. It begins to decompose at 130° C. The insoluble vincetoxin dissolves readily in alcohol, chloroform, and ether, but in water only in the presence of the soluble vincetoxin. It fuses at 59° C. Decomposed by dilute acids, they each yield an uncrystallizable, inactive, unfermentable sugar. An indigenous species, *A. verticillata*, is used in the Southern States as a remedy in *snake-bites* and the *bites of venomous insects*. Three gills of a saturated decoction are said to cause an anodyne and sudorific effect, followed by a gentle sleep. (*Va. Med. Journ.*, Dec. 1858.)

A. syriaca. Willd. *A. cornuti* (Decaisne, *Gray's Manual*). *Common Silk-weed*, or *Common Milk-weed*, has simple stems, from three to five feet high, with opposite, lanceolate-oblong, petiolate leaves, downy on their under surface. The flowers are large, of a pale-purple color, sweet-scented, and arranged in two or three nodding umbels. The nectary is bidentate. The pod or follicle is covered with sharp prickles, and contains a large quantity of silky seed-down. It is very common in the Middle United States. It flowers in July and August. Its milky juice has a faint smell, a sub-acrid taste, and an acid reaction. According to Schultz, 80 parts of it contain 69 of water, 3·5 of a wax-like fatty matter, 5 of caoutchouc, 0·5 of gum, 1 of sugar with salts of acetic acid, and 1 of other salts. (*Pharm. Centralblatt*, 1844, p. 302.) Dr. C. List found the chief solid ingredient of the juice to be a peculiar resinous crystalline substance (*asclepion*, $C_{20}H_{34}O_3$) allied to lactucon. To obtain it, the juice is coagulated by heat, filtered, and the filtrate digested with ether, which dissolves the asclepion, and yields it by

* *Emplastrum Asafœtidæ.* The U. S. Pharmacopœia formerly recognized a plaster of asafetida, which is sometimes used locally in *hysteria, pneumonia, convulsions* in children, etc. It was prepared as follows. "Asafetida, *thirty-five parts* [or thirteen ounces av.]; Lead Plaster, *thirty-five parts* [or thirteen ounces av.]; Galbanum, *fifteen parts* [or five and a half ounces av.]; Yellow Wax, *fifteen parts* [or five and a half ounces av.]; Alcohol, *one hundred and twenty parts* [or three pints]. Digest the Asafetida and Galbanum with the Alcohol on a water-bath, separate the liquid portion, while hot, from the coarser impurities by straining, and evaporate it to the consistence of honey; then add the Lead Plaster and the Wax, previously melted together, stir the mixture well, and evaporate to the proper consistence." *U. S.* 1880.

† J. W. Wood prepares *syrup of asafetida* by dissolving 256 grains of asafetida in two fluidounces of glycerin by the aid of a gentle heat, and straining. He then dissolves 15 drops oil of wintergreen, 5 drops oil of cinnamon, and 1 drop oil of bitter almond, in three fluidrachms of 95 per cent. alcohol, and adds to it the above, together with enough simple syrup to make one pint. Each fluidrachm represents two grains of asafetida. (*A. J. P.*, 1874.)

evaporation. To purify it, the residue must be treated repeatedly with anhydrous ether, which leaves another substance undissolved. It is white, crystalline, tasteless, inodorous, fusible, insoluble in water and alcohol, soluble in ether, oil of turpentine, and concentrated acetic acid. A strong hot solution of potassa does not affect it. (*Liebig's Annalen*, Jan. 1849.) Hinchman examined *A. cornuti* in 1881, and found asclepion, caoutchouc, fixed oil, tannin, glucose, a bitter principle, gum, starch, volatile oil, and ash. (*A. J. P.*, liii. p. 435.) Anodyne, cathartic, and alterative properties have been claimed for the root of this plant, and it has been especially commended in *asthma* and in *scrofula*, but probably is of very little medical value. A drachm of it in decoction may be given two or three times a day.

Asclepias tuberosa. Willd. *Sp. Plant.* i. 1273; Bigelow, *Am. Med. Bot.* ii. 59; Barton, *Med. Bot.* i. 239. The root of the butterfly-weed, or *pleurisy root*, is perennial, and gives origin to numerous stems, which are erect, ascending, or procumbent, round, hairy, of a green or reddish color, branching at the top, and about three feet in height. The leaves are scattered, oblong-lanceolate, very hairy, of a rich deep-green color on their upper surface, paler beneath, and supported usually on short footstalks. They differ, however, somewhat in shape according to the variety of the plant. In the variety with decumbent stems they are almost linear, and in another variety cordate. The beautiful reddish-orange-colored flowers occur in terminal or lateral corymbose umbels. The fruit is an erect lanceolate follicle, with flat ovate seeds connected to a longitudinal receptacle by long silky hairs.

This plant differs from other species of Asclepias in not emitting a milky juice when wounded. It is indigenous, growing throughout the United States from Massachusetts to Georgia, and as far west as Texas, and when in full bloom, in June and July, having a splendid appearance. It is most abundant in the Southern States. The root is the only part used in medicine. It is "large and fusiform, dried in longitudinal or transverse sections, from 2 to 15 Cm. long, and about 2 Cm. or more in thickness; the head knotty, and slightly but distinctly annulate, the remainder longitudinally wrinkled, externally orange-brown, internally whitish; tough, and having an uneven fracture; bark thin, and in two distinct layers, the inner one whitish; wood yellowish, with large, white, medullary rays. It is inodorous, and has a bitterish, somewhat acrid taste. When long kept it acquires a gray color." *U. S.*

When dried, it is easily pulverized; and its taste is bitter, but not otherwise unpleasant. Mr. E. Rhoads discovered in it a peculiar principle, which he obtained by treating the cold infusion with tannic acid, mixing the precipitate, previously washed and expressed, with litharge, drying the mixture and exhausting it with hot alcohol, and finally decolorizing and evaporating the alcoholic liquor. The product was a yellowish-white powder, having the taste of the root, soluble in ether, and much less readily so in water, from which it was precipitated by tannic acid. Mr. Rhoads also found evidence of the existence in the root of tannic and gallic acids, albumen, pectin, gum, starch, a resin soluble and another insoluble in ether, fixed oil, a volatile odorous fatty matter, and various salts, besides from 30 to 35 per cent. of lignin. (*A. J. P.*, xxxiii.) Quackenbush (*A. J. P.*, 1889) found in it and also in *A. cornuti* a crystalline glucoside.

Medical Properties and Uses. The root of *Asclepias tuberosa* is diaphoretic and expectorant, and in sufficient dose cathartic. In the Southern States it has long been employed by regular practitioners in *catarrh*, *pneumonia*, *pleurisy*, *consumption*, and other pectoral affections. It is said to be gently tonic, and has been popularly used in *pains of the stomach* from flatulence and indigestion. From twenty grains to a drachm (1·3–3·9 Gm.) of the root in powder may be given several times a day; but as a diaphoretic it is best administered in decoction, an ounce to a quart; dose, a teacupful every two or three hours till it operates.

ASPIDIUM. U. S. (Br.) Aspidium. [Male Fern.]

(ĄS-PĬD'Ị-ŭM.)

"The rhizome of Dryopteris Filix-mas, Schott, and of Dryopteris marginalis, Asa Gray (nat. ord. Filices)." *U. S.* "The rhizome of Aspidium Filix mas, Swartz. Collected late in the autumn, divested of its roots, leaves, and dead portions, and carefully dried. Should not be used if more than a year old." *Br.*

Filix Mas, *Br.* and *U. S.* 1870; Rhizoma Filicis, *P. G.;* Radix Filicis maris, Male Shield Fern; Fougère mâle, *Fr.;* Wurmfarnwurzel, Woldfarnwurzel, Johanniswurzel, *G.;* Felce maschia, *It.;* Helecho, *Sp.*

Gen. Ch. Fruit dots roundish or round, borne on the backs or extremities of free pinnate veins; indusium flat, scarious, orbicular, or round kidney-shaped, covering the sporangia, attached to the receptacle at the centre, or at the sinus opening all round the margin.

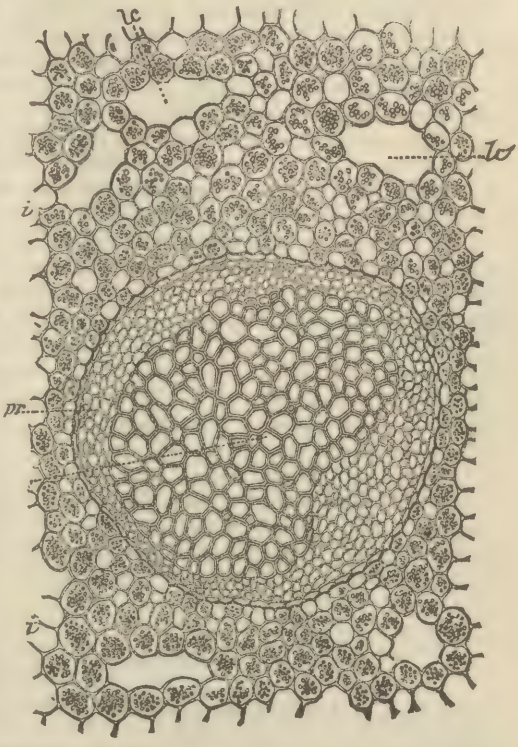
As the term Dryopteris was first used by Amman in 1739, and was again applied by Adan-

son in 1763, as the name of the genus which has been commonly known as Aspidium by botanists, the revisers of the U. S. Pharmacopœia are at least theoretically correct in using the term; although some may doubt the wisdom of disturbing a name so thoroughly established as Aspidium, especially in view of the fact that the word "Dryopteris" has been used for the sub-genus of Aspidium, to which the official species belongs,—namely, that in which the indusium is fixed at the narrow sinus, and the fronds are membranous or thin.*

The male fern has a perennial, horizontal root or rhizome, from which numerous annual fronds or leaves arise, forming tufts from a foot to four feet in height. The stipe, or footstalk, and midrib are thickly beset with brown, tough, transparent scales; the frond itself is oval-lanceolate, acute, pinnate, and of a bright-green color. The pinnæ or leaflets are remote below, approach more nearly as they ascend, and run together at the summit of the leaf. They are deeply divided into lobes, which are of an oval shape, crenate at the edges, and gradually diminish from the base of the pinna to the apex. The fructification is in small dots on the back of each lobe, placed in two rows near the base, and distant from the edges. The plant is a native of Europe, Asia, and the north of Africa. It is also said to have been found in some of the Polynesian islands, and grows in Canada, following the Rocky Mountain chain through Mexico, Venezuela, etc., as far south as Peru. In the Eastern United States it is replaced by *A. marginale*, Sw., and *A. goldianum*, Hook.

A. marginale. Swartz. (*Gray's Manual.*) Frond ovate-oblong in outline (one to two feet long), pale green; pinnæ lanceolate, from a broad almost sessile base; pinnules oblong, obtuse, crowded. This species differs from *A. filix mas* chiefly in having its fruit dots upon the margins of its evergreen fronds.†

The revisers of our Pharmacopœia have perhaps acted prematurely in admitting *Dryopteris marginale*, but it is probable that most species of the genus, if not of the natural order, are medicinally active. Mr. J. L. Patterson (*A. J. P.*, 1875) found that the newly-recognized *A. marginale* contained all of the active principle of *A. filix mas*, and Mr. Chas. H. Cressler has demonstrated the activity of its oleoresin. (*Ibid.*, 1878.) On the Pacific slope the indigenous *A. rigidum* is locally used against the tape-worm, and Mr. W. J. Bowman has found in it filicic acid and resin. Popular belief has long ascribed tænicidal virtues to our native *Asplenium filix fœmina;* and the Kaffirs of South Africa use the rhizome of *Aspidium athamanticum* under the name of *inkomankomo*, or *uncomocomo*. It is the *pannum* of European commerce. (*P. J. Tr.*, xvi. 447.) According to R. Kürsten (*P. J. Tr.*, xxii., 1891), the active principle of pannum is closely allied to filicic acid, from which it differs in being especially soluble in strong alcohol, in subliming at 80° C., and in not yielding isobutyric acid when heated in a sealed tube with water. *Pannic* acid crystallizes in thin, shining, light yellow, rectangular prisms, melting at 187° C. (368·6° F.).



* The synonymes of the male fern are extraordinarily numerous. We append some of them: *Aspidium filix mas*, of many authors; *Polypodium filix mas*, Linn.: *Polystichum filix mas*, Roth.: *Nephrodium filix mas*, Rich.; *Lastrea filix mas*, Presl.: *Tectarea filix-mas*, Cavan: *Dryopteris filix-mas*, Schott: *Lophodium filix-mas*, Newm.; *Polypodium nemorale*, Salisb.; *Polystichum durum et induratum*, Schur.; *Polystichum abbreviatum*, De Candolle; *Aspidium mildeanum*, Göppert; *Dryopteris affinis; Polypodium heleopteris.*

† *Botanical Nomenclature.* We think the botanical nomenclature in the U. S. Pharmacopœia of 1890 has somewhat unfortunately been adopted to suit the views of certain botanists who have been recently attempting to radically revise botanical nomenclature. In accordance with the rules adopted by an international congress held in Paris in 1867, the first name applied to any plant, species, or genus must be adopted for the genus and species, provided that the generic name has been given previous to 1737, and the specific name previous to 1753. It is plain, however, that these rules are arbitrary and involve certain absurdities, and that the attempt to carry them out strictly must introduce great confusion into botanical nomenclature, involving the rearrangement or renaming of the herbaria of the world, and much use of printer's ink and confusion of thought. The rules would require us to call the fennel plant *Fœniculum fœniculum;* the sassafras plant, *Sassafras sassafras;* and so on. The confusion which results from these rules, and the absurdity of the rules, are further shown by the genus *Calceolaria*. According to Fifer's *Nomenclator Botanicus*, the name Calceolaria was given in 1725 to a *Scrophulariaceous* genus, and was adopted as the name of that genus by Linnæus in 1771. It would seem, however, that in 1758, Loefling gave the name Calceolaria to a genus of *Violacea*. It is plain that Calceolaria was first applied to the *Scrophulariaceous* genus; but, because the first application was made previous to 1737, the name must, according to the rules, be applied to the genus of violets, and it is so applied by the school of botanists already spoken of. (See *Annals of New York Academy*, 1893, p. 51.) It so happens that the world over the name *Calceolaria* has for one hundred and twenty-five years been used for the Scrophulariaceous group, and for one hundred years or so *Ionidium* has been employed for the group of violets. Now, forsooth, the rights of priority are to be thrown aside, the universal custom of over a century overthrown, all the world's herbaria rearranged, books rewritten, and confusion in general to reign, because gentlemen in 1867, in the city of Paris assembled, chose to say, We will make a set of arbitrary rules! In our opinion so long as the authoritative botanical works, like *Gray's Manual*, adopt a certain botanical nomenclature, the Pharmacopœia should cling to general custom, and not be led into the disputed and barren territory of botanical revision in nomenclature. Of course, in drug definitions the Pharmacopœial botanical nomenclature must be adhered to; but we can see no sufficient reason for changing the nomenclature in the U. S. Dispensatory.

Heffter (*Archiv f. Exp. Path. u. Pharm.*, 1897, 458) finds three well-characterized and crystallized principles in pannum: *flavopannin*, $C_{21}H_{26}O_7$, crystallizing in citron-yellow prisms, melting at 151° C., and soluble in ether, benzene, acetic ether, acetone, and boiling methyl and ethyl alcohols, insoluble in petroleum ether and water; *albopannin*, $C_{21}H_{24}O_7$, crystallizing in silky-white needles, which melt at 147° C.; and *pannol* (pannic acid of Kürsten), $C_{11}H_{14}O_4$, fusing at 192° C., which is easily soluble in hot glacial acetic acid and acetone, more difficultly soluble in alcohol and ether, and very slightly soluble in petroleum ether, benzene, and water. The alcoholic solution is colored intensely dark green with ferric chloride. Heffter compares these three compounds with the three obtained from *A. filix*, and finds a close chemical and therapeutic correspondence between aspidin and flavopannin, between albaspidin and albopannin, and between aspidinol and pannol. According to the experiments of A. Heffter, both *flavopannin* and *albopannin* are powerful muscle poisons, directly affecting the heart. (*Arch. f. Exp. Path. u. Pharm.*, Bd. xxxviii)

According to M. Peschier, of Geneva, aspidium deteriorates rapidly when kept, and in about two years becomes entirely inert. The rhizomes of other species of fern are frequently substituted for the official; and in the dried state it is difficult to distinguish them. The chaff, together with the dead portions of the rhizome and stipes, should be removed, and only such portions as have retained their green color should be used.

Properties, etc. As taken from the ground, the rhizome consists of a long cylindrical caudex, around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leafstalks or stipes, which are an inch or two in length, from two to four lines thick, somewhat curved and directed upwards, angular, brown, shining, and surrounded near their origin from the rhizome with thin silky scales of a light brown color. From between these remains of the footstalks emerge numerous small radical fibres. The whole rhizome, thus constituted, presents a somewhat flexible, cylindrical mass, one or two inches thick, and from three inches to a foot or more in length. In this form, however, it is not usually found in commerce. The whole is ordinarily broken up into fragments, consisting of the separated remains of the leafstalks before described, with a small portion of the substance of the rhizome attached to their base, where they are surrounded by the silky scales. These fragments, as seen in commerce, often appear as if long kept, and are probably, in general, much deteriorated by time. The following observations are made by Geiger in relation to the collection and preservation of the rhizome. The inner parts of the fresh rhizome, and of the portions of stalk attached to it, are fleshy and of a light yellowish-green color. In collecting them, all the black discolored portions should be cut away, the fibres and scales separated, and only the sound green parts preserved. These should be immediately but carefully dried, and then pulverized; and the powder should be kept in small well-stopped glass bottles. The powder thus prepared has a pale yellowish color with a greenish tinge.

Rhizome of Aspidium. *lc*, open interspace; *pr*, prosenchyma; *i*, parenchyma.

The dried rhizome is "from 5 to 15 Cm. long, 10 to 25 Mm. in thickness, and, together with the closely imbricated, dark brown, roundish, and slightly curved stipe-remnants, 50 to 75 Mm. in diameter; densely covered with brown, glossy, transparent, and soft, chaffy scales; internally pale green, rather spongy." *U. S.* Microscopic examination shows that it is composed of polyhedral, porous-walled cells and vascular bundles containing scalariform ducts: in *A. filix mas* ten of these bundles are larger than the

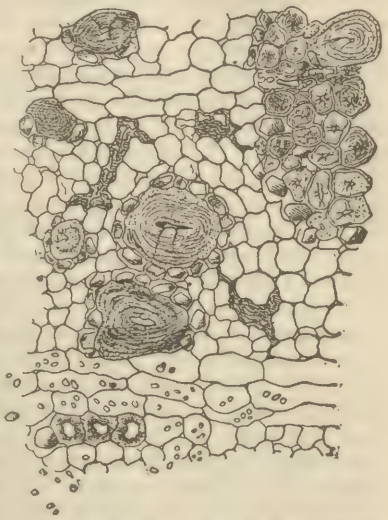
others, and are arranged in an attempted circle near to the surface; whilst in *A. marginale* there are only six bundles in the circle. It has been analyzed by H. Bock, who gives as its constituents volatile oil, fixed oil, resin, starch, vegetable jelly, albumen, gum, sugar, tannic and gallic acids, pectin, lignin, and various salts. (See *A. J. P.*, xxiv. 64.) Peschier ascertained that its active properties reside in the ethereal extract, which is the fixed oil in an impure state, containing volatile oil, resin, coloring matter, etc. It is a thick dark liquid, with the odor of the fern, and a nauseous, bitterish, somewhat acrid taste. Dr. E. Luck has found in it a peculiar acid, which he denominates *filicic acid*, and has extracted from the root two others, named *tannaspidic* and *pteritannic acids*. (*Chem. Gaz.*, ix. 407 and 452.) Luck gave to the filicic acid the formula $C_{13}H_{14}O_4$, but Grabowsky claimed that it should be $C_{14}H_{18}O_5$, and that the acid was in reality *dibutyryl phloroglucin*, $C_6H_4(C_4H_7O)_2O_3$. Daccomo found in male fern (*A. J. P.*, 1889) *filicic acid*, to which he gives the formula $C_{14}H_{16}O_5$, a white waxy substance, melting at 80° C., with the formula $(C_{13}H_{26}O)_n$, glucose, tannin, a red coloring matter (*filix red*), a green oil which he separated into several fractions, and two resins, one brick-red, melting at 85°–93° C., and the other black and plastic. He considers that filicic acid is probably an isobutyric acid derivative of hydroxynaphthaquinone. Poulson (*Archiv f. Exp. Path. u. Pharm.*, 1891) states that, when pure, crystalline, inactive filicic acid is dissolved in alkalies and reprecipitated by an acid, the amorphous precipitate possesses the active properties of the extract. He thinks that the inactive crystalline body is an anhydride or lactone of the amorphous filicic acid, and should be called *filicin*. Kobert believes that the activity of male fern is due partly to volatile oil, one reason being that pure filicic acid given in very large doses was not as effective as a smaller dose of the acid mixed with a portion of the fixed and volatile oils from the male fern. (*Pharm. Post*, 1892, 1325.) For an assay method for male fern extract, see *Am. Drug.*, 1897, 73.

Medical Properties and Uses. Male fern was used by the ancients, and is mentioned as a vermifuge in the works of Dioscorides, Theophrastus, Galen, and Pliny, and by some of the earlier modern writers. But it does not appear to have been generally known till about the year 1775, when the King of France purchased from Madame Nouffer, the widow of a Swiss surgeon, a secret remedy for *tape-worm*, which proved to be the powdered root of the male fern. The oleoresin of male fern is a very efficient tænicide, and is also much used against the anchylostoma. It is, however, in overdose a distinct poison, Drs. Katayama and Okamoto (*Sei-i-kwai*, July, 1892) having collected from literature twenty-two cases of poisoning by it, of which five proved fatal. Six drachms have caused death. (*Lancet*, 1882.) The symptoms have been vomiting, diarrhœa, vertigo, headache, tremor, cold sweat, dyspnœa, cyanosis, mania, coma, convulsions. In nearly half of the cases there was amblyopia, or even amaurosis, with dilated, fixed pupils; the loss of sight is usually temporary, but has proved permanent. Katayama and Okamoto succeeded in producing blindness in the lower animals. They believe that the use of castor oil with the male fern notably increases the absorption of the extract. Prevost and Binet have found that in the lower animals, given hypodermically, the oleoresin produces violent dyspnœa and death from arrest of the heart in systole, and Fröhner has found parenchymatous nephritis in animals fatally poisoned by it. For the expulsion of *tape-worm*, the patient should live upon milk and a little bread for one day, and the following morning take a full dose (f℥ss to f℥i) of the oleoresin, fasting, and repeating it in two or three hours. At noon the patient may resume the use of food, and in the evening a brisk cathartic should be given. Male fern is said (with doubtful accuracy) to prove more effectual against the tape-worm of the Swiss (*Bothriocephalus latus*) than against the *Tænia solium*, which is more frequent in France and England. (*Bremser.*)

ASPIDOSPERMA. U. S. Aspidosperma. [Quebracho.]

(ĂS-PĮ-DŌ-SPĔR'MĄ.)

"The bark of Aspidosperma Quebracho-blanco, Schlechtendal (nat. ord. Apocynaceæ)." *U. S.*



Quebracho Bark, Quebracho Blanco.

The technical characters of the genus *Aspidosperma*, in which are included a number of South American trees, may be found in De Candolle's *Prodromus*, vol. viii. p. 396, or in Hooker's *Genera Plantarum*, vol. ii. p. 702.

Quebracho is an evergreen tree, which sometimes reaches the height of one hundred feet, and is remarkable for its erect stem and its wide-spreading crown reaching out over the cacti and lower bushes among which it grows. The smooth grayish or yellowish branches at the top are more or less erect, whilst below they are horizontal or descending, like those of the

weeping willow. The opposite or ternately verticillate leaves are short petiolate or subsessile, coriaceous, rigid, glaucescent, elliptical-lanceolate. The flower occurs in axillary or terminal sub-cymose panicles; the five-parted, glaucous, campanulate calyx has its segments ovate, acute, whilst the yellowish, five-divided, hypocrateriform corolla has its oblong-linear lobes extended or subinvolute, with an auriculate, sinistrorsely contorted base. The oval, four-angled pollen-grains are smooth and yellowish. The capsules, with the ovule solitary for abortion, are dehiscent into two valves, which are usually medianly subcarinate. The pericarp is thick and woody. The wood of the quebracho tree is not met with in commerce, but is said to be very hard, distinctly marked with rings of growth, and of a bright chocolate-brown color, except the very young wood, which is yellowish or reddish. According to the experiments of Hesse and Penzoldt, the wood is inactive, and contains no alkaloids; it is used for tanning purposes in South America.*

Properties. Quebracho bark is remarkable for the extreme thickness of the corky layer which often constitutes more than half of its entire substance, and is separated from the lower layer by more or less sharply defined outline. The corky layer is usually externally dirty gray, or where it has been rubbed appears yellowish red. As seen with the magnifying glass it is traversed by nearly parallel yellowish lines having numerous whitish points between them. The inner portion of the bark is uniform, except for whitish points. These characteristics of the bark are more plainly observed after moistening the surface. In different specimens the color of the inner bark varies up to light yellow. When examined with high powers the outer layer is seen to be composed of superimposed parenchymatous cells, traversed by bands of small, thick-walled cork cells, constituting the parallel lines before spoken of. The whitish points spoken of are groups of sclerenchymatous cells whose membrane has been so thickened by secondary deposits that the cavity is nearly obliterated. The inner portion of the bark is composed of parenchymatous cells, usually of a cinnamon-brown color, rich in starch, and containing a light-brown granular substance, with groups of sclerenchymatous cells similar to those already spoken of, but containing a dark-yellow substance, which seems to be in drops. These sclerenchymatous cells are more abundant in the inner part of the bark, and are arranged in spindle-shaped fibres, which can be readily separated by scraping the inner surface of the bast. The fibres are surrounded by angular bodies, which on careful examination will be seen to be really a multitude of small cells, each containing a crystal of calcium oxalate. The U. S. P. description of quebracho bark is as follows. "In nearly flat pieces, about 1 to 3 Cm. thick; the outer surface yellowish-gray or brownish, deeply fissured; inner surface yellowish-brown or reddish-brown, distinctly striate; fracture displaying two sharply defined strata, of about equal thickness, and both marked with numerous whitish dots and striæ arranged in tangential lines; the fracture of the outer, lighter colored layer rather coarsely granular, and that of the darker colored, inner layer short-splintery; inodorous; taste very bitter and slightly aromatic."

Section from the inner bark of Quebracho, showing isolated bast cells and a group of sclerenchymatous cells.

Chemical Constituents. In 1878, Fraude (*Ber. der Chem. Ges.*, 1878, p. 2189; 1879, p. 1560) discovered in the quebracho blanco an alkaloid, *aspidospermine*, $C_{22}H_{30}N_2O_2$; but a series of experiments have led Dr. F. Penzoldt to the conclusion that it does not represent the whole medical activity of the bark, and O. Hesse is said to have found five other alkaloids,

* *Quebracho colorado* and *Quebracho Gum* are respectively the wood and the dried juice or watery extract of the *Loxopterygium lorentzii*, a large tree growing in the Argentine Republic. The wood is very heavy, hard, and of a reddish-brown color. (See *A. J. P.*, 1879, p. 152; also Penzoldt, *loc. cit.*; *P. J. Tr.*, xii.) Quebracho colorado has been used as a substitute for the true quebracho, but is essentially different from it, and probably is a simple astringent and gastro-intestinal stimulant, although Dr. Penzoldt claims that it is similar in its action, but much weaker than quebracho blanco. Perkin and Gunnel have determined the yellow coloring matter of the wood of quebracho colorado to be identical with fisetin, $C_{15}H_{10}O_6$, the coloring matter of young fustic (*Rhus cotinus*). It occurs in glistening yellow needles, dyeing similarly to quercetin, and yields compounds with mineral acids. Its benzoyl and acetyl derivatives have also been prepared. Fused with alkalies it yields protocatechuic acid and probably resorcinol. Ellagic and gallic acids have also been obtained from the wood, these being probably formed during the isolation of the fisetin. (*A. J. P.*, Nov. 1896, 626.)

aspidospermatine, $C_{22}H_{28}N_2O_2$, and isomeric with it *aspidosamine*, $C_{22}H_{28}N_2O_2$, *quebrachine*, $C_{21}H_{26}N_2O_2$, and isomeric with this *hypoquebrachine*, $C_{21}H_{26}N_2O_2$, and *quebrachamine*. (*Ber. der Chem. Ges.*, xiii. 2308.) *Aspidospermine* fuses at 205°–206° C., is soluble in about 6000 parts of water at 15° C. (59° F.), and the solution has a decidedly bitter taste, soluble in about 48 parts of absolute alcohol, in 106 parts of ether, insoluble in glycerin; it dissolves readily in fats and fixed oils, cod-liver oil dissolving a larger proportion than it does of quinine. Its *sulphate* and *hydrochlorate* are very soluble. The citrate is crystallizable, and very soluble. The yield of aspidospermine is very small, 0·33 per cent. of the bark. *Aspidospermatine* is crystalline, and fuses at 162° C.; *aspidosamine* is amorphous, and fuses at 100° C.; *quebrachine* in colorless crystals fuses at 214°–216° C.; *hypoquebrachine* is a yellowish mass resembling albumen, and fuses at 80° C.; *quebrachamine* forms colorless silky needles, only slightly soluble in alcohol, ether, chloroform, and benzin, and fuses at 142° C. Two new varieties of sugars have also been extracted by Tanret, *quebrachite* and *lævogyre inosite*. Tannin and starch have also been found in the bark.

Medical Properties and Uses. Quebracho bark is said to be employed as an antiperiodic in Chili, but in Europe and America it has been used solely as a remedy in *cardiac* and *asthmatic dyspnœa*. (*Die Wirkungen Quebrachodrogin*, Dr. F. Penzoldt, Erlangen, 1881.) In the lower animals large doses of the bark produce motor palsy, with dyspnœa, and finally death, apparently from asphyxia. The breathing early becomes slower in rate, but deeper; the blood-pressure is not much affected until late. Our knowledge of the action of the alkaloids of quebracho is very imperfect, and we give a synopsis of the important researches in a footnote.* A notable phenomenon observed with all the alkaloids was that, although death apparently took place from asphyxia, the venous blood was red or reddish. It would seem to be proved that the active principles of quebracho have a very notable influence upon the respiratory centres; and the curious coloration of the blood seen after death has given rise to the belief that the alkaloid directly affects the blood in its relations to oxygen. Indeed, Dr. F. Penzoldt (*loc. cit.*) believes that the relief of dyspnœa obtained clinically by the use of the drug is caused by its increasing the power of the blood to take oxygen, and the dyspnœa caused by poisonous doses he attributes to its preventing the blood yielding the oxygen to the tissues, but he does not prove his theory. There would seem to be a physiological basis for the results obtained by various clinicians, who have found that quebracho is a valuable remedy when the respiration is embarrassed by *emphysema*, *bronchitis*, *chronic pneumonia*, and other complaints mechanically influencing pulmonary functions. Even in *uræmic dyspnœa* the remedy has been found useful. Aspidospermine of commerce is a more or less impure mixture of all alkaloids of the bark, and hence may be considered to represent its activity. The dose of the commercial aspidospermine is from a quarter to half a grain (0·016 to 0·03 Gm.). The fluid extract may be given in doses of from a quarter to one fluidrachm (1 to 4 C.c.); the solid extract is said to be ten times the strength of the crude bark, and may be given in doses of from one to three grains (0·065 to 0·194 Gm.).

* Several experimenters have studied more or less completely the physiological action of the alkaloids of quebracho blanco. Harnack and Hoffmann (*Zeit. für Klin. Med.*, 1884, vol. viii.) find that *aspidospermatine* causes in the frog respiratory paralysis, with palsy of all the striated muscular fibre of the body, including the heart-muscle. Upon mammals it acts very feebly, its most marked influence being upon the respiration. *Quebrachine* acted upon the frog precisely as did aspidospermatine. Its influence upon the mammal was at least twenty times as great as that of aspidospermatine, comparatively small doses producing death by respiratory paralysis. *Quebrachamine* acted very much as did aspidospermatine upon the breathing and upon the muscular fibre. *Aspidosamine* acted upon the breathing and upon the muscular fibre like aspidospermatine, but also paralyzed the motor nerve-endings. Its influence upon mammals was quite feeble. According to this research, the combined alkaloids have especial influence upon the respiration and the respiratory centres, and at the same time affect the muscular fibres directly and the peripheral nerve-endings. Schiffer (*Archiv f. Physiol.*, 1883, p. 249) has found that the extract of a commercial quebracho blanco produces in the rabbit general muscular weakness, followed by paralysis with greatly diminished reflexes and an appearance of the deepest narcosis, with increased frequency of breathing, unaltered cardiac activity, and unchanged pupils. After very large doses death occurs in a very short time, preceded by convulsions. The motor nerve-trunks were found even during life almost devoid of functional activity. The exact nature of the bark used for the making of the extract is not stated. Eloy and Huchard (*Archives de Phys. et Path.*, April 1, 1886) found that the extract of quebracho blanco has some effect on sensibility after the taking out of the quebrachine, hypoquebrachine, aspidospermine, and aspidospermatine, but that these alkaloids themselves have no effect on general sensibility. The four alkaloids named produced paralysis, with, if in excessive doses, tonic convulsions, and all of them had the power of reducing the temperature, quebrachine being in this respect the most active. Aspidospermine increased the amplitude of the respiratory movements to a very marked degree, but in overdose produced irregularity and failure of respiration. The three other alkaloids had much less effect upon respiration.

ATROPINA. U. S., Br. Atropine.

$C_{17}H_{23}NO_3$; 288·38. (ĂT-RŌ-PĪ′NĄ.) $C_{17}H_{23}NO_3$; 289.

"An alkaloid obtained from Belladonna. As it occurs in commerce, it is always accompanied by a small proportion of hyoscyamine extracted along with it, from which it cannot be readily separated." *U. S.* "An alkaloid, $C_{17}H_{23}NO_3$, obtained from Belladonna Leaves or Root." *Br.*

Atropia; Atropinum, *P. G.;* Atropine, *Fr.;* Atropin, *G.*

Because atropine cannot profitably be manufactured on a small scale, both Pharmacopœias have omitted the processes of preparation, and furnish only qualitative tests. For the U. S. process of 1870, see foot-note.* For discussion, see U. S. D., 14th edition.

Properties and Tests. Atropine is in "white, acicular crystals, or a more or less amorphous, white powder, without odor, having a bitter, acrid taste, and gradually assuming a yellowish tint on exposure to air. Soluble, at 15° C. (59° F.), in 130 parts of water, 3 parts of alcohol, 16 parts of ether, 4 parts of chloroform, and about 50 parts of glycerin. At about 115° C. (239° F.) it melts, forming a colorless liquid; at about 140° C. (284° F.) it begins to give off white, acrid fumes, and, when ignited, it is consumed without leaving a residue. It has a markedly alkaline reaction; its saturated aqueous solution acquires a pink color upon the addition of a drop of phenolphtalein test-solution. If a small quantity of atropine, or of one of its salts, be heated with a few C.c. of concentrated sulphuric acid, a peculiar odor, recalling that of a mixture of rose, orange-flower, and melilot, will become noticeable. On now gradually adding minute fragments of potassium dichromate, the odor will change to that of oil of bitter almond, the rose odor disappearing as more dichromate is added. Atropine and its salts are decomposed by prolonged contact with sodium or potassium hydrate, and if heated with either of them, evolve ammonia. On dissolving a small quantity (about 0·1 Gm.) of atropine in 2 C.c. of alcohol, and adding an equal volume of mercuric chloride test-solution, a yellow precipitate, which soon turns red, is produced. On adding concentrated sulphuric acid to atropine, no color should be produced (absence of *readily carbonizable, organic impurities*), nor should any color be developed by the subsequent addition of nitric acid (absence of and difference from *morphine*). The aqueous solution of atropine, or of any of its salts, is not precipitated by platinic chloride test-solution (difference from *most other alkaloids*). With gold chloride test-solution it gives a precipitate which, when recrystallized from boiling water acidulated with hydrochloric acid, is deposited, on cooling, in minute crystals forming a yellow, lustreless powder on drying (difference from, and absence of more than a small proportion of, *hyoscyamine*)." *U. S.* The British Pharmacopœia states that atropine is "soluble in 300 parts of *water*, readily soluble in *alcohol* (90 per cent.), in *chloroform*, and in *ether*. Melting point 239° to 240° F. (115° to 115·5° C.). When moistened with *fuming nitric acid* and evaporated to dryness on a water-bath, the residue gives with freshly prepared alcoholic solution of *potassium hydroxide* a fugitive reddish-violet coloration. It leaves no ash when burned with free access of air (absence of mineral matter)." For further information, see *Belladonna;* † also *A. J. P.*, 1884, 206.

It is inflammable, giving off an odor like that of benzoic acid, and, when burned in the open air, leaving no residue. By distilling it with potassium bichromate and sulphuric acid, Dr. E. Pfeiffer succeeded in obtaining crystals of benzoic acid and propylamine. (*A. J. P.*, 1864, 226.) Dr. Kraut, by heating it with baryta water, succeeded in obtaining a peculiar acid and

* "Take of Belladonna Root, in fine powder, *forty-eight troyounces;* Purified Chloroform *four troyounces and a half;* Diluted Sulphuric Acid, Solution of Potassa, Alcohol, Water, each, *a sufficient quantity.* Mix the powder with a pint of Alcohol, and having introduced the mixture into a cylindrical percolator, pour alcohol gradually upon it until sixteen pints have passed. From the liquid thus obtained distil off twelve pints of Alcohol. To the residue add sufficient Diluted Sulphuric Acid to give it an acid reaction, and, having evaporated the liquid to half a pint, add an equal bulk of Water, and filter through paper. To the filtered liquid add, first a troyounce and a half of the Chloroform, and then Solution of Potassa in slight excess, and shake the whole together at intervals for half an hour. When the heavier liquid has subsided, separate it, and, having added a troyounce and a half of the Chloroform to the lighter liquid, again shake them together, and separate the heavier from the lighter liquid as before. Add to this lighter liquid the remainder of the Chloroform, and, after agitation, separate the heavier liquid for the third time. Mix the heavier liquids in a capsule, and set the mixture aside until, by spontaneous evaporation, the Atropia is left dry." *U. S.* 1870.

† For the behavior of atropine under the influence of an electric current, see *P. J. Tr.*, 1870, i. 244.

It is stated by H. Bullot that if to an aqueous solution of atropine acidulated with sulphuric acid an aqueous solution of picric acid be added, a precipitate will not form with good English atropine; with that obtained by the method of Simon, there will be a very slight precipitate; with the German alkaloid, an abundant yellow precipitate.

peculiar base, the former of which he calls *tropic acid*, $C_9H_{10}O_3$, melting at 117° C., and oxidizable by dilute potassium permanganate to bitter almond oil and benzoic acid, and the latter *tropine*,* $C_8H_{15}NO$, melting at 62° C. (*Ibid.*, 232.) Ladenburg (*Ber. Chem. Ges.*, 12, 942, and 13, 104) has succeeded in effecting the synthesis of atropine from these two constituents, which, when heated over a water-bath in the presence of dilute hydrochloric acid, unite to form the alkaloid. Ladenburg has also succeeded in forming a series of compound esters of tropine with other organic acids to which the general name of *tropeines* has been given. Some of these have pronounced toxic effects, and one (homatropine) has found use as a valuable substitute for atropine. The list of artificial tropeines thus prepared includes:

Benzoyl-tropeine, $C_{15}H_{19}NO_2 + 2H_2O$.

Salicyl-tropeine, $C_{15}H_{19}NO_3$. Strong base, weak poisonous action.

m-oxybenzoyl-tropeine, $C_{15}H_{19}NO_3$.

p-oxybenzoyl-tropeine, $C_{15}H_{19}NO_3 + 2H_2O$.

Phenyl-acet-tropeine, $C_{16}H_{21}NO_2 + H_2O$.

Oxytoluyl-tropeine (homatropine), $C_{16}H_{21}NO_3$. Has mydriatic action; less poisonous than atropine.

Cinnamyl-tropeine, $C_{17}H_{21}NO_2$. Strong base, but without mydriatic action.

Atropyl-tropeine, $C_{17}H_{21}NO_2$.

Atrolactyl-tropeine, $C_{17}H_{23}NO_3$. Has similar action to atropine.

Phthalyl tropeine, $C_{24}H_{32}N_2O_4$.

Hinterberger states that an alcoholic solution of atropine, when cyanogen is passed through it, assumes a blood-red color, and, on spontaneous evaporation, deposits a red, syrupy liquid insoluble in water. (Gmelin.) The detection of atropine in small quantity is a matter of great difficulty; the best test is the physiological, which consists in placing the suspected liquid in the eye of a cat, or other animal, when, if the alkaloid be present, dilatation of the pupil will occur. According to Brunner, the best chemical test is the aromatic smell which is produced by adding the alkaloid and a little water to a hot mixture of sulphuric acid and potassium bichromate or ammonium molybdate. (*P. J. Tr.*, iv. 385.) Fabris believes that strychnine in the presence of atropine interferes with the toxicological identification of the latter by chemical tests, but a physiological test reveals the presence of both alkaloids. (*Bul. de la Société Royale de Pharm.*, 1894.) Prof. Wormley made comparative examinations of various tests for atropine, hyoscyamine, and hyoscine. (See *A. J. P.*, 1894, 513.)

Medical Properties and Uses. The local and general effects of atropine on the system are precisely those of belladonna. It is, however, more speedy in its operation, probably in consequence of its easier absorption. Thus, the poisonous action of belladonna is seldom experienced in less than half an hour, while that of atropine shows itself violently in fifteen or twenty minutes. The most prominent effects from small remedial doses are dryness and stricture of the throat, and slight uneasiness of the head, with confusion or giddiness; from somewhat larger doses, dilatation of the pupil, some dimness of vision, frontal headache, hurried respiration, slight delirium, flushed face, and sometimes a scarlet rash. After poisonous doses the above symptoms occur in a more aggravated form. Two distinct stages of the poisoning can usually be noted. At first there is great dimness or total temporary loss of vision, excessive dilatation of the pupil, headache, delirium, which is always talkative and may be violent, an enormous increase in the frequency of the pulse, which is also small and hard, an elevation of the bodily temperature, and decided increase of the rate of respiration. Subsequently the second stage develops, and paralytic symptoms set in: the delirium gives way to stupor, restlessness to paralytic weakness, the pulse becomes very feeble, the surface cold, the respirations grow more and more shallow, and death from failure of both respiration and circulation occurs.

* The physiological action of *tropine hydrochlorate* has been partially investigated by Dr. H. G. Beyer. (*Med. News*, Aug. 27, 1887.) He concludes that it gives rise to vaso-motor constriction by exciting the vaso-motor constrictors, and that it sometimes causes vaso-motor dilatation by exciting vaso-motor dilator nervous elements. As the result of an elaborate series of experiments, Gottlieb (*Archiv f. Exp. Path. u. Pharm.*, Bd. xxxii., 1896) has reached the conclusion. First, that some of the tropeines not only differ quantitatively in their action from atropine, but are wanting in the peripheral action of that alkaloid; such are *Acetyltropine* and *Succinyltropine*. Second, as far as our knowledge goes, there seems to be a complete parallelism in the action of the tropines and the tropeines on the ends of the vagi in the heart and the pupils. (This influence can be seen in certain Fettsäure-Estern, and may be wanting in some aromatic tropeines.) Third, the tropines and the less poisonous tropeines are cardiac stimulants, an influence not shared by atropine. [This latter assertion is probably incorrect.] The influence upon the heart probably consists in an increasing of the excitability of the motor heart ganglia.

In some instances violent convulsions have occurred; nausea and vomiting, and even diarrhœa, are occasionally produced. The atropine is eliminated by the kidneys, and may produce increased diuresis, but usually there is, in cases of poisoning, retention of urine from vesical paralysis. The increase of the heart's action by atropine is chiefly due to its paralyzing the peripheral vagi, the inhibitory nerves of the heart; the final cardiac failure which takes place when poisonous doses have been taken is apparently the result of a direct depressant action on the heart-muscle. Upon the vaso-motor centres atropine in a moderate dose acts as a stimulant, thereby causing a great rise of the arterial pressure. After poisonous doses the primary vaso-motor spasm is followed by dilatation of the vessels and great fall of the arterial pressure. Paralysis of the motor nerves is one of the most marked effects of the poison; upon the afferent nerves the poison seems to have but little influence. On all non-striated muscle atropine exerts a very powerful influence, and it is probable, although not certain, that whilst in poisonous amount it lessens and finally paralyzes intestinal movements by a direct action upon the muscular coats, in small doses it increases peristalsis by paralyzing the inhibitory nerves which control this intestinal function. The action of the drug upon the respiratory centres is a very important one, atropine being in moderate doses one of the most powerful persistent stimulants to the respiratory centre known. The asphyxia of belladonna poisoning is certainly in large measure due to the paralysis of the nerve-trunks which the poison produces, although it is also probable that the first period of excitation of the respiratory centres is followed by one of depression.

Atropine chiefly depends for its therapeutic powers upon—1st, its sedative action upon the peripheral nerves; 2d, its stimulant action on the respiratory centres; 3d, its influence upon the heart and vaso-motor centres. By virtue of its first-mentioned power it is useful in *spasmodic diseases*, such as *whooping-cough*, *dysmenorrhœa*, *local spasm*, etc. As the action is upon the nerve-trunks, the remedy is much more effective when it can be applied locally, as by atomization in *whooping-cough* and *asthma*, or by hypodermic injection in *wry neck*. As atropine has some influence upon the afferent nerve, it has some power of relieving *pain;* but for this action to be marked, direct application is necessary. On account of its influence upon respiration, it is invaluable in *narcotic poisonings* and other bodily conditions with failure of the function. In *shock* and other similar states in which vaso-motor paralysis is an important part of the morbid condition, it is a very useful stimulant. On account of the paralyzing influence which it has upon the inhibitory intestinal nerves, atropine may be used as an adjuvant to more decided laxatives.

On the glandular system atropine exerts a decided influence; its effect upon the salivary and perspiratory glands being at present best understood. The remarkable action which it has in checking the functional activity of these glands is probably exerted through the nervous system, for in Keuchel's experiments it was distinctly proved that the chorda tympani nerve, excitation of which normally provokes salivation in atropine poisoning, is paralyzed. In a case recorded by Dr. James Andrew two-thirds of a grain of atropine occasioned the most alarming symptoms, which continued for several days (*Ed. Month. Journ. of Med. Sci.*, xiv. 34); and a lady under the care of M. Roux, of Brignolles, took somewhat more than a grain, with the same alarming symptoms (*Ann. de Thérap.*, 1861, p. 14); though in both cases recovery took place under treatment. In a child three years old less than half a grain was followed by similar dangerous symptoms and the same favorable result. (*Med. Times and Gaz.*, Dec. 1850, p. 601.) A solution of atropine dropped into the eye produces dilatation of the pupil after ten or fifteen minutes, without causing congestion or inflammation; and the dilatation will usually continue for three or four days. It is said that the dilatation is sometimes followed by contraction of the pupil, especially when the dose is large. The alkaloid also produces its characteristic constitutional effects when applied to the skin denuded of the epidermis, or to a mucous membrane, as of the rectum, vagina, etc., and especially when injected into the subcutaneous areolar tissue. The remedies for its poisonous operation are the same as those for belladonna; the most prominent being evacuation of the stomach, cold applications to the head, the preparations of opium internally, and stimulants when the strength is failing. As the value of atropine in opium poisoning, which seems unquestionable, is due to its influence on the respiratory centres, it is far from certain that opium is of at all proportionate advantage in poisoning by belladonna, etc. The official compound solution of iodine has been given as a chemical antidote to atropine, and with asserted advantage. It acts by forming an insoluble compound with the alkaloid. (See *Belladonna.*)

Atropine may be administered internally for all the purposes for which belladonna is given; and it is very largely used as a local remedy, for application to the eye, or to the surface of

the body, or for subcutaneous injection; and for these purposes it has the advantage over the ordinary preparations of belladonna of greater precision of dose, quickness of action, and neatness and cleanness. In *ptyalism* and in *colliquative sweats* the most prompt effects can be obtained from the hypodermic use of atropine. The hypodermic dose of atropine may be set down as the one-hundredth of a grain, the dose by the mouth as the one-seventy-fifth of a grain, although in serious cases these amounts may be much exceeded. Thus, in some cases of *opium poisoning* one-twentieth of a grain (0·003 Gm.) may be exhibited at once. On the other hand, in susceptible persons, one-hundredth of a grain (0·0006 Gm.) will produce decided dryness of the throat, and one-fiftieth of a grain (0·0012 Gm.) is alleged to have caused toxic symptoms. As the atropine itself is insoluble, the sulphate should always be preferred. For application to the sound skin, the form of ointment is most convenient. This may be made by rubbing a grain of the alkaloid first with four minims of alcohol, and then with a drachm of lard. Glycerin and olein also have been recommended as vehicles of atropine for external use, and may be incorporated with it in the same proportion.

When solution of atropine sulphate is used for *dilating the pupil*, it may be either dropped into the eye within the lower lid, or introduced on small slips of paper previously saturated with the solution and dried, or, what is still more convenient, by means of minute circular disks of gelatin, made by mixing the solution with gelatin and evaporating so as to procure a thin film, which is to be cut into circular pieces. These have the advantage over paper that they do not require to be subsequently removed from the eye.

The external use of atropine is not without danger, unless great caution be observed. A case is on record in which an ointment composed of three grains of the sulphate and two drachms of lard, applied upon a vesicated surface on the neck, produced in a few minutes the most violent symptoms of belladonna poisoning, ending in death in two hours. (*Ann. de Thérap.*, 1867, p. 9.) The solution of atropine or its salts* is very apt to have developed in it a fungous growth with consequent decomposition of the alkaloid.

ATROPINÆ SULPHAS. U. S., Br. Atropine Sulphate.

$(C_{17}H_{23}NO_3)_2, H_2SO_4$; 674·58. (ĂT-RŌ-PĪ'NÆ SŬL'FHĂS.) $(C_{17}H_{23}NO_3)_2, H_2SO_4$: 676.

"Atropine Sulphate, $(C_{17}H_{23}NO_3)_2H_2SO_4$, may be obtained by neutralizing Atropine with Diluted Sulphuric Acid." *Br.*

Sulphate of Atropia; Atropinum Sulfuricum, *P. G.;* Sulfate d'Atropine, *Fr.;* Schwefelsaures Atropin, *G.*

Neither the U. S. nor Br. Pharmacopœias give a process for preparing this salt. The official formula of 1870 is essentially the process of M. Ch. Maitre.† Atropine being soluble in ether, while its sulphate is insoluble in that fluid, a convenient method is afforded for preparing the sulphate with little evaporation. By adding the mixed acid and alcohol to the ethereal solution, the sulphate is formed, and, being insoluble in the ether, is deposited; while the little left dissolved in the alcohol is obtained by spontaneous evaporation. The quantity of acid added is intended to be just sufficient to saturate the alkaloid; but if the saturation should not be exact, it would be easy to render it so by the addition of a little more alkaloid or a little more acid, as required.

From the great facility with which atropine undergoes change, much caution is necessary in preparing its salts, and the process was arranged in reference to this caution. Upon the addition of the mixed acid and alcohol to the ethereal solution, the liquid becomes milky, and deposits on the sides of the vessel a copious precipitate of a viscid appearance, which soon dries upon the decantation of the ether and the placing of the vessel in a drying-room. To succeed

* *Atropine Salicylate.* This salt is alleged to have advantages over the sulphate, mainly because of its more rapid and efficient action, provided it be pure and perfectly neutral. It may be prepared by Frederici's process, which is to dissolve 23 parts of atropine in pure alcohol by a gentle heat, and to add enough salicylic acid (about 18 parts) to render the solution neutral, which is determined by the use of litmus paper. The solution is carefully evaporated, and finally dried in a drying-oven. It is deliquescent, and should be kept in securely-stopped vials. The dose is the same as that of the sulphate.

Atropinum Santonicum, a compound of atropine and santonic acid, is described by Herr Bombelon (*Pharm. Zeitung*, April, 1886) as an amorphous non-hygroscopic powder, readily soluble in water, which presents advantages over all other atropine salts in being non-irritating, and also in affording a solution which is stable if kept in yellow glass bottles to avoid the formation of photo-santonic acid. One drop of a solution of 0·01 Gm. in 20 Gm. of water is sufficient to dilate the pupil, the dilatation disappearing in from twelve to twenty-four hours.

† "Take of Atropia *sixty grains;* Stronger Ether *four fluidounces and a half;* Sulphuric Acid *six grains;* Stronger Alcohol *a fluidrachm.* Dissolve the Atropia in the Ether; then mix the Acid and Alcohol, and add the mixture, drop by drop, to the ethereal solution until the Atropia is saturated. Allow the liquid to stand until the precipitate formed is deposited. Then decant the ether, and expose the residue to spontaneous evaporation until the salt is dry." *U. S.* 1870.

with this process it is necessary that the liquids employed should be carefully freed from water, the sulphuric acid being monohydrated, and that the temperature should be kept as low as possible. There should be no excess of acid; and, if such an excess should be found upon applying the test of litmus paper, the solution should be neutralized by a portion of reserved solution of atropine. (*A. J. P.*, xxviii. 361; from *Répert. de Pharm.*) In the British process the same object of avoiding decomposition by heat is attained by the low temperature at which the evaporation is effected.

Properties. A white, indistinctly crystalline powder, permanent in the air, odorless, having a very bitter, nauseating taste, and a neutral reaction. "Soluble, at 15° C. (59° F.), in 0·4 part of water, 6·2 parts of alcohol, 2270 parts of ether, or 694 parts of chloroform. At 187° C. (309° F.) the salt melts, forming a brownish-yellow liquid. When ignited, it chars, emits acrid vapors, and is completely consumed. The salt is neutral to litmus paper. On adding sodium carbonate test-solution to a concentrated aqueous solution of the salt, a white precipitate is obtained which should respond to the reactions and tests given under atropine (see *Atropina*). The aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid." *U. S.* "Soluble in 10 parts of *alcohol* (90 per cent.) and in 1 part of cold *water*, forming solutions which are neutral to *litmus*, and which, even when considerably diluted, if applied to the eye will dilate the pupil. It is insoluble in *ether* and in *chloroform*. It yields the characteristic reactions with the tests for sulphates. Melting point 361·4° F. (183° C.)." *Br.*

If it be required to procure the sulphate in the form of crystals, which may sometimes be desirable, to avoid adulteration, the process of M. Laneau may be employed. A solution of crystallized atropine in absolute alcohol, in the proportion of 2·89 parts of the former to 4 parts of the latter by weight, having been made with the assistance of a gentle heat, 0·4 part of sulphuric acid of the sp. gr. 1·85, diluted with 3 parts of absolute alcohol, is to be gradually added, and stirred with a glass rod, until saturation, as shown by test-paper, is effected. The solution is then allowed to evaporate spontaneously, and the thinner the stratum the sooner will the process be completed. The crystals are in colorless needles more or less interlaced. (See *A. J. P.*, 1863, p. 315.)

The effects of the salt on the system are precisely the same as those of atropine, and it may be used in the same dose. Its great advantage over the alkaloid is its solubility in water. A one-per-cent. solution is said to be instantaneously efficacious in *toothache*, applied to the denuded dental pulp; and also to produce complete insensibility of the dental nerves, in cases in which an artificial tooth is inserted in a living root. (*Ann. de Thérap.*, 1861, p. 19.)

AURANTII AMARI CORTEX. U. S. (Br.) Bitter Orange Peel.

The U. S. Pharmacopœia includes two kinds of orange peel, bitter and sweet, the former obtained from Citrus vulgaris, the latter from Citrus Aurantium; on the other hand, the British Pharmacopœia recognizes bitter orange peel in two forms, the fresh and the dried, under the respective names of Aurantii Cortex Recens, fresh bitter orange peel, and Aurantii Cortex Siccatus, dried bitter orange peel; but the orange peel which is called sweet by the U. S. Pharmacopœia—*i.e.*, Citrus Aurantium—is termed bitter orange peel by the British authority.

This very interesting genus is composed of small evergreen trees, with ovate or oval-lanceolate and shining leaves, odoriferous flowers, and fruits which usually combine beauty of color with a fragrant odor and grateful taste. They are all natives of warm climates. Though the species are not numerous, great diversity exists in the character of the fruit; and many varieties, founded upon this circumstance, are noticed by writers. In the splendid work on the

natural history of the *Citrus* by Risso and Poiteau, 169 varieties are described under the eight following heads: 1, sweet oranges, 2, bitter and sour oranges, 3, bergamots, 4, limes, 5, shaddocks, 6, lumes, 7, lemons, and 8, citrons. Of these it is difficult to decide which have just claims to the rank of distinct species and which must be considered merely as varieties. Those employed in medicine may be arranged in two sets, of which the orange, *C. aurantium*, and the lemon, *C. medica*, are respectively the types; the former characterized by a winged, the latter by a naked or nearly naked petiole. The form and character of the fruit, though not entirely constant, serve as the basis of subdivisions. *C. decumana*, which yields the *shaddock*, agrees with *C. aurantium* in the form of its petiole.

Citrus aurantium. Willd. *Sp. Plant.* iii. 1427; *B. & T.* 51. The orange-tree grows to the height of about fifteen feet. Its stem is rounded, much branched, and covered with a smooth, shining, greenish-brown bark. In the wild state, and before inoculation, it is often furnished with axillary spines. The leaves are ovate, pointed, entire, smooth, and of a shining pale green color. When held between the eye and the light, they exhibit numerous small transparent vesicles, filled with volatile oil; and, when rubbed between the fingers, are highly fragrant. Their footstalks are about an inch long, and have wings or lateral appendages. The flowers, which have a delightful odor, are large, white, and attached by short peduncles, singly, or in clusters, to the smallest branches. The calyx is saucer-shaped, with pointed teeth. The petals are oblong, concave, white, and beset with numerous small glands. The filaments are united at their base in three or more distinct portions, and support yellow anthers. The germen is roundish, and bears a cylindrical style, terminated by a globular stigma. The fruit is a spherical berry, often somewhat flattened at its base and apex, rough, of a yellow or orange color, and divided internally into nine vertical cells, each containing from two to four seeds, surrounded by a pulpy matter. The rind of the fruit consists of a thin exterior layer, abounding in vesicles filled with a fragrant volatile oil, and of an interior one, which is thick, white, fungous, insipid, and inodorous. There are two varieties of *C. aurantium*, considered by some as distinct species. They differ chiefly in the fruit, which in one is sweet, in the other is sour and bitterish and has a darker and rougher rind. The first retains the original title, the second (the Seville orange) is called *Citrus vulgaris* by De Candolle, and *C. bigaradia* by Risso.*

This beautiful evergreen, in which the fruit is mingled, in every stage of its growth, with the blossoms and foliage, has been applied to numerous purposes of utility and ornament. A native of China and India, it was introduced into Europe at a very early period, was transplanted to America soon after its first settlement, and is now found in every civilized country where the climate is favorable. The fruit is brought to us chiefly from Florida, the south of Europe, and the West Indies. The Florida and Havana oranges are the sweetest.

Various parts of the plant are used in medicine. The leaves, which are bitter and aromatic, are employed in some places in the form of infusion as a gently stimulant diaphoretic. They yield by distillation with water a volatile oil, which is said to be often mixed by the distillers with the oils obtained from the flowers and unripe fruit. In regard to polarized light it has a rotatory power to the left, which is considerably weakened by the prolonged action of heat. (Chautard, *Journ. de Pharm.*, 3e sér., xliv. 28.) The fresh flowers may be kept for some time by mixing them well with half their weight of sodium chloride, pressing the mixture in a suitable jar, and keeping it well closed in a cool place. They were formerly recognized by the U. S. P. under the name of *Aurantii Flores*, and were officially described as "about half an inch (12 mm.) long; calyx small, cup-shaped, five-toothed; petals five, oblong, obtuse, rather fleshy, white and glandular-punctate; stamens numerous, in about three sets; ovary globular, upon a small disk, with a cylindrical style, and a globular stigma; odor very fragrant; taste aromatic and somewhat bitter." *U. S.* 1880. The dried flowers are used on the continent of Europe as a gentle nervous stimulant, in the form of infusion, two drachms to the pint of boiling water, taken in the dose of a teacupful. The flowers should be dried in the shade, at a temperature between 24° C. (75° F.) and 35° C. (95° F.).

An oil is obtained also from the flowers by distillation, which is called *neroli* in France, and is much used in perfumery, and in the composition of *liqueurs*. (See *Oleum Aurantii Florum.*)

* A variety of the orange, called the *Mandarin Orange* (*Citrus bigaradia sinensis* or *C. bigaradia myrtifolia*), which is probably a native of China, but cultivated in Sicily, the south of Italy, and Florida, bears a fruit much smaller than the common orange, round, but flattened above and below, with a smooth, thin, delicate rind, and a very sweet delicious pulp. A volatile oil is obtained from the rind by expression, of a yellow color, a very bland agreeable odor, different from that of the orange or lemon, and a not unpleasant taste, like that of the rind. When freed from coloring matter by distillation, it was found by M. S. de Luca to be a pure hydrocarbon, with the formula $C_{10}H_{16}$. (*Journ. de Pharm.*, 3e sér., xxxiii. 52.)

It is an ingredient of the famous Cologne water. That obtained from the flowers of the Seville or bitter orange (*C. vulgaris*) is deemed the sweetest. It was introduced into the Edinburgh Pharmacopœia, with the title of *Aurantii Oleum*, to serve for the preparation of orange-flower water. Soubeiran considers this oil rather as a product of the distillation than as pre-existing in the flowers. The fact may thus be explained that orange-flower water made by dissolving even the finest neroli in water has not the precise odor of that procured by distillation from the flowers. Pure neroli has a rotating power to the right, in this respect differing from the oil of the leaves. (*Chautard.*)

The fruit is applied to several purposes. Small unripe oranges, about the size of a cherry or less, previously dried, and rendered smooth by a turning-lathe, are sometimes employed to maintain the discharge from issues. They are preferred to peas on account of their agreeable odor, and by some are thought to swell less with the moisture; but this is denied by others, and it is asserted that they require to be renewed at the end of twenty-four hours. These fruits are sometimes found in commerce under the name of *orange berries*. They are of a grayish or greenish brown color, fragrant odor, and bitter taste, and are said to be used for flavoring cordials. A volatile oil is obtained from them by distillation, known to the French by the name of *essence de petit grain*, and employed for similar purposes with that of the flowers. The oil, however, which now goes by this name is said to be distilled from the leaves, and those of the bitter orange yield the best. The oils from the unripe and the ripe fruit have a rotating power to the right, the latter much greater than the former; and this property might serve to distinguish them from the oil of the leaves. Several of the oils from the Aurantiaceæ deposit a crystalline substance, differing from camphor. (*Chautard.*) The juice of the Seville orange is sour and bitterish, and forms with water a refreshing and grateful drink in febrile diseases. It is employed in the same manner as lemon-juice, which it resembles in containing citric acid, though in much smaller proportion. The sweet orange is more pleasant to the taste, and is extensively used as a light refrigerant article of diet in inflammatory diseases, care being taken to reject the membranous portion. The best mode of separating the outer rind, when its desiccation and preservation are desired, is to pare it from the orange in narrow strips with a sharp knife, as we pare an apple. When the object is to use the fresh rind for certain pharmaceutical purposes, as for the preparation of the *confection of orange peel*, it is best separated by a grater. The dried peel sold in the shops is usually that of the Seville orange, and is brought chiefly from countries adjacent to the Mediterranean.

Properties. Orange peel has a grateful aromatic odor, and a warm bitter taste, which depend upon the volatile oil contained in its vesicles. "In narrow, thin bands, or in quarters; epidermis of a dark brownish-green color, glandular, and with very little of the spongy, white, inner layer adhering to it; it has a fragrant odor, and an aromatic, bitter taste." *U. S.* The Br. Pharmacopœia requires that the outer surface both of the fresh and of the dried bitter orange peel shall be of a deep orange-red color, and rough and glandular. As lemon peel is sometimes substituted for orange peel, a means of distinguishing between them has been devised by E. G. Clayton (*Analyst*, xix. 134), which is to touch small fragments of peel with a glass rod dipped in hydrochloric acid. Orange peel is colored a rich, dark green; the color of lemon peel is unaffected. The sweet peel is orange yellow and has a sweetish, fragrant odor, and an aromatic, slightly bitter taste. Both orange peels yield their sensible properties to water and alcohol. The bitter principle, *hesperidin*, $C_{22}H_{26}O_{12}$, was discovered by Lebreton in 1828, but its character as a glucoside was first established by Hilger and Hoffmann. (*Ber. d. Chem. Ges.*, 9, 26, 685.) Treated with dilute acids it yields *hesperetin*, $C_{16}H_{14}O_6$, and glucose. It is crystalline (fusing point 250°–251° C.), and may be prepared by Paterno and Briosi's process, as follows. The cut and bruised oranges are covered with diluted alcohol, potassa solution added in excess, the liquor filtered after two days, and impure hesperidin precipitated by hydrochloric acid; the precipitate is boiled with acetic acid for ten minutes, and, after cooling, filtered from the resinous mass left. The hesperidin gradually separates from the filtrate upon standing, in white fine needles. From 4000 oranges about 6 ounces av. of the principle were obtained. (*Ber. d. Chem. Ges.*, 1876, 250–252.) Tanret found in the rind of the bitter orange, 1, a crystalline acid, $C_{44}H_{28}O_{14}$; 2, a non-crystalline resinous body; 3, *hesperidin;* 4, *isohesperidin*, a crystalline glucoside isomeric with hesperidin; 5, *aurantianarin*, a new glucoside, to which the bitterness of the peel is due. (*P. J. Tr.*, 1886, 839.) Orange peel contains also albumen, gum, resin, a trace of fixed oil, volatile oil, and a principle resembling tannin in its action on salts of iron. The bitter principles are said to be much more abundant in the white spongy inner portion of the peel than in the outer yellowish layer. The volatile oil may be obtained

by expression from the fresh grated rind, or by distillation with water. It is imported into the United States in tinned copper cans. It has properties resembling those of the oil of lemons, but spoils more rapidly on exposure to the air, acquiring a terebinthinate odor. The perfumers use it in the preparation of Cologne water, and for other purposes; and it is also employed by the confectioners. According to Dr. Imbert-Gourbeyre, persons who are much exposed to the inhalation of the oil of bitter oranges are apt to be affected with cutaneous eruptions, and various nervous disorders, as headache, tinnitus aurium, oppression of the chest, gastralgia, want of sleep, and even muscular spasm. (*Pharm. Centralblatt*, Feb. 1854, 128.)

Medical Properties and Uses. Bitter orange peel is a mild tonic, carminative, and stomachic; the sweet is simply aromatic; but neither is much used alone. They are chiefly employed to communicate a pleasant flavor to other medicines, to correct their nauseating properties, and to assist their stimulant impression upon the stomach. They are a frequent and useful addition to bitter infusions and decoctions, such as those of gentian, quassia, columbo, and Peruvian bark. It is obviously improper to subject orange peel to long boiling, as the volatile oil is thus driven off. The dose in substance is from half a drachm to a drachm (1·95–3·9 Gm.). Violent colic, convulsions, and even death have been caused in children by eating large quantities of the rind. When orange peel is used simply for its agreeable flavor, the rind of the sweet orange is preferable; as a tonic, that of the Seville orange.

AURUM. Gold.

(ÂU'RŬM.)

The preparations of gold were introduced into medical practice in 1810 by Chrestein, of Montpellier. They have been especially recommended in various chronic diseases of the nervous system and skin, also in inveterate constitutional syphilis and allied disorders. The U. S. Pharmacopœia recognizes one preparation (see below). For a discussion of the various non-official preparations which have been used in medicine, see *Gold*, PART II.

AURI ET SODII CHLORIDUM. U. S. Gold and Sodium Chloride.

(ÂU'RĪ ĔT SŌ'DI-Ī ȻHLŌ'RI-DŬM.)

"A mixture of equal parts, by weight, of dry Gold Chloride [$AuCl_3 = 302{\cdot}81$] and Sodium Chloride [$NaCl = 58{\cdot}37$]. It should be kept in well-stoppered vials." *U. S.*

Gold and sodium chloride may be prepared by dissolving gold in nitrohydrochloric acid, evaporating the solution to dryness, weighing, and dissolving the dry mass in eight times its weight of distilled water. To this solution a weight of pure decrepitated common salt equalling that of the dry gold chloride is added, previously dissolved in four parts of water. The mixed solution is then evaporated to dryness, being in the mean time constantly stirred with a glass rod. A process for making this salt from gold coin without requiring the preliminary purification necessary in the above process may be found in *Proc. A. P. A.*, 1882, p. 311.

Properties. The salt is of a golden-yellow color, and, when crystallized, is in the form of long prismatic crystals, unalterable in the air. The Pharmacopœia describes it as "an orange-yellow powder, odorless, having a saline and metallic taste, and slightly deliquescent in damp air. The compound is very soluble in water, and at least one-half of it should be soluble in cold alcohol. When exposed to a red heat, it is decomposed, and metallic gold is separated. A fragment of the compound imparts a persistent, intensely-yellow color to a non-luminous flame. Its aqueous solution has a slightly acid reaction, and yields, with silver nitrate test-solution, a white precipitate insoluble in nitric acid. On bringing a glass rod, dipped into ammonia water, close to a portion of the compound, no white fumes should make their appearance (absence of *free acid*). If 0·5 Gm. of Gold and Sodium Chloride be dissolved in 50 C.c. of water, in a porcelain capsule, the solution acidulated with 5 C.c. of diluted sulphuric acid, and after the addition of 1 Gm. of pure oxalic acid, heated for about two hours, on a water-bath, a precipitate of metallic gold will be obtained, which, when washed, dried, and ignited, should weigh not less than 0·15 Gm. (corresponding to at least 30 per cent. of metallic gold). The filtrate from the precipitated gold should not be affected by hydrogen sulphide test-solution, nor, after being supersaturated with ammonia water, by ammonium sulphide test-solution (absence of *metallic impurities*)." *U. S.*

Medical Properties. The precise action of this salt upon the system is not known, but it is thought to affect the general nutrition, and to be therefore alterative. By many gynæcologists it is believed to have a specific direction to the genital organs, and it is used in *hysteria, ovarian irritation and neuralgia, chronic ovaritis*, and even *chronic uterine inflammation*. It

has also been commended in *syphilis*, *chronic rheumatism*, *diabetes mellitus*, and other chronic disorders affecting nutrition. The double salt of gold and sodium chloride has recently been very largely used in the treatment of the *alcoholic habit*. It is believed to be the basis of the notorious "*Keeley cure*," which, according to the best information obtainable, seemingly reliable, consists in chief part of the administration of ascending doses of the double chloride, with hypodermic injections in the interim (one every three hours) of very minute doses of atropine and strychnine. It would seem certain that no medication can suffice for moral reformation, but there is considerable evidence to show that the treatment just spoken of, by toning up the nervous system and bringing about a general increase of nutritive tone, may aid those who are determined upon reform. Dose, one-quarter to one-twelfth of a grain (0·015 to 0·005 Gm.).

BALSAMUM PERUVIANUM. U. S., Br. Balsam of Peru.

(BĂL'SĄ-MŬM PĘ-RŪ-VĮ-Ā'NŬM.)

"A balsam obtained from Toluifera Pereiræ (Royle), Baillon (nat. ord. Leguminosæ)." *U. S.*

"A balsam exuded from the trunk of Myroxylon Pereiræ, Klotzsch, after the bark has been beaten and scorched." *Br.*

Balsamum Peruvianum Nigrum, Balsamum Indicum; Baume des Indes, Baume de Pérou, *Fr.;* Peruvianischer Balsam, *G.;* Balsamo del Peru, *It.;* Balsamo negro, *Sp.*

Gen. Ch. Calyx subincurved, irregularly dentate. *Vexillum* broadly orbiculate; four inferior *petals* sub-equal, free, narrow. *Stamens* deciduous with the petals, free or at their extreme base very shortly connate. *Ovaries* long, stipitate, near the apex two ovulate. *Styles* short incurved, with a minute terminal stigma. *Legume* stipitate, compressed, indehiscent, with the apex indurated, and one-seeded. *Seed* one, subreniform, with a thin testa. *Cotyledons* plano-convex. *Radicle* very short, incurved. (Bentham and Hooker, *Genera Plantarum.*)

De Candolle and other botanists considered that the genera Myroxylon and Toluifera of Linnæus are not distinct from Myrospermum of Jacquin, but it is now generally recognized that the two Linnæan genera are, taken together, entitled to rank as a single genus. To this the title of Myroxylon has been generally applied by botanists following Bentham and Hooker, but Baillon (*Natural History of Plants*, vol. ii. 366) seems to be in accord with the generally accepted rules of botanical nomenclature in preferring the name Toluifera. In regard to the species now under consideration there has been much discussion, and although the plant is now well known botanically, botanists are not agreed as to its specific distinctness; Ruiz (*Flora Peruviana*), Carson (*A. J. P.*, 1860, p. 297), Baillon, and others believing it to be identical with the tree which yields balsam of Tolu. Flückiger and Hanbury (*Pharmacographia*, 2d ed., 205) give the following points of difference: in *M. pereiræ* the branches come off near the ground, the calyx is widely cup-shaped, and shallow, the racemes loose, 6 to 8 inches long, and the legume much narrowed at its base; whilst in *M. toluifera* the trunk does not branch for 30 or 40 feet, the calyx is rather tubular, the racemes dense and 3 to 4½ inches long, the legume scarcely narrowed at the base. Besides the official species, there are others of the genus which possess medical virtues, and have been more or less employed.* The pod of *M. frutescens* (Jacq.), growing in Trinidad, is popularly used in that island as a carminative, and externally, in the form of a tincture, as a lotion in rheumatic pains; and by incisions in the stem a small quantity of balsamic juice is obtained not distinguishable from balsam of Tolu. (*P. J. Tr.*, Sept. 1862, p. 108.) Another species is known in Paraguay under the name of *quino-quino*, the bark of which is used, in powder and decoction, as a remedy in wounds and ulcers, and from the trunk of which a juice is obtained which in its concrete state closely resembles dried balsam of Peru. (*Ibid.*, Oct. 1862, p. 183.)†

* For an account of the various imperfectly described species related to this plant, see 14th Ed. U. S. D.

† A product of *T. peruiferum*, sometimes known as *Brazilian balsam* or as *Oleo-Balsam*, has been offered for sale as genuine Peru balsam. In bulk it is of a dark brown color, but in thin layers it is dark red. Its odor is smoky, feebly fragrant; its taste slightly pungent, leaving a choking, disagreeable, persistent feeling. It is entirely soluble in ether and in rectified spirits. It also mixes with castor oil in all proportions, forming with carbon disulphide a clear light brown solution with residue, and in the deposit, by its chloroform solution, of a powdery precipitate upon standing. At 17° C. its specific gravity is 1·031. Its general constitution is very similar to that of Balsam of Peru, containing volatile oil, myroxylin, cinnamic and tannic acids, and resin. (*P. J. Tr.*, 3d ser., xi. 818.) It is especially to be distinguished from Peru Balsam by its behavior with sulphuric acid. When Peru Balsam is treated with sulphuric acid, and cold water poured upon it, a beautiful violet is imparted to the surface, and the whole mass has a bright shade. The same procedure yields with the Oleo-Balsam a gray mass. For further information see *P. J. Tr.*, xv. 771.

Toluifera pereiræ ; Myroxylon pereiræ, Klotzsch ; *Myrospermum pereiræ*, Royle et Auctores ; "*Myrospermum of Sonsonate*," Pereira ; is a handsome tree, with a straight, round, lofty stem, a smooth ash-colored bark, and spreading branches at the top. The leaves are alternate, petiolate, and unequally pinnate. The leaflets are from five to eleven, shortly petiolate, oblong, oval-oblong, or ovate, about three inches long by somewhat less than an inch and a half in breadth, rounded at the base, and contracting abruptly at top into an emarginate point. When held up to the light they exhibit, in lines parallel with the primary veins, beautiful rounded and linear pellucid spots. The common and partial petioles and midribs are smooth to the naked eye, but when examined with a microscope are found to be furnished with short hairs. The fruit, including the winged footstalks, varies from two to four inches in length. At its peduncular extremity it is rounded or slightly tapering ; at the top enlarged, rounded, and swollen, with a small point at the side. The mesocarp, or main investment of the fruit, is fibrous, and contains in distinct receptacles a balsamic juice, which is most abundant in two long receptacles or vittæ, one upon each side. The yellowish-white beans yielded to Mr. Rother (*P. J. Tr.*, xv. 244) two per cent. of coumarin ; the husks, a brown, extremely bitter, somewhat acrid resin. A gum-resin exudes in small quantities from the trunk of the tree, which, though containing, besides gum and resin, a small proportion of volatile oil, is distinct from the proper balsam, and yields no cinnamic acid. (Attfield, *P. J. Tr.*, Dec. 1863.)

This tree grows in Central America, in the State of San Salvador, upon the Pacific coast. It is found in the wild forests, singly or in groups, but the trees are owned by individuals. Dr. Charles Dorat states that it is never found at a greater height on the mountains than one thousand feet, that it begins to be productive after five years, and continues to yield for thirty years or more, and that the aroma of its flower is perceived at the distance of one hundred yards. (*A. J. P.*, xxxii.) The balsam is collected by the aborigines, on lands reserved to them, within a small district denominated the Balsam Coast, extending from Acajutla to Port Libertad. Early in November or December the bark is beaten on four sides of the trunk, so as to separate it from the wood without breaking it ; intermediate strips being left sound, in order not to destroy the life of the tree. The bruised bark soon splits, or cuts are made in it. Five or six days after the beating the injured surface is set on fire, and about a week later the bark, if it has not fallen off spontaneously, is removed. The juice now begins to exude freely from the exposed wood, which the natives cover with rags. The latter, when saturated, are boiled in water in large jars, and the liquid allowed to stand ; whereupon the water rises to the top, and is poured off, leaving the balsam, which is put into calabashes or bladders. It is then taken for sale to the neighboring towns, where it is purified by subsidence and straining and put into jars or metallic drums for exportation. The destroyed bark is said to renew itself in two years, so that by care a tree can be long worked ; two pounds is stated to be the average yearly yield. In 1861 the tree was introduced in Ceylon with complete success.

A substance called *white balsam* (*Balsamo blanco*) is procured from the fruit by expression. This has been confounded with the balsam of Tolu, but is wholly distinct. It is of a semi-fluid or soft-solid consistence, somewhat granular, and, on standing, separates into a white resinous crystalline deposit, and a superior translucent more fluid portion. The smell, though quite distinct from that of the balsam of Tolu and Peru, is not disagreeable. Dr. Stenhouse has obtained from it a peculiar resinous body, readily crystallizable, and remarkably indifferent in its chemical affinities, which he denominates *myroxocarpin*. (*P. J. Tr.*, x. 290.) Dr. Dorat, however, denies that the white balsam is produced by the same tree, or in the same vicinity.

Another substance obtained from the same tree, and much used in Central America, is a tincture of the fruit made by digesting it in rum. It is called *balsamito* by the inhabitants, and is said to be stimulant, anthelmintic, and diuretic. It is also used as an external application to gangrenous or indolent ulcers, and as a wash to the face to remove freckles. According to Dr. Dorat, the balsamito is not the tincture, but an alcoholic extract of the young fruit. Neither this nor the white balsam reaches the markets of this country.

The balsam of Peru was named from its place of exportation ; and it was long thought to be a product of Peru. It is now shipped partly from the Pacific coast, and partly from the Balize or other Atlantic ports, whither it is brought across the country. It was Guibourt who first made known the fact of its exclusive production in Central America. As imported, it is usually in tin canisters, with a whitish scum on its surface, and more or less deposit, which is dissolved with the aid of heat.

Properties. Balsam of Peru is viscid like syrup or honey, of a dark reddish-brown color, a fragrant odor, and a warm bitterish taste, leaving when swallowed a burning or prickling sen-

sation in the throat. When exposed to flame it takes fire, diffusing a white smoke and fragrant odor. Containing resin, volatile oil, and both benzoic and cinnamic acids, it is properly considered a balsam, though probably somewhat altered by heat. "A liquid having a syrupy consistence, free from stringiness or stickiness, of a brownish-black color in bulk, reddish-brown and transparent in thin layers, of an agreeable vanilla-like, somewhat smoky odor, and a bitter taste, leaving a persistent after-taste. On exposure to air it does not become hard. Specific gravity, 1·135 to 1·150 at 15° C. (59° F.). Miscible, in all proportions, with absolute alcohol, chloroform, or glacial acetic acid; only partially soluble in ether or benzin. It is completely soluble in 5 parts of alcohol." *U. S.* Boiling water extracts the acid. The oily liquid which separates on agitating Peru balsam with caustic potash or soda, called *Peru balsam oil* by Stolze, *cinnamein* by Frémy, may be separated by fractional distillation into three portions,—viz., *benzyl alcohol*, C_7H_8O, passing over at about 200° C. (392° F.); *benzylic benzoate*, $C_7H_5O_2,C_7H_7$, the principal portion, boiling at 303°–304° C. (577·5°–579° F.); and *benzylic cinnamate*, $C_9H_7O_2,C_7H_7$, passing over at about the boiling point of mercury. The crude oil likewise contains small quantities of free cinnamic and benzoic acids, resulting from the decomposition of the benzylic ether by the alkali used in separating it, and equivalent to the free benzylic alcohol also contained in it. According to Kraut (*Ann. Ch. Pharm.*, 153, p. 129), the benzylic cinnamate constitutes nearly 60 per cent. of the balsam; but Trog (*Archiv d. Pharm.*, 1894, 70–98) states that it is the benzyl benzoate which makes up the bulk of the oily portion and amounts to from 63 to 64 per cent.

Peru balsam appears to contain only a single resin, yielding, by analysis, 66·3 to 67·25 per cent. of carbon, and 6·22 to 6·32 per cent. of hydrogen (Kraut, *loc. cit.*). This resin separated from the alkaline solution of the balsam by hydrochloric acid is brown, has a faint odor of vanilla, and when fused with potash yields protocatechuic acid, together with a little benzoic acid. The resin yielded about two-thirds its weight of protocatechuic acid. (Kachler, *Zeitsch. für Ch.*, [2] 6, 59.) The tree also exudes a gum-resin, which, according to Attfield (*P. J. Tr.*, 1864, p. 248), contains 77·4 per cent. of a resin, and is non-aromatic, devoid of cinnamic acid, and entirely distinct from balsam of Peru. The leaves of the tree contain a fragrant oil. Trog found the fluid portion of the balsam to consist almost entirely of *benzyl benzoate*, with small quantities of *cinnamic acid*, *vanillin*, and *benzyl cinnamate*. The resin, he states, is an ester. Like benzoin, balsam of Peru appears to be a pathological product.

The balsam is said to be adulterated in Europe (especially at Bremen) with castor oil, copaiba, Canada turpentine, etc. (*P. J. Tr.*, xii. 549); and a factitious substance has been sold in this country for the genuine balsam, prepared by dissolving balsam of Tolu in alcohol. This may be distinguished by its taking fire readily and burning with a blue flame. (*N. Y. Journ. of Pharm.*, i. 133.) The British Pharmacopœia gives the following tests. "1 volume is soluble in 1 volume of *alcohol* (90 per cent.), but on the further addition of 2 or more volumes of the *alcohol*, the mixture becomes turbid. Specific gravity between 1·137 and 1·150. 10 drops triturated with 0·4 gramme of *lime* produce a permanently soft mixture (absence of copaiba and resins); and this, on being warmed until all volatile matter is given off and until charring commences, gives no fatty odor (absence of castor oil and other fatty oils). It should not diminish in volume when shaken with an equal bulk of *water* (absence of ethylic alcohol). About 40 per cent. of resin should separate when one part of the Balsam is treated with three parts of *carbon bisulphide;* and the clear supernatant liquid should be of a pale brown color with only a slight fluorescence (absence of gurjun balsam). If 5 grammes of the Balsam be shaken with 5 cubic centimetres of a solution of *sodium hydroxide* of specific gravity 1·16, and then washed with three successive quantities, each of 15 cubic centimetres, of Purified Ether, and the Ether removed, the residue (after cautious drying until the loss, in two weighings at 5 minutes' interval, does not exceed one centigramme) should weigh between 2·85 and 3 grammes. To this weighed residue 20 cubic centimetres of *normal volumetric alcoholic solution of potassium hydroxide* and 40 cubic centimetres of *alcohol* (90 per cent.) are to be added and the whole saponified under a reflux condenser for one hour. Thus treated, the residue above specified should combine with from 11·9 to 12·8 cubic centimetres of the *normal volumetric alcoholic solution of potassium hydroxide* (presence of a sufficient proportion of cinnamein). The amount of uncombined alkali may be determined in the usual way by means of titration with the *volumetric solution of sulphuric acid*." For additional tests, see *Proc. A. P. A.*, 1894, 903; also 1895, 866, and *Drug. Circ.*, 1898, 60. A method of detecting castor oil, proposed by Dr. Wagner, is to expose a small portion of the suspected balsam to distillation until somewhat more than one-half has passed, to shake the distillate with baryta water, to

remove by means of a pipette the layer of oil floating on the surface, and to shake this with a concentrated solution of sodium bisulphite. If castor oil be present, the liquid will immediately become a crystalline mass. (*A. J. P.*, xxx. 570.) The official tests of purity are as follows. "Water agitated with a portion of the Balsam reddens blue litmus paper. If 1 C.c. of carbon disulphide be mixed with 3 C.c. of the Balsam, contained in a dry test-tube, a clear liquid will result. On now adding 8 more C.c. of carbon disulphide and agitating, the resinous constituent of the Balsam (amounting to about 15 per cent.) will adhere to the walls of the tube, and the liquid portion will be clear, of a tint not deeper than light brownish, and not more than faintly fluorescent (absence of *gurjun balsam*). If 2 C.c. of the Balsam be vigorously shaken, in a dry test-tube, with 8 C.c. of benzin, so that the Balsam may be spread over the walls of the tube, and the liquid then immediately poured off, the Balsam should remain adherent to the walls for some minutes and subside slowly, while the liquid (which should be filtered, if turbid) should be colorless or only faintly yellow, and should deposit no sediment on standing (absence of appreciable quantities of *storax*, *turpentine*, *copaiba*, etc.). If 10 drops of the Balsam be triturated, in a small mortar, with 20 drops of sulphuric acid, a tough, homogeneous, brownish-red mass will result, which, when washed with cold water, should, after a few minutes, be converted into a brittle, resinous mass (absence of *fixed oils*). On distilling water with a portion of the Balsam, no *essential oil* should pass over." *U. S.* Prof. Flückiger relies upon the specific gravity, which should be between 1·140 and 1·145, and the *lime test*, in which 10 drops of the balsam are shaken with 6 grains (0·4 Gm.) of slaked lime, forming, if there be no adulteration, a soft mixture, which does not harden. *Grote's test* consists in shaking 3 drops of balsam with 2 C.c. of official ammonia water; if, after standing, the mixture solidifies, colophony or other adulterant is present: benzoin, storax, and certain other substances cannot be detected by this test. (*A. J. P.*, 1881, 302, 361.)

As stated by Trog and others, the percentage of cinnamein should approximate 60. The saponification number should be between 235 and 238.

Medical Properties and Uses. This balsam is a warm stimulating stomachic and expectorant, and has been recommended in *chronic catarrhs*, certain forms of *asthma*, *phthisis*, and other *pectoral complaints* attended with debility. It has also been used in *gonorrhœa*, *leucorrhœa*, *amenorrhœa*, *chronic rheumatism*, and *palsy*. At present, however, it is little employed by American physicians. As an external application it has been found beneficial in *chronic indolent ulcers* and in *local tuberculosis of skin*, *bone*, *larynx*, etc. The dose is half a fluidrachm (1·9 C.c.). It is best administered diffused in water with sugar and the yolk of egg or gum arabic, or in smaller doses dropped on a lump of sugar. When prescribed as an addition to expectorant mixtures, sufficient mucilage of acacia should be ordered with it to suspend it properly.*

BALSAMUM TOLUTANUM. U. S., Br. Balsam of Tolu.

(BĂL'SĄ-MŬM TŌ-LŪ-TĀ'NŬM.)

"A balsam obtained from Toluifera Balsamum, Linné (nat. ord. Leguminosæ)." *U. S.* "A balsam obtained by making incisions in the trunk of Myroxylon Toluifera." *Br.*

Baume de Tolu, Baume de Carthagène, *Fr.;* Tolubalsam, *G.;* Balsamo del Tolu, *It.;* Balsamo de Tolu, *Sp.*

Although Linnæus described this tree as a distinct species, Ruiz, one of the authors of the *Flora Peruviana*, considered it identical with *Myroxylon peruiferum;* but M. Achille Richard determined that it was distinct, and gave it the specific name of *toluiferum*, which was formerly adopted in both the Br. and U. S. Pharmacopœias. Very properly, however, the revisers of the U. S. Pharmacopœia have returned to the Linnæan name.

The balsam is procured by making V-shaped incisions in the trunk quite through the bark. The juice is received in small calabash cups, which are inserted in slight excavations beneath the point of the two vertical incisions meeting at the lower end; and Mr. Weir has seen as many as twenty cups at a time on one tree. The collectors go from tree to tree, emptying the cups into flasks of raw hide. In these skin vessels the juice is taken to the different ports on the river, where it is transferred to tin cans. It is brought from Carthagena in calabashes or baked earthen jars, or in tin or glass vessels.

Properties. As first imported, balsam of Tolu has a soft tenacious consistence, which varies considerably with the temperature. By age it becomes hard and brittle like resin. It is shining, translucent, of a reddish or yellowish brown color, a highly fragrant odor, and a

* In the case of alleged fatal poisoning in a child six days old, reported by Dr. Lohaus (*Therap. Monatsch.*, March, 1892), it does not seem probable that the Peru balsam was the cause of the symptoms.

warm, somewhat sweetish and pungent, but not disagreeable taste. Exposed to heat, it melts, inflames, and diffuses an agreeable odor while burning. It is entirely soluble in volatile oils. The official description of it is as follows. "A yellowish-brown, semi-fluid or nearly solid mass, becoming more brittle when exposed to cold, transparent in thin layers, having an agreeable odor recalling that of vanilla, but distinct from it, and a mild, aromatic taste." "When pressed between pieces of glass with the aid of heat, it exhibits, when examined with a lens, an abundance of crystals." *Br.* The U. S. Pharmacopœia gives the following tests of purity. "Readily and completely soluble in alcohol, the solution showing an acid reaction with litmus paper. Also completely soluble in chloroform, and in solutions of the fixed alkalies; almost completely soluble in ether, but nearly insoluble in water, benzin, or carbon disulphide. Carbon disulphide, aided by a gentle heat, removes from the Balsam scarcely anything but some of its cinnamic and benzoic acids. On decanting and evaporating the disulphide, no substance having the properties of *resin* should remain." "It is soluble in *alcohol* (90 per cent.) and the solution has an acid reaction. If 5 grammes are gently warmed with two successive portions of 25 and 10 cubic centimetres of *carbon bisulphide*, the solution should yield, when evaporated to dryness, a distinctly crystalline residue which should require not less than one-third of its weight of *potassium hydroxide* for its saponification (presence of a sufficient proportion of benzoates and cinnamates)." *Br.* The latter test is based upon Braithwaite's researches upon spurious balsams of Tolu. (See *P. J. Tr.*, 1895, 145; also 1897, 307.) Boiling water extracts its acid. Distilled with water it affords a small proportion of volatile oil; and, if the heat be continued, an acid matter sublimes. Mr. Hatchett states that when dissolved in the smallest quantity of solution of potassa it loses its own characteristic odor and acquires that of the clove pink. G. L. Ulex gives as a test of the purity of the balsam, that if heated in sulphuric acid it dissolves without disengagement of sulphurous acid, and yields a cherry-red liquid. (*Archiv der Pharm.*, Jan. 1853.) A modification of this test is that of R. A. Cripps (*P. J. Tr.*, xix. 1888), who states that by a comparative test of the suspected balsam with a pure specimen 1 per cent. of storax or other resinous adulterant can be detected. Thirty grammes of the sample are digested in carbon disulphide for fifteen minutes with general warmth, the clear liquid decanted, evaporated to dryness, and dissolved in sulphuric acid. A bright-red rose color is produced, remaining rose for a length of time if the balsam be pure, rapidly becoming brown if the balsam have been adulterated. The balsam is a mixture of volatile oil, free acid, and resin. The volatile oil is obtained by distilling the balsam with water, and may amount to a little over 1 per cent. This oil is chiefly *tolene*, $C_{10}H_{16}$, boiling at 170° C. (338° F.), and rapidly hardening by absorption of oxygen from the air. The free acid, according to Deville and Scharling, consists of benzoic and cinnamic acids, which statement has been confirmed by Flückiger. (*Pharmacographia*, 2d ed., 204.) Busse (*Ber. Chem. Ges.*, 1876, 833) has shown, moreover, that the benzylic ethers of both cinnamic and benzoic acids are present in the balsam, the benzyl cinnamate in larger amount.

According to Kopp, there are two resins in Tolu balsam, one easily soluble in alcohol, $C_{18}H_{19}O_4$, and another sparingly soluble, $C_{18}H_{20}O_5$. According to Deville, however, there is only one resin, that to which the second formula belongs. Trommsdorff obtained 88 per cent. of resin, 12 of acid, and only 0·2 of volatile oil. According to Mr. Heaver, the balsam yields by distillation about one-eighth of its weight of pure cinnamic acid. The acid distils over in the form of a heavy oil, which condenses into a white crystalline mass. It may be freed from empyreumatic oil by pressure in bibulous paper, and subsequent solution in boiling water, which deposits it in minute colorless crystals upon cooling. (*A. J. P.*, xv. 77.) A later investigation by Oberländer shows that the resinous portion of the balsam consists of *tolu-resino-tannol* in combination with cinnamic and benzoic acids, the latter in small proportion only. The balsam contains, in addition, 7·5 per cent. of an aromatic, acid, oily liquid, composed mainly of benzyl benzoate, with a little benzyl cinnamate and a trace of vanillin. (*Archiv d. Pharm.*, 1894, 599.) A factitious balsam described by Dr. R. V. Mattison (*A. J. P.*, 1876, 51) contained 63 per cent. of storax.

Medical Properties and Uses. Balsam of Tolu is a feeble stimulant expectorant; the syrup of Tolu is much used, on account of its agreeable flavor, as the basis of cough-mixtures. Old and obstinate *catarrhs* are said to be sometimes greatly relieved by the inhalation of the vapor proceeding from an ethereal solution of this balsam. Dose, from ten to thirty grains (0·65–1·95 Gm.), frequently repeated. The best form of administration is that of emulsion, made by triturating the balsam with mucilage and loaf-sugar, and afterwards with water.

BARII DIOXIDUM. U. S. Barium Dioxide. [Barium Peroxide.]

BaO_2; 168·82. (BĀ′RĮ-Ī DĪ-ŎX′Į-DŬM.)

"Commercial, anhydrous Barium Dioxide. It should be kept in well-closed vessels." *U. S.*

This compound of barium is introduced into the U. S. Pharmacopœia of 1890 for the first time. It is used solely for making hydrogen dioxide. Barium forms two oxides, BaO and BaO_2: the former is produced by the action of oxygen or dry air on barium. Barium Dioxide, BaO_2, is made by heating barium oxide to about 450° C., when it takes up another atom of oxygen. It is "a heavy, grayish-white, or pale yellowish-white, amorphous, coarse powder, odorless and tasteless. When exposed to the air, it slowly attracts moisture and carbon dioxide, and is gradually decomposed. Almost insoluble in cold water, with which, however, it forms a definite hydrate, and to which it imparts a decidedly alkaline reaction. Hydrochloric, phosphoric, and most other mineral acids decompose it, producing the corresponding barium salts, and hydrogen dioxide, which remains in solution for a considerable time, if the reaction have taken place in the cold, and an excess of the acid be present. When heated to a bright red heat, Barium Dioxide fuses, loses oxygen, and is reduced to barium oxide. Barium Dioxide should be dissolved by diluted hydrochloric or phosphoric acid without leaving more than a trace of residue. If 2·11 Gm. of Barium Dioxide be dissolved, as completely as possible, in ice-cold water to the volume of 25 C.c., with the aid of 7·5 C.c. of phosphoric acid, and 5 C.c. of this solution (corresponding to 0·422 Gm. of the Dioxide) be measured off for assay, it should require not less than 40 C.c. of potassium permanganate decinormal volumetric solution to impart to the liquid a permanent pink tint, corresponding to not less than 80 per cent. of pure Barium Dioxide (each C.c. of the volumetric solution indicating 2 per cent. of the latter)." *U. S.*

Barium Dioxide is not used medicinally.

BARIUM. Barium.

Ba; 136·8. (BĀ′RĮ-ŬM.) Ba; 136·8.

This is the metal present in the earth baryta. It was first obtained in 1808 by Sir H. Davy, who described it as a difficultly fusible metal, of a silvery-gray color, decomposing water readily, and considerably heavier than sulphuric acid. When exposed to the air, it instantly becomes covered with a crust of baryta. Barium chloride and barium carbonate were formerly official.

Baryta (or barium oxide) may be obtained from the native carbonate by intense ignition with carbonaceous matter, or from the native sulphate by ignition with charcoal, which converts it into barium sulphide, subsequent solution of the sulphide in nitric acid, and strong ignition of the nitrate formed, to dissipate the acid. As thus obtained, it is an anhydrous solid, caustic, alkaline, difficultly fusible, and of a grayish-white color. Its sp. gr. is about 4. It acts on the animal economy as a poison. When sprinkled with water it slakes like lime, becomes hot, and is reduced to the state of a white pulverulent hydrate. The same hydrate is formed in mass when the anhydrous earth is made into a paste with water and exposed to a red heat in a platinum crucible. The excess of water is expelled, and the hydrate, undergoing fusion, may be poured out and allowed to congeal. Barium hydrate dissolves in water, and forms the reagent called *baryta water*. A boiling saturated solution, as it cools, yields crystals of barium hydrate containing eight molecules of water of crystallization.

Baryta consists of one atom of barium and one of oxygen. Its chemical formula is, therefore, BaO. When barium oxide is heated in a current of oxygen or air, it takes up an atom of oxygen and is changed into barium dioxide, BaO_2. When this is heated somewhat higher, it gives off the extra atom of oxygen and becomes BaO again. This power of taking up oxygen from the air and giving it up at a somewhat higher heat is now utilized on a commercial scale in the Brin process for making oxygen, and it is found that this change from BaO to BaO_2 and back again can be effected at one and the same temperature by simply heating first under pressure and then by exhausting and reducing below the normal atmospheric pressure. Barium dioxide is also of growing importance as the material from which hydrogen dioxide, H_2O_2, is made, and has been introduced into the U. S. Pharmacopœia of 1890. *Barium carbonate*, $BaCO_3$, is the native carbonate, a rare mineral, discovered in 1783 by Dr. Withering, in honor of whom it is called *witherite*. It is found in Sweden and Scotland, but most abundantly in the lead-mines of the north of England. It occurs usually in grayish, or pale yellowish-gray, fibrous masses, but sometimes crystallized. Its sp. gr. varies from 4·2 to 4·4. It is generally translucent, but sometimes opaque. It effervesces with acids, and, before the blow-pipe, melts into a white

enamel without losing its carbonic acid. It is distinguished from strontium carbonate, with which it is most liable to be confounded, by its greater specific gravity, and by its yielding a light greenish rather than a reddish flame upon the burning of alcohol impregnated with its solution in hydrochloric acid. The presence of strontium is indicated by a reddish flame.

When pure, barium carbonate is entirely soluble in hydrochloric acid. Any barium sulphate present is left undissolved. If neither ammonia nor hydrogen sulphide produces discoloration or a precipitate in the hydrochloric acid solution, the absence of aluminum, iron, copper, and lead is shown. Lime may be detected by adding an excess of sulphuric acid, which will throw down the baryta as a sulphate, and afterwards testing the clear liquid with sodium carbonate, which, if lime be present, will produce a precipitate of calcium carbonate.

Barium carbonate acts as a poison on the animal economy. Its only pharmaceutical use is to prepare barium chloride. (For *Barium Chloride* and *Barium Sulphate*, see PART II.)

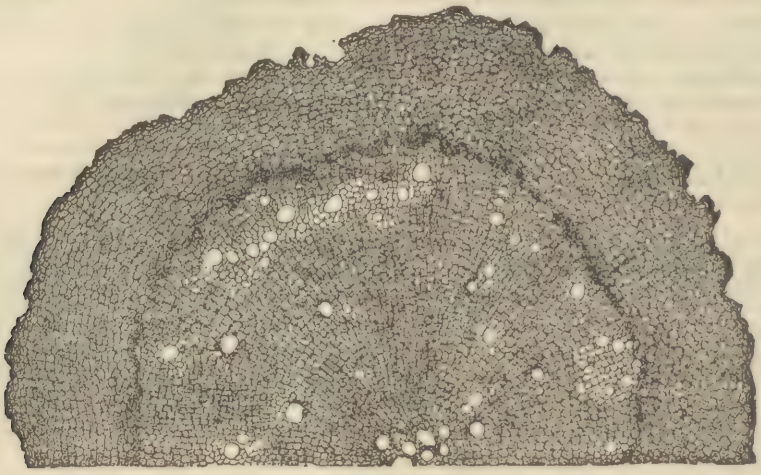
Gen. Ch. Corolla bell-shaped. *Stamens* distant. *Berry* globular, two-celled. *Willd.*



Atropa Belladonna. Willd. *Sp. Plant.* i. 1017; Carson, *Illust. of Med. Bot.* ii. 19, pl. lxv.; *B. & T.* 193. The belladonna, or *deadly nightshade*, is an herbaceous perennial, with a fleshy, creeping root, from which rise several erect, round, purplish, branching stems, to the height of about three feet. The leaves, which are attached by short footstalks to the stem, are in pairs of unequal size, oval, pointed, entire, of a dusky green on their upper surface, and paler beneath. The flowers are large, bell-shaped, pendent, of a dull reddish color, with solitary peduncles, rising from the axils of the leaves. The fruit is a roundish berry with a longitudinal furrow on each side, at first green, afterwards red, ultimately deep purple, slightly resembling a cherry, and containing, in two distinct cells, numerous seeds, and a sweetish violet-colored juice. The calyx adheres to the base of the fruit.

Belladonna Leaf. 1, epidermis of the under side, with stomata and hair; 2, piece of a bundle of wood vessel; 3, parenchymatous tissue of leaf, showing raphides.

The plant is a native of Europe, where it grows in shady places, along walls, and amidst rubbish, flowering in June and July, and ripening its fruit in September. It grows vigorously under cultivation in this country, and retains all its activity, as shown by the observations of Mr. Alfred Jones. (*A. J. P.*, xxiv. 106.) All parts of it are active. The leaves and roots are directed by the United States and British Pharmacopœias, the latter including the young branches, which are probably not less efficient. The leaves should be collected in June or July, when the plant is in flower, the roots in the autumn or early in the spring, and from plants three years old or more. Leaves which have been kept long should not be used, as they undergo change through absorption of atmospheric moisture, emitting ammonia, and probably losing a portion of their active nitrogenous matter. It has been affirmed that the finest-looking leaves are to be rejected, as probably being those of cultivated plants, and inferior in strength to the smaller and less sightly leaves of the wild plant. (*A. J. P.*, xxvii. 455.) This is, however, probably an error, as the analyses made by Mr. A. W. Gerrard (*P. J. Tr.*, xv. 153) show that while the wild belladonna plant contains a little more alkaloid than the cultivated, the difference is not sufficient to be of material consequence. The same investigator found that the

leaf yields the alkaloid most abundantly, the root, fruit, and stem being the next in order, and that the period of flowering, between two and four years of age, is the best time for collecting the plant. The dried leaves as they occur in the American market appear to vary remarkably in the percentage of alkaloid; the best are fully equal to the finest English leaves. Specimens which contain much stem or are musty should always be rejected, as weak in active principle. Mr. Holmes has found in the English market the root of *Medicago sativa* used as an adulterant. (*P. J. Tr.*, 1882.)

Transverse section of Belladonna Root.

Properties. "Leaves from 10 to 15 Cm. long, from 5 to 10 Cm. broad, broadly ovate, equilaterally narrowed into a petiole, tapering at the apex, entire on the margin, smooth, thin, the upper surface brownish-green, the lower surface grayish-green, both surfaces whitish punctate; odor slight; taste bitterish, disagreeable." *U. S.* "The transverse section of the leaf exhibits bi-collateral vascular bundles; the mesophyll contains numerous cells filled with very minute crystals of calcium oxalate." *Br.* The roots occur "in cylindrical, somewhat tapering, longitudinally wrinkled pieces, 10 to 25 Mm. or more in thickness; externally brownish gray, internally whitish; fracture nearly smooth and mealy, not radiating or showing medullary rays in the thicker roots, only in the layer near the bark; nearly inodorous; taste sweetish, afterwards bitterish and strongly acrid. Roots which are tough and woody, breaking with a splintery fracture, should be rejected; likewise the hollow stem-bases which are sometimes present."* *U. S.* The bark of the belladonna root is thick, presenting immediately under

* *Scopolia.* In 1771, Dr. John Anthony Scopoli, of the University of Pavia, described in the *Flora Carniolica* an *Atropa* from Idria. Three years later, Jacquin made this plant the type of the new genus *Scopolia*, and gave it the specific name of *carniolica*. Of this plant Koch made two species, one with green and the other with purple flowers, but the more recent botanists are in accord in believing that the green-flowered plant, the *Scopolia kladnikiana* of Koch, the *Scopolia viridiflora* of Rabenhorst, is not specifically distinct, there being, indeed, three varieties of *S. carniolica*, one with purple, one with green, and one with yellow flowers, the latter being the *S. concolor* of De Candolle: indeed, E. M. Holmes has shown that the root examined by Schmidt was probably from a plant with yellow flowers, and therefore the *concolor* of De Candolle. *Scopolia atropoides* has also been described by Nevinny. (*Pharm. Post*, 1894, 333, 349, 357.)

The genus *Scopolia* (often spelled *Scopola*) is the connecting link between *Atropa* and *Hyoscyamus*, resembling *Atropa* in leaf and flower and in the microscopical character of its rhizome, but differing in that its fruit is not a berry and in the inflation of its calyx. The Japanese plant, *S. japonica*, is so closely allied to *S. carniolica* that its specific distinctness is very doubtful; it has been separated upon the characters of the style being curved, the calyx-teeth unequal, and the leaves less obovate and having much longer petioles than *S. carniolica*; but Holmes has shown that the curved style occurs in *S. carniolica*. *Scopolia carniolica* is a common plant in Bavaria, Austro-Hungary, and southwestern Russia, usually in the hilly districts, where it grows in damp, stony places. Its general appearance is that of the belladonna, but it is much shorter, rarely growing above a foot in height, has thinner leaves, and is especially distinguished by its fruit being a transversely dehiscent capsule and by the presence of a distinct rhizome. The latter occurs in commerce either entire or longitudinally split in half, in pieces from two to five inches in length and from one-third to three-fourths or even one inch in diameter; of a grayish-brown color, very irregular in shape, often much bent or twisted, the whole surface usually covered thickly with the broad, subcircular, deeply-hollowed-out, projecting scars of the stems of successive seasons, and finely and coarsely wrinkled longitudinally and transversely. The section is whitish and distinctly starchy in appearance. The texture is hard, but somewhat brittle. The taste is slightly bitter, and disagreeable.

the epidermis a dark line composed of from six to eight layers of tabular cells. The bark itself is composed entirely of parenchymatous cells, more or less filled with muller-shaped starch grains, which are often united in the cells into compound grains. Bundles of raphides, probably of calcium oxalate, are usually very evident. As to the relative strength of these two parts, M. Hirtz, of Strasburg, inferred from his experiments that the root yields an extract five times stronger than that obtained from the leaves, but did not determine the relative yield of extract; whilst Lefort obtained from young roots 0·6, from old roots 0·25, and from dried leaves 0·44 per cent. of atropine; and Dragendorff obtained 0·66 from dried leaves, and 0·4 per cent. from the roots. (*Jahresb.*, 1874, p. 96.) Both the leaves and root, as well as all other parts of the plant, impart their active properties to water and alcohol. Brandes rendered it probable that these properties reside in a peculiar alkaline principle which he supposed to exist in the plant combined with an excess of malic acid and appropriately named *atropine*. Besides atropine malate, Brandes found in the dried herb two principles, a green resin (chlorophyll), wax, gum, starch, albumen, lignin, and various salts. The alkaloid principle was first, however, procured in a state of purity by Mein, a German apothecary, who extracted it from the root.* Ladenburg (1879–1884) exhaustively studied the several sources of atropine and the allied alkaloids that exert a mydriatic action, and found that there are three alkaloids, *atropine*, *hyoscyamine*, and *hyoscine*, which possess the common formula $C_{17}H_{23}NO_3$, and in belladonna root, *belladonine*, $C_{17}H_{23}NO_4$. Of these, atropine occurs in the *Atropa belladonna* and in *Datura stramonium*, hyoscyamine in these plants and also in *Hyoscyamus niger* and *Duboisia myoporoides*; hyoscine is found in *Hyoscyamus niger* alone, and belladonine in belladonna root alone. The first of the alkaloids of the formula $C_{17}H_{23}NO_3$, *atropine*, fuses at 114° C.–115° C. (237·2° F.–239° F.), and forms a double gold chloride, fusing at 135° C.–137° C. (275° F.–278·6° F.); the second, the alkaloid known under the several names of *hyoscyamine*, *daturine*, and *duboisine*, fuses at 108·5° C. (227·5° F.), and yields a gold salt, fusing at 160° C.–162° C. (320° F.–323·6° F.); and the third, *hyoscine*, obtained as yet only in the form of a syrup, but forming a crystalline gold salt, which fuses at 198° C.–200° C. (388·4° F.–392° F.), and is less soluble than the hyoscyamine gold salt. In *Duboisia myoporoides* (see PART II.) the only alkaloid present seems to be the second of these, and the complete identity of it with the purified alkaloid of *hyoscyamus* has been established by Ladenburg, both by analysis of the free alkaloid and its salts, and by study of the action of different reagents upon it.† Hyoscyamine is more soluble in water and dilute alcohol than atropine, and, as already stated, forms a gold salt of different fusing point. Its decomposition products under the influence of caustic baryta or hydrochloric acid are the same as those of atropine,—viz., *tropine* and *tropic acid*. Regnauld

The Japanese rhizome is from two to six inches long, about one-half inch in diameter, rarely branched, cylindrical or slightly compressed, knotty, bent, with circular disk-like scars, of a pale brown color, not whitish when abraded, with a slightly mousy, narcotic odor, and a taste nearly free from bitterness. According to Mr. Thos. Greenish, the microscopical characteristics of the rhizome of *Scopolia carniolica* are very similar to those of belladonna root, the chief differences being that the bark is less thick, the dark line under the epidermis narrower, the vascular bundles neither so large nor so numerous, and the bundles of raphides less pronounced; the starch grains are also smaller and their shape less distinct. The structure of the rhizome of *S. japonica* was found to be the same as that of the European species.

Chemistry. The alkaloid *scopolamine* (or *scopoleine*), $C_{17}H_{21}NO_4$, has been found to be the characteristic constituent of the root, but is also found in small quantities in belladonna root, stramonium seeds, and *Duboisia myoporoides*. Prof. E. Schmidt considers scopolamine to be identical with hyoscine. (*Archiv d. Pharm.*, 1892, 206–232.) Scopolamine forms permanent transparent crystals of the formula $C_{17}H_{21}NO_4 + H_2O$, melting at 59° C. to a colorless liquid. The double gold chloride melts at from 212°–214° C. Scopolamine is decomposed by baryta into *scopoline*, $C_8H_{13}NO_2$, a crystalline base, melting at 110° C., and *atropic acid*, $C_9H_8O_2$. Commercial hyoscine hydrobromide is said by E. Schmidt often to consist almost entirely of scopolamine hydrobromide, and Hesse has considered the two bases as identical. (*Archiv d. Pharm.*, 1894, 409.) Dr. O. Hesse examined commercial scopolamine hydrochloride, and found it to consist of salts of two bases, hyoscine and *atroscine*. (*P. J. Tr.*, 1896, 289.) Schmidt, continuing his investigations, proves that hyoscine is a mixture of scopolamine and some other body, and believes Hesse's atroscine to be optically inactive scopolamine. He doubts the existence of hyoscine as a distinct body. (*Apoth. Zeit.*, 1896.) Mr. Seward W. Williams states, as the result of the assay of many tons of the root of *Atropa belladonna* and of the rhizome of *Scopolia*, each of the best qualities occurring in the American market, that whilst the belladonna root yields on an average 0·50 per cent. of alkaloid, the scopolia yields 0·58 per cent.

Medical Properties. The physiological and medical properties of the scopolia rhizome are undoubtedly very similar to those of belladonna. If, as seems scarcely probable, the observation of Sir Dyce Duckworth, that scopolia is less apt than belladonna to dry the mouth and dilate the pupils when given internally, be confirmed, the drug may be more useful than the belladonna itself. At present scopolia rhizome is used very largely in America for the making of belladonna plasters, and probably also for the manufacture of atropine.

* It is probable that the state of growth affects the alkaloidal contents of belladonna roots, for, according to the researches of Prof. Schmidt (*Pharm. Zeit.*, Sept. 1889), roots one year old contained free atropin, with hyoscyamine, but in fresh old roots only hyoscyamine was present.

† Ladenburg collected additional facts and embodied them in a valuable historical sketch of these researches in the *Annalen*. (See *A. J. P.*, 1883, 463; 1884, 206.)

and Valmont have confirmed Ladenburg's results as far as atropine and hyoscyamine are concerned. (*A. J. P.*, Dec. 1881, 610.) Hübschmann (*Schweiz. Zeits. Pharm.*, 1858, 123) and Kraut (*Ann. der Ch. und Pharm.*, 148, 236) both described, under the name of *belladonine*, a second alkaloid extracted from belladonna. This *belladonine* and another alkaloid, *atropamine*, found at times in belladonna root, and obtained from the by-products of the manufacture of atropine, possess the formula $C_{17}H_{21}NO_2$, and are considered as anhydro-atropines. Both bases form varnish-like masses. Merck has isolated a base isomeric with Hesse's atropamine, which has been termed *apoatropine*, the salts of which are easily crystallizable. He asserts that atropamine and apoatropine are identical. Hesse, on the other hand, denies this assertion. (*Ann. d. Chem.*, 271, 10.) For the mode of preparing atropine, and its properties, see the article *Atropina*. Dunstan and Ransom have devised processes for isolating the alkaloids from the root and leaves which they assert are simple and accurate. (See *A. J. P.*, 1884, 277; *Proc. A. P. A.*, 1886, 392.) A. W. Adams states that only 53 per cent. of the atropine in belladonna leaves can be separated by these processes. (*Am. Drug.*, 1891, 328.) For other assays of belladonna leaves and root, see Schwickerath. (*Pharm. Rund.*, 1893, 282.) The British Pharmacopœia has adopted a process of assay for these alkaloids. (See *Extractum Belladonnæ Liquidum.*)

The imported belladonna, especially that from Germany, is occasionally adulterated. (See 15th edition U. S. D., page 284.) W. Will published (*Archiv f. Physiolog.*) in 1888 the results of an investigation undertaken at the request of the Schering manufactory to determine why the proportion of hyoscyamine and atropine in a root seems to vary with the method of working, and reached the surprising conclusion that hyoscyamine can be changed into atropine under a variety of circumstances, such as fusion, action of weak soda solution (even at ordinary temperatures), and of ammonia. The change of the optical activity of the hyoscyamine into the inactive atropine, the alteration of fusing point in the two alkaloids, and of their double gold chloride salts, all confirm the results of the investigation. (*Ber. der Chem. Ges.*, 1888, p. 1717.) These results were also confirmed by Schmidt. They were at first doubted by Ladenburg, but seem now to be admitted, the two alkaloids being stereo-isomeric, and capable of such change.

Medical Properties and Uses. The action of belladonna upon the system is that of atropine. (See page 246.) All parts of the plant are poisonous. It is not uncommon, in countries where it grows wild, for children to pick and eat the berries, allured by their fine color and sweet taste. Soon after the poison has been swallowed, its peculiar influence is experienced in dryness of the mouth and fauces, burning in the throat and stomach, great thirst, difficult deglutition, nausea and ineffectual retching, loss of vision, vertigo, and intoxication or delirium, with violent gestures and sometimes fits of laughter, followed by coma. A feeble pulse, cold extremities, subsultus tendinum, deep coma or delirium, and sometimes convulsions, precede death. To obviate the poisonous influence of the belladonna the most effectual method is to evacuate the stomach as speedily as possible, by means of emetics or the stomach-pump, and afterwards to cleanse the bowels by purgatives and enemata. The infusion of galls may be serviceable as an antidote. Both morphine and pilocarpine are to some extent physiologically antagonistic to atropine, and have been found very useful in belladonna poisoning. (See *Brit. Med. Journ.*, Feb. 1890.) They should be given hypodermically.

Belladonna has been used as a medicine from early times. The leaves were first employed externally to discuss *scirrhous tumors* and heal *cancerous* and other *ill-conditioned ulcers*, and were afterwards administered internally for the same purpose. Belladonna has acquired considerable credit as a preventive of *scarlatina*,—an application of the remedy first suggested by the author of the homœopathic doctrine,—but it is absolutely devoid of any such power. For further information, see *Atropine*.

The extract is much used locally. Rubbed upon the areola of the breast, it has been found to arrest the *secretion of milk;* and upon the abdomen, to relieve the *vomiting of pregnancy*, and other irritations sympathetic with the gravid uterus. In *cardiac diseases* the plaster is often applied with advantage over the heart. The decoction or extract, applied to the neck of the uterus, is asserted to have hastened *tedious labor* dependent on rigidity of the os tincæ; and spasmodic *stricture of the urethra*, *neck of the bladder*, and *sphincter ani*, *anal fissures*, and painful *uterine affections*, have been relieved by the local use of the extract, either smeared upon bougies or administered by injection. In the latter mode it has relieved *strangulated hernia*. It is asserted also to be useful in *paraphimosis*. The inhalation of the vapor from a decoction of the leaves or extract has been recommended in *spasmodic asthma*. For this purpose, two drachms of the leaves, or fifteen grains of the aqueous extract, are employed to the

pint of water. A much better plan is to smoke the dried leaves, either in the form of a cigarette or in a pipe. Relief is said to have been obtained in *phthisis* by smoking the leaves, infused when fresh in a strong solution of opium, and then dried.

Belladonna should never be given in substance, but in the form of extract or tincture, or, when accuracy or quickness of action is desired, of atropine. (See *Atropine*.)

BENZINUM. U. S. Benzin. [Petroleum Benzin. Petroleum Ether.]

(BĔN-ZĪ'NŬM.)

"A purified distillate from American petroleum, consisting of hydrocarbons, chiefly of the marsh-gas series [C_5H_{12}, C_6H_{14}, and homologous compounds]. Benzin should be carefully kept in well-stoppered bottles or tin cans, in a cool place, remote from lights or fire." *U. S.*

This useful product of petroleum was first introduced in the U. S. Pharmacopœia of 1880; it is obtained in the process of purifying petroleum by fractional distillation (see *Petroleum*, PART II.), and it is defined in the Pharmacopœia as "a transparent, colorless, diffusive liquid, of a strong, characteristic odor, slightly resembling that of petroleum, but much less disagreeable, and having a neutral reaction. Specific gravity, 0·670 to 0·675 at 15° C. (59° F.). Boiling point, 50° to 60° C. (122° to 140° F.). Insoluble in water; soluble in about 6 parts of alcohol, and readily soluble in ether, chloroform, benzol, and fixed and volatile oils. Benzin is highly inflammable, and its vapor, when mixed with air and ignited, explodes violently. On evaporating Benzin from the hand, it should leave no odor, and on evaporating it from a warmed dish, it should leave no residue (absence of *heavy hydrocarbons*). When it is boiled for a few minutes with one-fourth its volume of spirit of ammonia, and a few drops of silver nitrate test-solution, the ammoniacal liquid should not turn brown (absence of *pyrogenous products* and *sulphur compounds*). If 5 drops of Benzin be added to a mixture of 40 drops of sulphuric and 10 drops of nitric acid, in a test-tube, the liquid warmed for about ten minutes, and then set aside for half an hour, on diluting it, in a shallow dish, with water, it should not evolve the bitter-almond-like odor of nitro-benzol (difference from, and absence of, *benzol*)." *U. S.* Petroleum benzin must be carefully distinguished from benzol (now generally called benzene by chemists, and official in the British Pharmacopœia), a product derived from coal tar (see *Benzol*). Although the Pharmacopœia gives a test to distinguish an admixture with benzol, this adulteration of benzin is hardly likely to take place here in the near future, because of the great difference in price. The principal consumption of benzin at present is in the arts as a solvent, especially as a substitute for oil of turpentine, which it resembles very much in its solvent properties. In pharmacy it has been used: to deprive powdered drugs of their fixed oil by percolation (see *Charta Sinapis*); to obtain volatile oils by percolating the oily drug with the benzin and subsequently evaporating the mixture spontaneously; as a substitute for ether in making oleoresins; and for many other purposes to which it is adapted on account of its powers as a solvent. Benzin is a good solvent for fats, resins, rubber, and some of the alkaloids.

Dragendorff recommends the rectification of benzin by fractional distillation from lard, collecting the portion which distils below 45° C. We have found petrolatum to be efficient in retaining the impurities in the still.* Other methods of deodorizing benzin have been used, such as agitating it with fresh portions of mercury, allowing it to stand for two days, decanting and rectifying; agitating the benzin with sodium plumbate and rectifying; digesting litharge in a strong solution of soda and shaking the benzin with the mixture; agitation with animal charcoal and decantation.

BENZOINUM. U. S., Br. Benzoin.

(BĔN-ZŌ-Ī'NŬM.)

"A balsamic resin obtained from Styrax Benzoin, Dryander (nat. ord. Styraceæ)." *U. S.* "A balsamic resin obtained from Styrax Benzoin, Dryand., and probably from other species of Styrax, Linn. Known in commerce as Siam and Sumatra benzoin." *Br.*

Benzoe, *F.G.;* Resina Benzoe, Asa Dulcis; Gum Benjamin; Benjoin, *Fr.;* Benzöe, *G.;* Belzoino, *It.;* Benjui, *Sp.*

* Geo. M. Beringer (*A. J. P.*, 1890, p. 6) has found the following process useful for rapidly purifying benzin. Take of Potassium Permanganate, 1 ounce av.; Sulphuric Acid, ½ pint; Water, 3½ pints. Mix the acid and water, and when the mixture has become cold, pour it into a two-gallon bottle. Add the permanganate and agitate until it is dissolved. Then add Benzin, 1 gallon, and thoroughly agitate. Allow the liquids to remain in contact for 24 hours, frequently agitating the mixture. Separate the benzin and wash in a similar bottle with a mixture of Potassium Permanganate, ¼ ounce av.; Soda, ½ ounce av.; Water, 2 pints. Agitate the mixture frequently during several hours. Then separate the benzin and wash it thoroughly with water. The quantity of permanganate necessary is in direct proportion to the impurities existing in the benzin.

The botanical source of benzoin was long uncertain. At one time it was generally supposed in Europe to be derived from the *Laurus benzoin* of this country. This error was corrected by Linnæus, who, however, committed another in ascribing the drug to *Croton benzoë*, a shrub which he afterwards described under the name of *Terminalia benzoin*. Mr. Dryander was the first who ascertained the true benzoin-tree to be a *Styrax*. (*Lond. Phil. Trans.*, lxxvii.)

Gen. Ch. Calyx inferior. *Corolla* funnel-shaped. *Drupe* two-seeded. *Willd.*

Styrax benzoin. Willd. *Sp. Plant.* ii. 623; *B. & T.* 169. This is a tall tree of quick growth, sending off many strong round branches, covered with a whitish downy bark. Its leaves are alternate, entire, oblong, pointed, smooth above, and downy beneath. The flowers are in compound, axillary clusters, nearly as long as the leaves, and usually hang, all on the same side, upon short slender pedicels.

The benzoin- or *benjamin-tree* is a native of Sumatra, Java, Borneo, Laos, and Siam. By wounding the bark near the origin of the lower branches, a juice exudes, which hardens upon exposure and forms the *benzoin* of commerce. According to the researches of A. Tschirch (*Journ. Roy. Microscop. Soc.*, 1890), the exudation is purely the result of pathological processes, the plant containing no resin-receptacles. The trees, which are either wild or cultivated, are deemed of a proper age to be wounded at six years, when the trunks are usually about seven or eight inches in diameter. The operation is performed annually, and the product on each occasion from one tree never exceeds three pounds. The juice which first flows is the purest, and affords the whitest and most fragrant benzoin. It is exported chiefly from Bangkok in Siam, and Acheen in Sumatra. *Siam benzoin* is usually imported in cubical blocks, which take their form from the wooden boxes in which the soft resin has been packed. It is brittle, with a peculiar, vanilla-like fragrance, but bitter taste. It may be a compact mass, containing more or less numerous opaque white tears embedded in a rich amber-colored translucent resin, mixed to a greater or less extent with bits of bark, wood, etc. In some specimens these tears are exceedingly small, in others almost wanting. The finest variety is composed almost entirely of these tears, loosely agglutinated together. The tree which yields the Siam benzoin is stated to grow in an extremely circumscribed locality, on the bank of the river Mek-hong, occurring on high ground in clusters of from fifty to sixty trees. According to E. M. Holmes, its leaves are thinner and less distinctly venated than are those of the true Styrax Benzoin. In July and August the Siam trees are notched, and from these notches three months later the hardened benzoin is picked out. (See *Kew Bulletin*, 1895.) *Sumatra benzoin* differs from the Siam in having a much grayer color; the resin is grayish brown, the tears are usually fewer than in the finer variety, and the bits of wood, etc., more abundant. The odor differs from, and is less agreeable than, that of Siam benzoin. *Palembang benzoin* resembles Sumatra benzoin, but is somewhat more transparent, and is stated to yield a larger percentage of benzoic acid. It is also asserted that it can be distinguished by its tincture when dropped into water, not producing milkiness, but a flocculent deposit.* *Penang benzoin* also resembles Sumatra benzoin, but has an odor which is more like that of storax, and it is probably not yielded by the *Styrax benzoin;* possibly it is the product of one of the Sumatran species, *S. subdenticulata* and *S. porterianum*. For an account of the cultivation and collection of benzoin in Sumatra, by Mr. L. M. Vonck, see *Chem. and Drug.*, 1891, 486–488; also *Drug. Circ. and Chem. Gaz.*, 1891, 258. Lüdy made an investigation of the bark and wood of a benzoin tree brought from Java by Prof. Tschirch. He reached the conclusion that benzoin balsam was produced from the tannin of the bark. (*Arch. d. Pharm.*, 1893, 43, 95.)

Properties. Benzoin has a fragrant odor, with very little taste, but when chewed for some time leaves a sense of irritation in the mouth and fauces. It breaks with a resinous fracture, and presents a mottled surface of white and brown or reddish brown; the white spots being smooth and shining, while the remainder, though sometimes shining and even translucent, is usually more or less rough and porous, and often exhibits impurities. In the inferior kinds the white spots are very few, or entirely wanting. Benzoin is easily pulverized, and, in the process of being powdered, is apt to excite sneezing. Its sp. gr. is from 1·063 to 1·092. "In lumps consisting of agglutinated, yellowish-brown tears, which are internally milk-white, or in the form of a reddish-brown mass, more or less mottled from whitish tears embedded in it. It is almost wholly soluble in 5 parts of moderately warm alcohol, and in solutions of the fixed alkalies. When heated, it gives off fumes of benzoic acid. It has an agreeable, balsamic

* A factitious substance has been sold in our markets for benzoin, consisting of chips of wood agglutinated by a resinous substance, with no benzoic acid, and with only a trace of cinnamic acid. (J. M. Maisch, *A. J. P.*, xxxv. 494.)

odor, and a slight, aromatic taste." *U. S.* "It is almost entirely soluble in *alcohol* (90 per cent.) and in *solution of potassium hydroxide.*" *Br.* When heated it melts, and emits thick, white, pungent fumes, which excite cough when inhaled, and consist chiefly of benzoic acid. It is wholly soluble, with the exception of impurities, in alcohol, and is precipitated by water from the solution, rendering the liquor milky. It imparts to boiling water a notable proportion of benzoic acid. Lime water and the alkaline solutions partially dissolve it, forming benzoates, from which the acid may be precipitated by the addition of other acids. Its chief constituents are resin and benzoic acid; and it therefore belongs to the balsams. The white tears and the brownish connecting medium are said by Stolze to contain nearly the same proportion of acid, which, according to Bucholz, is 12·5 per cent., to Stolze, 19·8 per cent. In a more recent examination by Kopp, the white tears were found to contain from 8 to 10 per cent. of acid, and the brown 15 per cent. (*Journ. de Pharm.*, 3e sér., iv. 46.) The resin is of three kinds, one extracted with the benzoic acid by a boiling solution of potassium carbonate in excess, another dissolved by ether from the residue, and the third affected by neither of these solvents. Besides benzoic acid and resin, the balsam contains a little extractive and traces of volatile oil. Benzoin retards the oxidation of fatty matters, and thus tends to prevent rancidity.

It appears from recent researches that benzoin, besides its own characteristic acid, often contains also cinnamic acid, which is found more especially in the white tears. Indeed, Hermann Aschoff obtained from some benzoin of Sumatra a pure cinnamic acid, without any benzoic; and Messrs. Kolbe and Lautermann, upon examining a specimen of the tears, discovered what they at first supposed to be a peculiar acid, but which on further investigation proved to be a mixture of cinnamic and benzoic acids. H. Beckurts and W. Brueche confirm the statement that Siam benzoin contains no cinnamic acid, which is usually present in Sumatra benzoin. They found the specific gravity from 1·120 to 1·171; ash from 0·05 to 2·38 per cent.; portion insoluble in alcohol from 2·1 to 9 per cent. On the other hand, Lüdy (*Archiv d. Pharm.*, 1893, 500) extracted benzoic acid from Siam benzoin by the wet process. He found Sumatra benzoin to contain esters which yielded by saponification 32·9 per cent. of cinnamic acid, the proportion of esters being benzoresinol cinnamate, 7·4 per cent., and resinotannol cinnamate, 92·6 per cent.; at least 75 per cent. of Sumatra benzoin consisting of cinnamates yielding from 20 to 24 per cent. of cinnamic acid. (See also *Archiv d. Pharm.*, 1893, 461; *A. J. P.*, 1893, 223; and *Journ. de Pharm. et de Chim*, 1894, 172.) Benzoin may be rapidly tested for cinnamic acid by heating a small quantity with a little soda and water and warming the filtrate with potassium permanganate, when the odor of bitter almonds will be developed. (*Archiv d. Pharm.*, 1892, ccxxx.) Aschoff recommends the following method of detecting *cinnamic acid.* Boil the benzoin with milk of lime, filter, decompose with hydrochloric acid, and add either potassium bichromate with sulphuric acid, or potassium permanganate, when, if cinnamic acid be present, the odor of oil of bitter almond will be perceived. The two acids, which when they occur together in benzoin are said to be always mixed in equal proportion, may be at least partially separated by simple crystallization; their melting points being very different, that of benzoic acid 121° C. (249° F.), and that of the mixed acid, consisting of one part of the cinnamic and two of the benzoic, only 25·5° C. (78° F.). (*P. J. Tr.*, 1863, p. 77.) According to Mr. A. C. Curtis, *cinnamein* may be obtained by boiling benzoin with twice its bulk of lime in forty parts of water for fifteen or twenty minutes, filtering, cooling, adding hydrochloric acid, washing the precipitate, and recrystallizing from water acidulated with hydrochloric acid. (*A. J. P.*, 1872, p. 486.)

Rump (1878) treated Siam benzoin with caustic lime, precipitated the benzoic acid with hydrochloric acid, and agitated the liquid with ether. The latter on evaporating afforded a mixture of benzoic acid and *vanillin*, $C_8H_8O_3$. Subjected to dry distillation, benzoin affords as chief product benzoic acid, together with empyreumatic products, among which Berthelot has proved the presence (in Siam benzoin) of *styrol*, C_8H_8. The latter was also obtained in 1874 by Theegarten from Sumatra benzoin by distilling it with water. (*Ber. d. Chem. Ges.*, 1874, p. 727.)

Medical Properties and Uses. Benzoin is stimulant and expectorant, and was formerly employed in pectoral affections; but, except as an ingredient of the compound tincture of benzoin, it has fallen into disuse. Trousseau and Pidoux recommend strongly its inhalation in *chronic laryngitis.* Either the air of the chamber may be impregnated with its vapor by placing a small portion upon some live coals, or the patient may inhale the vapor of boiling water to which the balsam has been added. It is employed in pharmacy for the preparation of benzoic acid (see *Acidum Benzoicum*); and the milky liquor resulting from the addition of water to its alcoholic solution is sometimes used as a cosmetic, under the impression that it

renders the skin soft. A tincture has been strongly recommended in *anal fissure*. In the East Indies, the balsam is burnt by the Hindoos as a perfume in their temples.*

BENZOL. Br. Benzol.

C_6H_6; 77·82. (BĔN'ZŎL.)

"A mixture of homologous hydrocarbons obtained from light coal-tar oil. It contains about 70 per cent. of benzene, C_6H_6, and 20 to 30 per cent. of toluene, C_6H_5,CH_3." *Br.*

Benzene, Benzole, Phenyl Hydride, Benzen.

This substance must not be confounded with the commercial article sold as *benzin*, which is a mixture of various hydrocarbons of light specific gravity, obtained in the distillation of petroleum. (See *Benzinum.*) Originally the two names benzol and benzin were applied to the same substance, but after the discovery of petroleum it was found that the liquid obtained by distillation from coal tar was quite different from that obtained from petroleum. Little by little in the United States it has become the custom to call the liquid obtained by the fractional distillation of petroleum having the specific gravity 0·724 to 0·735 *benzin*. It is unfortunate that in Europe, and on the Continent especially, the term benzin is used for both liquids. The two substances are essentially different, although resembling each other in their solvent powers. Benzol is a definite hydrocarbon of fixed constitution; benzin a complex body of varying constitution. Benzol can be frozen; benzin has never yet been congealed. Benzin boils at from 54° C. (129·2° F.) to 56° C. (132·8° F.). Benzol can be converted into nitro-benzol, and by further treatment into aniline colors; benzin cannot. When benzin is shaken in the cold with one-third of its volume of fused crystals of absolute carbolic acid, the latter remains undissolved, whilst benzol is miscible with absolute carbolic acid in all proportions. (Allen.) According to Pusch, benzol can be distinguished from benzin by the fact that benzol forms a violet-red and benzin a raspberry-colored solution with iodine. (*A. J. P.*, xlvii. 268.) Although the term *Benzene* is given above as one of the synonymes of *Benzol*, its use abroad is gradually becoming limited to the pure hydrocarbon, C_6H_6, whilst *Benzol* is applied to the mixture of benzene with its homologues *Toluene*, *Paraxylene*, *Metaxylene*, *Mesitylene*, *Pseudo-cumene*, etc.

Benzol was discovered by Faraday in the condensed liquid from oil gas, and was next obtained by Mitscherlich by distilling benzoic acid with lime. It was afterwards discovered by Hofmann as a constituent of coal-gas tar. This tar, when distilled, furnishes *coal-naphtha* or light oil of tar, a complex substance, containing a number of hydrocarbons, among which is benzol. Upon distilling this naphtha from a metallic still, surmounted by an open vessel filled with water, and containing a worm terminating in a refrigerated receiver, the benzol will pass over and condense in the receiver; while the other substances associated with it, having higher boiling points, will condense in the worm and fall back into the still. The benzol is then purified by distillation at a heat between 80° C. (176° F.) and 90° C. (194° F.), and by subjecting the product to a new distillation from one-fourth of its volume of sulphuric acid. M. E. Kopp purifies benzol by taking advantage of its high congealing point. He exposes the impure mixture containing it to a degree of cold sufficient to solidify it (—15° C. or 5° F.), presses the congealed mass to separate the liquid hydrocarbons, allows it to become fluid, then again freezes and presses it, and thus obtains it almost entirely pure. He obtains the impure mixture containing the benzol by decomposing the heavier tar oils by a high degree of heat. (*Chem. News*, May 14, 1864, p. 229.)

Prof. Calvert, of Manchester, purifies coal-naphtha, so as to render it a sufficiently pure

* A styptic liquid, prepared by a Roman pharmaceutist named Pagliari, and kept secret for a time, has acquired some reputation among the French army surgeons. It is made by boiling, for six hours, eight ounces of tincture of benzoin (containing about two ounces of the balsam), a pound of alum, and ten pounds of water, in a glazed earthen vessel, stirring constantly, and supplying the loss with hot water. The liquor is then strained and kept in stopped bottles. It is limpid, styptic, of an aromatic smell, and said to have the property of causing an instantaneous coagulation of the blood. (See *Am. Journ. Med. Sci.*, N. S., xxv. 199.) M. Meyer, believing that the long boiling is injurious, if in no other way, by dissipating the benzoic acid, proposes to dispense with it, and has substituted the following formula, which furnishes a product always identical. Take tears of benzoin, 6 grammes (about ℥iss), alcohol at 90° C. 15 grammes; dissolve, and add of water 300 grammes, alum 30 grammes; mix, and boil till the liquid becomes clear. The liquid should mark 6° on the hydrometer. (*Journ. de Pharm. et de Chim.*, 4e sér., v. 123.)

Benzoin Alumina Cotton is recommended by Giulio Morpurgo as an efficient hæmostatic which does not stain the clothing. It is made by boiling solution of aluminum acetate with benzoin, straining, and at once impregnating the cotton. The prepared cotton is white and has a very pleasant odor; a considerable quantity of finely divided benzoin is separated upon the fibres, assisting by a mechanical action the astringent properties of the alumina. (*Pharm. Post*, 1893.)

benzol to be usefully applied to the purpose of removing fatty and oily matters from animal and vegetable substances, by subjecting it to the action of sulphuric acid, added in small quantities, so long as coloration is produced, then washing it with pure water, and afterwards subjecting it to distillation in an ordinary still. The sulphuric acid combines with the less volatile hydrocarbons present, which interfere with the solvent power of the benzol.

Prolonged treatment with sulphuric acid is also necessary to free the benzol from *thiophene*, C_4H_4S, an impurity which to the extent of about 0·6 per cent. is always present in commercial benzol. Its complete removal from the benzol is to be tested for by the *indophenin reaction* (blue coloration in presence of concentrated sulphuric acid and a small quantity of isatine).

In consequence of the great volatility and extreme inflammability of benzol and its attendant hydrocarbons, much care is necessary both in their preparation and in their subsequent use to avoid any possible exposure to flame. Very serious results have taken place from want of caution in this respect.

Properties. Benzol is a colorless limpid liquid, possessing an agreeable odor. Its sp. gr. is 0·85, congealing point 0° C. (32° F.), and boiling point 80° C. (176° F.). The British Pharmacopœia describes it as "A colorless volatile liquid free from opalescence, with a strong characteristic odor. Specific gravity from 0·880 to 0·888. It should begin to distil at 176° F. (80° C.), and about 90 per cent. of the whole should pass over at a temperature below 212° F. (100° C.). It should wholly distil below 248° F. (120° C.)." Its powers as a solvent are very extensive. Among the substances soluble in it are sulphur, phosphorus, and iodine, and most resins and fats. It dissolves quinine, but not cinchonine, with which it forms a bulky gelatinous mass. Morphine and strychnine are sparingly soluble. Its solvent power over some of the organic alkaloids led Mr. John Williams, of London, to employ it in extracting them. Dragendorff has corroborated and extended this use of benzol for obtaining the alkaloids, whose salts are, however, not usually soluble in the menstruum. Benzol is also a solvent of many of the resins, of mastic, camphor, wax, fatty and oily substances, essential oils, caoutchouc, and gutta-percha. It often becomes a matter of great importance commercially to test the purity of commercial benzol, and a very thorough method of assay based on fractional distillation is proposed by A. H. Allen, in his *Commercial Organic Analysis*, 1882. The following method, originating with Schorlemmer, is based on the conversion of this hydrocarbon into aniline, and of that into one of the characteristic colors derived from it. That part of the mixture which volatilizes at 150° C. (302° F.) is operated on. This is treated with fuming nitric acid, which, if benzol be present, gives rise to a nitrobenzol with its bitter-almond odor. The nitrobenzol is then converted by the action of granulated tin and hydrochloric acid into aniline, which is isolated by distilling the product with potassa. The aniline floats on the top of the liquid that passes. A little of this gives with sodium hypochlorite a fine purple color; and a drop of it, if heated with a little corrosive sublimate, will yield the beautiful color of rosaniline. (*Journ. de Pharm.*, 4e sér., ii. 177.) According to Balls, magnesium ribbon, with the addition of a few drops of solution of platinic chloride, rapidly and completely reduces nitrobenzene in alcoholic solution to aniline, giving a solution which can be at once decanted and tested with bleaching powder. (Allen.)

Medical Properties and Uses. It has been asserted by Naunyn, Wiederhold, and Possoz that benzol is an active germicide; but A. Chassevant found that it has no power of destroying the vitality of spores. (*Archiv. d. Pharmacodyn.*, vol. ii., 1896.) In Chassevant's experiments it rapidly produced complete coma in the lower animals, with muscular relaxation and greatly lowered temperature (10° C. without death). In the early stages of the poisoning tetanus and very rapid breathing were noticed. From one to two fluidounces of it are stated to have caused in man exhilaration and vertigo, followed by sleep and delirium (*Journ. de Pharm.*, 1861); but it is probably of no value in practical medicine. In the attempt to use it as an anæsthetic, Simpson, of Edinburgh, found that it caused violent constrictive headache and was scarcely capable of producing insensibility. According to Chassevant, it depresses arterial pressure by dilating the vessels, and acts most unfavorably on persons suffering from arterio-sclerosis or heart disease. According to M. Reynal, a mixture of ten parts of benzol, five of soap, and eighty-five of water is very destructive to human parasites, and does not affect the skin or the general system. Guyot states (*Brit. Med. Journ.*, 1897) that the habitual exposure to the fumes of benzol during its manufacture produces a chronic poisoning, characterized by uncertainty of gait, mental disturbance, wandering delirium, loss of sexual power, and epileptiform convulsions. Dose, from ten minims (0·62 C.c.) to half a fluidrachm (1·86 C.c.). According to Chassevant, *toluene* acts like *benzene*, but *xylene* is much more toxic, rapidly producing coma.

BISMUTHUM. Bismuth.

Bi; 208·9. (BĬŞ-MŪ'THŬM.) **Bi; 210.**

Etain de Glace, Bismuth, *Fr.;* Wismuth, *G.;* Bismutte, *It.;* Bismut, *Sp.*

Bismuth occurs usually in the metallic state, occasionally as a sulphide or a telluride, and rarely as an oxide. It is found principally in Saxony, Schneeberg being the chief point of production. It has been found at Monroe, in Connecticut, in Archer County, Texas (*A. J. P.*, 1871, 228), and in Colorado with gold and silver ores. Small quantities have been found in Utah and Wyoming. It has also been discovered largely in South Australia, whence a quantity of it has been sent into commerce. It is obtained almost entirely from native bismuth, which is heated by means of wood or charcoal, whereby the metal is fused and separated from its gangue. Most of the bismuth of commerce comes from Saxony, although it is now also largely obtained from Bolivia. The bismuth from South America is said to be naturally free from arsenic, and to be therefore preferable for pharmaceutical purposes.

Bismuth was first recognized as a metal by Agricola in 1520. Before that period it was confounded with lead. It is a brittle, pulverizable, brilliant metal, of a crystalline texture, and of a white color with a slight reddish tint. Its crystals are rhombohedral, but with an angle of 87° 40′, which makes it difficult to distinguish them from cubes, in which the angle would be 90°. Indeed, many books still speak of it as cubical in form. It undergoes but a slight tarnish in the air. Its sp. gr. is 9·8, 9·83, *Br.* (purified), melting point 264° C. (507° F.). When impure bismuth solidifies after fusion, globules of the metal, nearly pure, are thrown up from the mass. This takes place when the metal contains as much as 50 per cent. of impurity. The same phenomenon does not occur when pure bismuth is melted. (*R. Schneider.*) At a high temperature, in close vessels, bismuth volatilizes, and may be distilled over. When heated in the open air to a full red heat, it takes fire, and burns with a faint blue flame, forming an oxide of a yellow color. This is the *teroxide*, and consists of two atoms of bismuth and three of oxygen. There is another compound of bismuth and oxygen, consisting of two atoms of the former and five atoms of the latter, which is called *bismuthic oxide*, Bi_2O_5. It is obtained in the form of a hydrate by boiling bismuth nitrate in solution of potassa, washing the precipitate, and mixing it while moist with solution of potassa into which chlorine is passed. A mixture of bismuthous and bismuthic oxides is precipitated, from which the former is separated by digestion with nitric acid. The hydrated oxide remaining, when washed and dried, is in the form of a red powder, which gives up its water at 130° C. (266° F.), and at a higher heat loses oxygen. Bismuth is acted on freely by hydrochloric acid, but violently by nitric acid, which dissolves it with a copious liberation of red fumes. Sulphuric acid, when cold, has no action on it, but at a boiling heat effects its solution with the liberation of sulphurous acid. As it occurs in commerce, it is generally contaminated with other metals, among which are arsenic in minute quantity, traces of silver, cadmium, nickel, lead, and iron, and sometimes a very small proportion of thallium. Classen has found in so-called "purissimus" bismuth, lead, copper, and iron, and in one sample of bismuth, sold as suitable for scientific purposes, he obtained from 500 grammes 10 grammes of lead chloride. (*Apoth. Zeitung*, 1891, p. 121; see, also, *Chem. News*, 1892, lxv. 28.) It may be purified from all contaminating metals by dissolving the bismuth of commerce in diluted nitric acid, precipitating the clear solution by adding it to water, and reducing the white powder thus obtained with black flux. The same precipitate is obtained by adding ammonia to the nitric solution; if the supernatant liquor is blue, the presence of copper is indicated; if the precipitate is yellowish, iron is present. The British Pharmacopœia (1885) contained a process for purifying bismuth which was not introduced in the (1898) edition of the same authority. (See *U. S. D.*, 17th ed., p. 270.)

Pharm. Uses, etc. Bismuth is not used in medicine in an uncombined state, but is employed pharmaceutically to obtain bismuth subcarbonate and subnitrate, the only medicinal preparations formed from this metal. In the arts its oxide is used to form a cosmetic for the complexion, called *pearl white*, and as an ingredient of the best pewter.

BISMUTHI CITRAS. U. S. Bismuth Citrate.

$Bi\ C_6\ H_5\ O_7$; 397·44. (BĬŞ-MŪ'THĪ CĪ'TRĂS.) $Bi\ C_6\ H_5\ O_7$; 399.

Citrate of Bismuth; Bismuthum Citricum; Citrate de Bismuth, *Fr.;* Citronensaures Wismuth, *G.*

"Bismuth Subnitrate, *one hundred grammes* [or 3 ounces av., 230 grains]; Citric Acid, *seventy grammes* [or 2 ounces av., 205 grains]; Distilled Water, *a sufficient quantity.* Boil the Bismuth

Subnitrate and the Citric Acid with *four hundred cubic centimeters* [or 13½ fluidounces] of Distilled Water for about fifteen minutes, or until a drop of the mixture yields a clear solution with ammonia water. Then add *five thousand cubic centimeters* [about 11 pints] of Distilled Water, allow the suspended matter to deposit, wash the precipitate, first by decantation, and afterwards on a strainer, with Distilled Water, until the washings are tasteless, and dry the residue at a gentle heat." *U. S.*

As citric acid ($H_3C_6H_5O_7$) is tribasic, one atom of bismuth, being trivalent, will exactly replace the three hydrogen atoms of the citric acid and form a neutral bismuth citrate. When bismuth subnitrate is boiled with a solution of citric acid it is decomposed, the nitric acid is replaced by the citric acid, and the insoluble bismuth citrate is formed; the completion of the process is known by the mixture yielding a clear solution with ammonia water.

Properties. "A white, amorphous or micro-crystalline powder, odorless and tasteless, and permanent in the air. Insoluble in water or alcohol, but soluble in ammonia water, and in solutions of the citrates of the alkalies. When strongly heated, the salt chars, and, on ignition, leaves a more or less blackened residue having a yellow surface, and soluble in warm nitric acid. This solution, when dropped into water, occasions a white turbidity. A solution of the salt in ammonia water, when treated with hydrogen sulphide in excess, yields a black precipitate. If the filtrate from the latter be deprived by heat of the excess of hydrogen sulphide and cooled, a portion of it, boiled with lime water, yields a white precipitate. If another portion of the cooled filtrate be mixed with an equal volume of concentrated sulphuric acid, and again cooled, no brown or brownish-black color should appear around a crystal of ferrous sulphate dropped into the liquid (limit of *nitrate*)." *U. S.*

Medical Properties. This salt is used solely for pharmaceutical purposes. It is no longer recognized by the British Pharmacopœia.

BISMUTHI ET AMMONII CITRAS. U. S. Bismuth and Ammonium Citrate.

(BĬS-MŪ'THĪ ĔT ĄM-MŌ'NĮ-Ī CĪ'TRĂS.)

Citrate of Bismuth and Ammonium; Citrate de Bismuth et d'Ammoniaque, *Fr.;* Citronensaures Wismuthoxyd-Ammonium, *G.*

"Bismuth Citrate, *one hundred grammes* [or 3 ounces av., 230 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity.* Mix the Bismuth Citrate with *two hundred cubic centimeters* [or 6½ fluidounces] of Distilled Water to a smooth paste, heat the mixture on a water-bath, and gradually add Ammonia Water, until the salt is dissolved, and the liquid is neutral or has only a faintly alkaline reaction. Then filter the solution, evaporate it on a water-bath to a syrupy consistence, and spread it upon plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in small, well-stoppered bottles, protected from light." *U. S.*

The British Pharmacopœia (1898) does not recognize this salt, which has been used quite extensively during the last twenty years, principally for preparing extemporaneously the London Liquor Bismuthi originally suggested by Schacht. (See *Liquor Bismuthi et Ammoniæ Citratis.*)

Properties. "Small, shining, pearly or translucent scales, odorless, having a slightly acidulous and metallic taste, and becoming opaque on exposure to the air. Very soluble in water, and but sparingly soluble in alcohol. When strongly heated, the salt fuses, and finally leaves a more or less blackened residue, having a yellow surface, and soluble in warm nitric acid. This solution, when dropped into water, occasions a white turbidity. The aqueous solution of the salt is neutral or faintly alkaline to litmus paper. When boiled with potassium or sodium hydrate test-solution, it evolves the vapor of ammonia, and when treated with hydrogen sulphide, it yields a black precipitate. If the filtrate from the latter be deprived by heat of the excess of hydrogen sulphide and cooled, a portion of it, boiled with lime water, yields a white precipitate. If another portion of the cooled filtrate be mixed with an equal volume of concentrated sulphuric acid, and again cooled, no brown or brownish-black color should appear around a crystal of ferrous sulphate dropped into the liquid (absence of *nitrate*)." *U. S.* As frequently seen in commerce it is not entirely soluble in water: this is due to the loss of ammonia through exposure, and a few drops of ammonia water added to the turbid solution are generally sufficient to restore its transparency. The Committee of Revision very properly omitted to give its chemical formula, as it is by no means proved that it has a definite composition. It is believed by some to be a true double citrate, $BiC_6H_5O_7(NH_4)_3C_6H_5O_7$. On the other hand, Bartlett (*Zeitsch. für Chem.*, 1865, p. 350) obtained on evaporation of the ammoniacal solution $BiC_6H_5O_7,NH_3 + 3H_2O$, and Rother (*Jahresbericht*, 1876, p. 564) obtained on crystallizing

from warm ammonia $BiC_6H_5O_7,3NH_3 + 3H_2O$. "Ten grains dissolved in water, and treated with sulphuretted hydrogen in excess, yield a precipitate which, when washed and dried, weighs about six and a half grains." *Br.* (1885).

Medical Properties. This salt differs from the older preparations of bismuth in its solubility, and probably is for this reason more rapid, more astringent, and more irritant in its action. In cases of *irritation* or *inflammation* of the *gastro-intestinal mucous membrane* it is very much inferior to the insoluble preparations, but when there is relaxation with excessive discharges it may usefully be employed. The dose is from one to three grains (0·065–0·20 Gm.).

BISMUTHI OXIDUM. Br. Oxide of Bismuth.

Bi_2O_3; 465·68. (BĬṢ-MŪ'THĪ ŎX'Ĭ-DŬM.) **Bi_2O_3; 468.**

"Bismuth Oxide, Bi_2O_3, may be prepared by boiling bismuth oxynitrate with solution of sodium hydroxide." *Br.*

Oxyde de Bismuth, *Fr.*; Bismuthum Oxydatum, Oxydum Bismuthicum; Wismuthoxyd, *G.*

The bismuth subnitrate is decomposed by the solution of soda in this process, bismuth hydrate being formed, which is precipitated, whilst sodium nitrate remains in solution. $2(BiNO_4,H_2O) + 2NaHO = Bi_26HO$ (or $Bi_2O_3,3H_2O$) $+ 2NaNO_3$. At the temperature of 100° C. (212° F.) the bismuth hydrate is decomposed, water is liberated, and the anhydrous oxide is left.

Properties. Bismuth oxide is a powder of a dull lemon-yellow color, insoluble in water, but soluble in nitric acid mixed with half its volume of water without effervescence. The British Pharmacopœia (1898) describes it as "A slightly brownish-yellow powder. It should answer to the general characters and tests enumerated under 'Bismuth Oxycarbonate.' Each gramme should yield 1·1 grammes of bismuth sulphide. Heated to incipient redness it is scarcely diminished in weight (absence of bismuth oxycarbonate, bismuth oxynitrate, and moisture)."

Medical Properties. Bismuth oxide resembles bismuth subnitrate in its medical properties, and may be administered in similar doses.

BISMUTHI SALICYLAS. Br. Bismuth Salicylate.

(BĬṢ-MŪ'THĪ SĂL-Ĭ-CŸ'LĂS.)

"Bismuth Salicylate, or oxysalicylate, $C_6H_4.OH.COO.BiO$, may be prepared by the interaction of bismuth nitrate and sodium salicylate." *Br.*

This salt is a bismuthyl salicylate of definite composition, the bismuth oxide resulting from its ignition being about 64 per cent. Samples which show a higher percentage than this either contain bismuth subnitrate or hydrate. It may be made by Wolff's process, by diluting a glycerin solution of crystallized bismuthous nitrate with one or two parts of water, and decomposing this with a concentrated aqueous solution of sodium salicylate, then washing the precipitate well with hot water and carefully drying. Another method for its preparation will be found in *A. J. P.*, 1891, 401. Fischer and Grützner (*Archiv d. Pharm.*, 1894, 680) object to the variable composition of commercial bismuth salicylate, and recommend the following process for making a basic salt of constant composition. Crystallized bismuth nitrate is dissolved in four times its weight of diluted acetic acid, the solution diluted with about forty times its weight of water, and the bismuth precipitated as hydroxide by ammonia water. The precipitate is washed and mixed with the molecular proportion of salicylic acid. After heating on a water-bath, a magma of crystals of basic bismuth salicylate is formed; these are drained and dried.

The British Pharmacopœia describes this salt as "A white or nearly white amorphous powder, insoluble in *water*. It affords the reactions characteristic of bismuth. Diluted *test-solution of ferric chloride* is colored violet when Bismuth Salicylate is introduced. It should yield only the faintest characteristic reaction with the copper test for nitrates. *Alcohol* (90 per cent.), with which Bismuth Salicylate has been shaken, should not give a violet color with *test-solution of ferric chloride* (absence of free salicylic acid). Decomposed by heating with *solution of sodium carbonate*, the liquid portion of the resulting mixture, if containing not less than 1 per cent. of salicylate, affords a yellowish-brown precipitate on the addition of *solution of uranium nitrate* (distinction from carbolates and sulphocarbolates). Each gramme of Bismuth Salicylate should yield 0·7 gramme of bismuth sulphide. When heated, salicylic acid volatilizes and 62 to 64 per cent. of bismuth oxide remains. It should be free from the impurities indicated under 'Bismuth Oxycarbonate.'"

Medical Properties. Bismuth salicylate was originally proposed as an intestinal antiseptic and feeble astringent, and has been used to a considerable extent in the treatment of chronic *intestinal catarrhs* and subacute *diarrhœas* with marked tendency to intestinal fermentation; also as a local antiseptic remedy for *wounds* and various inflammations of mucous membranes. We have never been able to perceive that it is more effective or different in its action from the older preparations of the metal. It may be given in doses of from ten to twenty grains (0·648 to 1·3 Gm.) every four to eight hours.

BISMUTHI SUBCARBONAS. U. S. (Br.) Bismuth Subcarbonate.

(BĬŞ-MŪ'THĪ SŬB-CĂR'BO-NĂS.)

"Bismuth Oxycarbonate, $(Bi_2O_3CO_3)_2,H_2O$, may be prepared by the interaction of bismuth nitrate and ammonium carbonate." *Br.*

Bismuthi Carbonas, *Br.*, Carbonate of Bismuth; Oxycarbonate of Bismuth; Bismuthum Subcarbonicum, Subcarbonas Bismuthicus; Souscarbonate de Bismuth, *Fr.*; Basisches Kohlensaures Wismuthoxyd, *G.*

A process for this salt is no longer official; that of the Pharm. 1870 will be found in the foot-note below.*

This preparation was first made official in the 1860 edition of the U. S. Pharmacopœia. As metallic bismuth generally contains arsenic, it is very important to provide that this should be left behind, in the processes for making its medicinal preparations. It is on this account that the formula of the U. S. Pharm. 1870 was so elaborate. The bismuth is first dissolved in nitric acid, a portion of which oxidizes the metal, with the evolution of nitrous vapors, while another portion combines with the oxide produced to form bismuth nitrate. At the same time the arsenic is also oxidized at the expense of the nitric acid, and unites with a portion of the oxidized metal so as to produce bismuth arsenate. Both of these salts, therefore, are contained in the solution, which is very concentrated. Both have the property, when their solution is diluted with water, of separating into two salts, one an insoluble subsalt which is deposited, and the other a soluble acid salt which is held in solution. But the arsenate is more disposed to the change than the nitrate, and requires for the purpose a smaller amount of water of dilution. Hence the first direction, after the metal has been dissolved, is to add a moderate quantity of distilled water, insufficient to cause the decomposition of the nitrate. From this diluted solution the insoluble subarsenate is slowly deposited, so as, in the course of twenty-four hours, to free it almost if not entirely from the poisonous metal. This is separated by filtration, and the solution is now diluted with a much larger quantity of distilled water, which causes a copious deposition of bismuth subnitrate. But, in order not to waste the acid nitrate remaining in solution, this is decomposed by ammonia, which takes most of the nitric acid, and precipitates the bismuth combined with the remainder, in the form of subnitrate. The whole of the precipitated subnitrate, thus freed from arsenic, is redissolved in nitric acid, and the solution of the nitrate now obtained, being diluted with just so much water as to produce a commencing precipitation of subnitrate, is freed by filtering from the small quantity formed, and slowly added to a solution of sodium carbonate. An interchange takes place; sodium nitrate and bismuth carbonate are formed, the former of which remains in solution, and the latter is deposited. This part of the process tends still further to get rid of the arsenic; for if any of the arsenic acid or bismuth arsenate existed in the solution the poisonous acid would combine with the soda, and, thus forming a soluble salt, would be retained by the water. Nothing now remains but to wash, dry, and powder the precipitate.

The British (1885) process (see *U. S. D.*, 17th ed., p. 265) is more simple, because, using bismuth already purified, it is without the preliminary measures taken in the U. S. process to separate the arsenic.

* "Take of Bismuth, in pieces, *two troyounces;* Nitric Acid *eight troyounces and a half;* Water of Ammonia *five fluidounces;* Carbonate of Sodium *ten troyounces;* Distilled Water *a sufficient quantity.* Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled Water in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, after twenty-four hours, filter through paper. To the filtered liquid, previously diluted with an equal measure of Distilled Water, slowly add the Water of Ammonia, constantly stirring. Transfer the whole to a strainer, and after the precipitate has been drained, wash it with two pints of Distilled Water, and drain it again. Then place the precipitate in a proper vessel, add the remainder of the Nitric Acid, and afterwards four fluidounces of Distilled Water, and set the solution aside. At the end of twenty-four hours, filter through paper. Dissolve the Carbonate of Sodium in twelve fluidounces of Distilled Water, with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless. Lastly, press, dry it on bibulous paper with a gentle heat, and rub it into powder." *U. S.* 1870.

Properties. Bismuth subcarbonate is "a white or pale yellowish-white powder, of somewhat varying chemical composition,* odorless and tasteless, and permanent in the air. Insoluble in water or alcohol, but completely soluble in nitric or hydrochloric acid, with copious effervescence. When heated to redness, the salt loses water and carbon dioxide, and leaves from 87 to 91 per cent. of a yellow residue which is soluble in nitric or hydrochloric acid, and blackened by hydrogen sulphide." *U. S.* Its sp. gr. is about 4. It effervesces with acids, and, when exposed to heat, loses 9·5 per cent. of its weight (*U. S.* 1870) in consequence of the escape of carbonic acid, and is converted into the anhydrous teroxide, of a light yellow color. When mixed with sulphuric acid, and subjected to Marsh's test, it should yield no arsenic, or merely a trace.

Tests. "If 3 Gm. of the salt be dissolved in just a sufficient quantity (about 4 C.c.) of warm nitric acid, and the solution poured into 100 C.c. of water, a white precipitate is produced. After filtering, and evaporating the filtrate on a water-bath to 30 C.c., again filtering, and dividing this filtrate into portions of 5 C.c., these should respond to the following tests: On mixing one portion with an equal volume of diluted sulphuric acid, it should not become cloudy (absence of *lead*.) If another portion be precipitated with a slight excess of ammonia water, the supernatant liquid should not exhibit a bluish tint (absence of *copper*). Other portions should not be affected by silver nitrate test-solution (absence of *chloride*), or barium nitrate test-solution (*sulphate*), nor yield, with hydrochloric acid, a precipitate which is insoluble in a slight excess of the latter (*silver*). If 1 Gm. of the salt be boiled with 10 C.c. of a mixture of equal parts of acetic acid and water, the solution cooled and filtered, and the filtrate freed from bismuth by hydrogen sulphide and again filtered, the last filtrate should leave no residue on evaporation (absence of *alkalies* and *alkaline earths*). On boiling 1 Gm. of the salt with 10 C.c. of potassium or sodium hydrate test-solution, it should not evolve the odor of *ammonia*. If 1 Gm. of the salt be added to 10 C.c. of a mixture of equal parts of concentrated sulphuric acid and water, tinged slightly blue with indigo test-solution, on heating, the bluish tint should not be discharged (absence of *nitrate*). If 1 Gm. of the salt be ignited in a porcelain crucible, the residue, when cold, dissolved in 5 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), no dark coloration or precipitate should be produced within fifteen minutes (limit of *arsenic*)." *U. S.* The British Pharmacopœia describes it as follows: "A whitish powder, the general chemical characters and reactions of which are similar to those of Bismuth Oxide and Bismuth Oxynitrate. All three compounds are heavy powders insoluble in *water*, but soluble in *nitric acid* diluted with half its bulk of *water*. Each yields the reactions characteristic of bismuth. When either is dissolved in a little *hydrochloric acid*, the solution diluted with *water* slightly acidulated with the same acid, and then excess of *hydrogen sulphide* passed through the liquid, a brownish-black precipitate of bismuth sulphide falls. This precipitate, when rapidly washed on a counterpoised filter with *water*, and quickly dried at 212° F. (100° C.), serves for the estimation of the amount of bismuth present in the compound. These bismuth salts, when suitably treated, should yield no characteristic reaction with the tests for silver, lead, copper, arsenium, iron, zinc, calcium, magnesium, chlorides, or sulphates, nor with the tests for selenium or tellurium. Bismuth Oxycarbonate affords the reactions characteristic of carbonates, but not more than the slightest reactions with the tests for nitrates. Each gramme of it should yield 0·99 gramme of bismuth sulphide when treated as described above." If arsenic were present, a precipitate would take place with a much smaller proportion of water.

Medical Properties and Uses. This salt was brought into notice by M. Hannon, of Brussels (*Ann. de Thérap.*, 1857, 214), on the ground that it was more tonic than the subnitrate; it is, however, exactly equivalent to the latter salt in therapeutic action and dose.

BISMUTHI SUBNITRAS. U. S., Br. Bismuth Subnitrate. Bismuth Oxynitrate.

(BĬŞ-MŪ'THĪ SŬB-NĪ'TRĂS.)

"Bismuth Oxynitrate, $BiONO_3,H_2O$, is prepared by the interaction of bismuth nitrate and water." *Br.*

Subnitrate of Bismuth; Bismuthum Album, *Br.* 1864; White Bismuth; Bismuthum subnitricum, *P.G.*; Bismuthum Hydrico-nitricum, Magisterium Bismuthi, Subazotas (s. Subnitras) Bismuthicus; Sous-azotate de Bismuth, *Fr.*; Basisches Salpetersaures Wismuthoxyd, *G.*; Oxynitrate of Bismuth.

* The British Pharmacopœia gives the following chemical formula: $(Bi_2O_2CO_3)_2H_2O$.

A process for bismuth subnitrate is no longer official in the U. S. or Br. Pharmacopœia. The process of the U. S. P. (1870) is given in the foot-note.*

The alterations from the old process in the U. S. P. formula of 1870 were based upon the wish to get rid of any arsenic that might be present in the bismuth used. This is accomplished by first preparing the carbonate, by adding the nitric acid solution of bismuth to a solution of sodium carbonate in excess, whereby most of the arsenic is retained in the solution, probably as sodium arsenate, while the insoluble carbonate is precipitated. This is dissolved, with the aid of heat, in nitric acid, so as to make a very concentrated solution of the nitrate, to which, when cold, just so much water is added as to begin to produce a permanent turbidity. The object of this is to allow any arsenic that may be still present to be deposited, which happens for reasons stated in explaining the process for procuring the subcarbonate. (See page 271.) The deposited matter having been precipitated, only the pure nitrate remains in solution, which is made to yield the subnitrate by large dilution with water, and still more completely by the addition of ammonia.

In the British formula, the old method is pursued of simply dissolving the bismuth, which has been previously purified, in nitric acid somewhat diluted, concentrating the solution, and precipitating by adding it to a large quantity of water. When bismuth is added to dilute nitric acid, red fumes are copiously given off, and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder so as to form a solution of bismuth ternitrate. It is unnecessary to have the metal in powder, as it dissolves with great facility when added to the acid in fragments. When the solution is completed, the liquor should be added to the water, and not the water to the solution. In order to have a smooth light powder, which is most esteemed, the precipitate should be well washed to remove every trace of free nitric acid, and dried as speedily as possible. In the use of this formula it is taken for granted that the bismuth has been ascertained to be free from arsenic; and if it prove upon the application of Marsh's test to be otherwise, means should certainly be employed to purify it before using it. Measures for this purpose are mentioned under *Bismuthum.* Should the subnitrate or subcarbonate be ascertained to contain arsenic, it may, as suggested by Dr. Herapath, be purified by boiling it with solution of caustic soda or potassa twice successively, then thoroughly washing the residue, which will be yellow oxide of bismuth, dissolving it again in nitric acid, and precipitating by water as before. (*Chem. News*, 1863, p. 77.) In the washing of bismuth subnitrate, the salt is asserted to lose a portion of its nitric acid; and the change may be considerable, if the washing be continued so long as the liquid comes away in any degree acidulous. It has been ascertained by Julius Löwe that this effect may be avoided by washing with a very dilute solution of ammonium nitrate, containing one part in 500 parts of water. (*Chem. Gaz.*, March 15, 1859, 119.)† *Bismuthous nitrate*, a crystalline salt ($Bi3NO_3.5H_2O$), is deposited from a solution of bismuth in nitric acid. This has been used by Dr. Balmanno

* Take of Bismuth, in pieces, *two troyounces;* Nitric Acid *eight troyounces and a half;* Carbonate of Sodium *ten troyounces;* Water of Ammonia *five fluidounces;* Distilled Water *a sufficient quantity.* Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled Water, in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, after twenty-four hours, filter through paper. Dissolve the Carbonate of Sodium in twenty fluidounces of Distilled Water with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless, and drain again as completely as possible. Then place the moist precipitate in a capacious vessel, gradually add the remainder of the Nitric Acid, and afterwards four fluidounces of Distilled Water, and set the solution aside. At the end of twenty-four hours, filter through paper, and to the filtered liquid, previously diluted with four pints of Distilled Water, slowly add the Water of Ammonia, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with two pints of Distilled Water, drain it again, and press out as much of the liquid as possible. Lastly, dry it upon bibulous paper with a gentle heat, and rub into powder." *U. S.* 1870.

† In order to avoid the handling of large volumes of liquid, as well as the loss of bismuth by the production of soluble salts, A. Lalieu proposes the following process, which, he says, yields a much larger, purer, and denser product: 200 grammes of bismuth are dissolved in a sufficient quantity of nitric acid; the clear solution is decanted and poured into about 8 liters of water containing 500 grammes of water of ammonia. The precipitate is washed, transferred to a capsule, and 50 to 60 grammes of caustic soda, dissolved in a little water, are added to it. The capsule is then exposed for 15 to 20 minutes to the heat of a water-bath, and the contents stirred up several times. After having again become cold, the supernatant liquor is poured off, the precipitate is thoroughly washed, and a quantity of nitric acid, representing 48·5 grammes of anhydrous nitric acid (to be determined from the sp. gr., etc.), is added to it in small portions at a time, and under constant stirring. If, during this addition, the mass should become too thick, a little water may be added, but not enough to destroy the pasty consistence of the mass. The capsule is then replaced for a few minutes on the water-bath, and the mass well stirred. The latter, which had been yellow, becomes soon perfectly white, and somewhat more liquid. It is then diluted with a little water, the precipitate collected on a filter placed on a muslin strainer, washed, drained, pressed, and dried. The product amounts to about 265 grammes. (*L'Union Pharmaceutique*, No. 8; *N. R.*, Nov. 1878.)

Squire dissolved in glycerin, under the name of *Glycerole of Nitrate of Bismuth.* (*P. J. Tr.*, Nov. 11, 1876.) W. W. Moorhead prepares it by taking two troyounces of crystalline bismuth nitrate and dissolving in sufficient glycerin to make eight fluidounces. No heat should be used. This preparation can be diluted with an equal bulk or less of water, or one part can be added to forty-eight of water without ready precipitation, but one part to twelve, eight, or six of water soon precipitates. (*A. J. P.*, 1877, p. 98; also pp. 23 and 89.)

Properties. Bismuth subnitrate is "a heavy, white powder, of somewhat varying chemical composition,* odorless and almost tasteless, and permanent in the air. Almost insoluble in water, and insoluble in alcohol; but readily soluble in nitric or hydrochloric acid. When heated to 120° C. (248° F.), the salt loses water (between 3 and 5 per cent. of its weight); and when subsequently heated to redness, it evolves nitrous vapors, leaving from 79 to 82 per cent. of its weight of a yellow residue which is soluble in nitric or hydrochloric acid, and blackened by hydrogen sulphide. When brought upon moistened blue litmus paper, the salt shows a slightly acid reaction. On dissolving 3 Gm. of the salt in 3 C.c. of warm nitric acid, no effervescence should occur (absence of *carbonate*), and no residue should be left (absence of *insoluble foreign salts*). If this solution be poured into 100 C.c. of water, a white precipitate is produced. If the filtrate separated from this precipitate be evaporated on a water-bath to 30 C.c., the liquid again filtered, and the new filtrate divided into portions of 5 C.c. each, these should respond to the tests for purity described under *Bismuthi Subcarbonas.* When further tested as described under *Bismuthi Subcarbonas*, the salt should be found free from *alkalies* and *alkaline earths*, and should give no reaction for *ammonia.* If 1 Gm. of the salt be heated, in a porcelain crucible, until nitrous vapors cease to be evolved, the residue, when cold, dissolved in 5 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), no dark coloration or precipitate should be produced within fifteen minutes (limit of *arsenic*)." *U. S.* The British Pharmacopœia describes it as "A heavy white inodorous powder consisting of minute crystalline scales, with not more than a slight action on *litmus.* It should answer to the general characters and tests enumerated under 'Bismuth Oxycarbonate.' Each gramme should yield 0·84 gramme of bismuth sulphide. It should afford only the slightest reactions with the tests for carbonates. If 1 gramme be dissolved in *nitric acid* and the liquid mixed with a solution of about 2 grammes of *citric acid* and sufficient *solution of ammonia* to give decided alkalinity, no precipitate or opalescence should be produced by boiling the mixture while still faintly alkaline (absence of calcium phosphate)." It is readily soluble in the strong acids, from which it is precipitated by water. The fixed alkalies dissolve it sparingly, and ammonia more readily. It is darkened by hydrogen sulphide gas, but not by exposure to light, unless it contains a little silver, or is subjected to the influence of organic matter. If the nitric solution is not precipitated by dilute sulphuric acid, it is free from lead. It sometimes contains arsenic, which may be detected by acting on it with pure sulphuric acid, evaporating to dryness, dissolving in hot distilled water, and testing a part of the solution by Marsh's apparatus. By this method M. Lassaigne detected one-sixth of 1 per cent. of arsenic in a sample of subnitrate sold in Paris. M. Glénard proposes two new methods of searching for arsenic in the subnitrate; one merely qualitative, the other quantitative. The first consists in strongly heating a mixture of the suspected salt with potassium acetate. The least trace of arsenic will be detected by the strong and offensive odor produced, owing to the formation of cacodyl. In the second, the bismuth subnitrate is heated with pure hydrochloric acid. If arsenic be present it will rise in vapors in the form of chloride. These should be carefully collected and condensed, and then treated with an excess of hydrogen sulphide. The arsenic sulphide precipitated will be the measure of the metal. (*Ann. de Thérap.*, 1868, p. 176.) M. Lassaigne has found as much as 27 per cent. of bismuth chloride in this preparation, when obtained by precipitating, with water, a solution of bismuth in a mixture of nitric and hydrochloric acids. The same impurity is introduced, to a small extent, by using common water containing chlorides; and bismuth subsulphate renders the preparation impure, when the water used contains calcium sulphate. (*Journ. de Chim. et Méd.*, 1855, p. 276.) These facts show the necessity of using distilled water. As regards the origin of the chlorine sometimes existing in commercial bismuth subnitrate, it is asserted by Mr. R. C. Tichborne to be a common practice with the manufacturer, in order to save the bismuth existing in the mother-liquor, after the deposition of the subnitrate, to precipitate it with sodium chloride, thus obtaining an insoluble bismuth oxychloride, which is then added to the previous product. (*P. J. Tr.*, 1860, 413.) For

* The British Pharmacopœia gives the following chemical composition: $BiONO_3,H_2O$.

the modes of detecting and separating it, the reader is referred to the *Chemical News* (1863, p. 109). The metal thallium is said to be present in most specimens of the pharmaceutical preparations of bismuth, whilst the fetid odor of the breath so often produced when the subnitrate is administered is believed to be due to traces of tellurium. (Brownen, *P. J. Tr.*, Oct. 16, 1875.) It has also been said that the arsenic usually present in minute quantities is the cause of the garlicky odor of the breath. Dr. E. R. Squibb (*Ephemeris*, Sept. 1882) states, however, that the "bismuth breath" has been noticed in patients who were taking a preparation of bismuth in which the absence of both tellurium and arsenic was conclusively shown. The cause of the peculiar odor is, therefore, at present doubtful. Calcium phosphate has been ascertained to be an occasional adulteration of the subnitrate. A ready method of detecting it suggested by M. Roussin has proved to be fallacious, and may lead to false decisions as to the presence of the phosphate. There can be no difficulty in detecting the adulteration by the U. S. P. tests. Bismuth subnitrate was called by the earlier chemists *magistery of bismuth*. It is incompatible with potassium iodide (slowly forming a brick-red bismuth iodide) and with alkaline bicarbonates. For examination of commercial bismuth subnitrate by Prof. Curtman, see *A. J. P.*, 1896, 422, and *Pharm. Era*, 1896, 43.

Medical Properties. The great insolubility of bismuth subnitrate has led to the belief that it is not absorbed in the gastro-intestinal tract, but the finding of it by Orfila in the spleen and liver, by Lewald in the milk, by Bergeret and Mayençon and other chemists in the urine, proves that the slow absorption of the drug does take place. The largest doses, however, given internally, never produce any general sensible effect upon the system, the remedy being employed solely for its soothing, sedative, feeble astringent influence upon mucous membranes. It is very useful in *subacute gastritis*, *gastralgia*, *pyrosis*, and allied *stomachic disease*, in which affections it should be given before or just after meals; when given one to two hours after meals, the subnitrate escapes with the contents of the stomach into the intestines, and is very useful in conditions of *irritation of the intestinal mucous membranes*. It may be employed in *diarrhœas of irritation*, and even in *dysentery*, but in *diarrhœas of relaxation* it is of little service. Its use produces dark-green or blackish discoloration of the stools. Bismuth subnitrate is also a very useful topical application in various mucous inflammations, other than gastro-intestinal; thus, it is used with advantage by injection (gr. v–xx to f ʒi of mucilage) in the first stage of *gonorrhœa*, in *leucorrhœa*, in *dysentery*, and in *rectal irritation*, and by snuffing in *coryza*, etc. The dose of bismuth subnitrate is from five to forty grains (0·324 to 2·6 Gm.), three or more times a day; the large dose being employed in *diarrhœa*. Even in much larger amounts than those mentioned the medicine is practically safe; the symptoms described by Orfila and other early toxicologists as produced by it having been undoubtedly due to irritant impurities which formerly existed in the drug.

As has been shown by Theodore Kocher, even the insoluble preparations of bismuth are active antiseptics, and they were for a time much used in Germany in the treatment of *wounds*. It was claimed for them that they acted like iodoform and were not capable of producing poisonous symptoms. Further experience has shown, however, that this is incorrect; that when applied in large quantities to extensive wounded surfaces they are capable of yielding so much bismuth to absorption as to produce a poisoning, which is characterized by acute stomatitis, with a peculiar black discoloration of the mucous membrane, usually beginning upon the borders of the teeth, but spreading over the whole mouth, followed by an intestinal catarrh, with pain and diarrhœa: in severe cases desquamative nephritis, as shown by albuminous urine and epithelial tube-casts, may also occur.

BROMUM. U. S. Bromine.

Br; 79·76. (BRŌ′MŬM.) Br; 79·8.

Brominium, *U. S.* 1870; Bromum, *P. G.*; Brome, *Fr.*; Brom, *G.*; Bromo, *It.*

Bromine is an elementary body, possessing many analogies to chlorine and iodine. It was discovered in 1826 by M. Balard, of Montpellier, in the bittern of sea-salt works, in which it exists as a magnesium bromide. Since then it has been found in the waters of the ocean, in certain marine animals and vegetables, in various aquatic plants, as the water-cress, in numerous salt springs, and in the mineral kingdom. It has also been detected by M. Mène in the coal-gas liquor of the Paris gas works. In the United States it was first obtained by Professor Silliman, who found it in the bittern of the salt works at Salina, in the State of New York. It was discovered in the salt wells near Freeport, Pa., by Dr. David Alter, and is now obtained in largest amount from the brines of Ohio, Pennsylvania, and West Virginia. The

chief works are located at Parkersburg and Mason City, W. Va., Pomeroy, Ohio, and Midland County, Mich. The annual production of bromine in the United States for the last few years has been as follows: 1895, 394,854 lbs., valued at $102,662; 1896, 550,285 lbs., valued at $143,074; and 1897, 487,149 lbs., valued at $136,402. Of the output in the last-mentioned year, 132,200 lbs. were in the form of potassium bromide. The bromides contained in the mother-liquors of the salt wells are oxidized by manganese dioxide in West Virginia and Ohio, while potassium chlorate is the favorite oxidizing agent in Michigan, because of the large proportion of calcium chloride in the liquor.

Preparation. The original salt-liquor or brine is pumped out of the ground at 9° B., evaporated to about 15° in large iron pans, then allowed to settle, and is further evaporated in wooden tanks heated by steam pipes to the point of crystallization. These tanks, five in number, are placed at different elevations, one above the other. Each day the liquor is run off from No. 1, the highest, to No. 2, next day to No. 3, and so on until it reaches No. 5, the crystallized salt being removed from each tank after draining off the liquor. The brine which reaches No. 5 is bittern, and consists chiefly of calcium, magnesium, sodium, and some aluminum chlorides, with varying percentages of sodium and calcium bromides.

The bittern marking 30° to 38° B. is evaporated to about 45° B. By this further evaporation an additional percentage of impure salt is removed, the liquor is then run into stone stills, materials for generation of chlorine added, and heat applied by means of steam until the bromine has been all eliminated and vaporized. It is condensed and collected in cooled receivers. (*Proc. A. P. A.*, 1877, p. 448.) An improved bromine still is figured in *N. R.*, April, 1877; see also *N. R.*, 1883, 108; *Amer. Drug.*, 1884, 121. The chief source of the bromine abroad is at Stassfurt in Germany, where the magnesium bromide remains as a residue in the working of the potassium salts. The bromine is extracted from the solution of bromide in a continuous process by the joint action of chlorine gas and steam.

Bromine has also been obtained from sea-weeds by carbonizing them, lixiviating the carbonaceous residue, and then separating the ingredients, among which are iodine and bromine. For details, see *Chem. News* (July 6, 1866, p. 2). More than two-thirds of the bromine of commerce is used for the manufacture of bromides for medicinal use, and for photography; the remainder is used for aniline colors.

Properties. Bromine is a volatile liquid, of a dark red color when viewed in mass, but hyacinth-red in thin layers. Its taste is very caustic, and its smell intensely strong and disagreeable, having some resemblance to that of chlorine.* Its sp. gr. is very nearly 3 (2·99, *U. S.*, 2·97 to 3·14, *Br.* (1885). At —24·5° C. (—12° F., Baumhauer,† —7·2° C., Philipp) it becomes a hard, brittle, crystalline solid, having a dark leaden color, and a lustre nearly metallic. It boils at about 63° C. (145·4° F.), forming a reddish vapor resembling that of nitrous acid, and of the sp. gr. 5·54. It evaporates readily, a single drop being sufficient to fill a large flask with its peculiar vapor.

Bromine is sparingly soluble in water (in 30 parts at 15° C. (59° F.), *U. S.*), to which it communicates an orange color, more soluble in alcohol, and still more so in ether, chloroform, and carbon disulphide. By the aid, however, of potassium bromide, it may be dissolved to any desirable extent in water. Its alcoholic and ethereal solutions lose their color in a few days, and become acid from the generation of hydrobromic acid. It bleaches vegetable substances like chlorine, destroys the color of indigo sulphate, and decomposes organic matters. Its combination with starch has a yellow color. It corrodes the skin and gives it a deep yellow stain. Bromine is intermediate in its affinities between chlorine and iodine, since its combinations are decomposed by chlorine, while, in its turn, it decomposes those of iodine. It forms acids which are analogous in properties and composition to the corresponding acids of chlorine and iodine. It combines also with chlorine, forming bromine chloride, which probably has the formula $BrCl_3$. This is prepared by passing chlorine through bromine, and condensing the vapors at a low temperature. It is a reddish-yellow liquid, very volatile, soluble in water, with a penetrating odor and disagreeable taste.

Commercial bromine sometimes contains as much as 6 or 8 per cent. of *carbon tetrabromide*, as ascertained by M. Poselger. He discovered the impurity by submitting some bromine to distillation, during the progress of which the boiling point rose to 120° C. (248° F.). The

* Inhaled in the form of vapor it produces great irritation, and endangers asphyxia through spasm of the glottis. A case which had nearly proved fatal was apparently saved by throwing steam sufficiently cooled into the larynx. (G. P. Duffield, *A. J. P.*, 1868, p. 288.)

† See *A. J. P.*, Oct. 1872, p. 452. The higher degree usually given in chemical works is ascribed by Baumhauer to the presence of water in the bromine examined.

residuary liquid at this temperature was colorless, and when freed from a little bromine, proved to be carbon bromide, as an oily, aromatic liquid.* Chlorine and iodine are frequently found in bromine, the former being more common in American and the latter in German bromine.

The U. S. P. gives the following tests for determining the purity of bromine. "If Bromine be added to an excess of potassium or sodium hydrate test-solution, it should combine to form a permanently clear liquid, without the separation of oily drops, or the development of an odor resembling that of chloroform (absence of *bromoform* or *other organic bromine compounds*). If an aqueous solution of Bromine be shaken with a slight excess of reduced iron until it becomes nearly colorless, the filtered liquid, on the addition of a small amount of ferric chloride and of starch test-solution, should not assume a blue color (absence of *iodine*). If 1 C.c. of a saturated aqueous solution of Bromine be diluted with 9 C.c. of water, then mixed with 3 C.c. of ammonium carbonate test-solution, and 5 C.c. of silver nitrate decinormal volumetric solution, and the whole actively shaken, the filtered liquid, when supersaturated with nitric acid, should not become more than opalescent, nor separate a flocculent precipitate within three minutes (absence of more than 3 per cent. of *chlorine*); on exposure to air or heat it is completely volatilized." *U. S.*

In testing for bromine in mineral or saline waters, the water is evaporated in order to crystallize most of the salts. The solution, after having been filtered, is placed in a narrow tube, and a few drops of strong chlorine water are added. If this addition produce an orange color, bromine is present. The water examined, in order that the test may succeed, must be free from organic matter, and the chlorine not be added in excess. Bromine may be detected in marine vegetables by carbonizing them in a covered crucible, exhausting the charcoal, previously pulverized, with boiling distilled water, precipitating any alkaline sulphide present in the solution by zinc sulphate, and then adding successively a few drops of nitric acid and a portion of ether, shaking the whole together. If bromine be present it will be set free and dissolve in the ether, to which it will communicate an orange color. (*Dupasquier.*) According to Reynoso, a more delicate test is furnished by hydrogen peroxide, which liberates bromine from its compounds without reacting on it when free. The mode of proceeding is as follows. Put a piece of barium peroxide in a test-tube, and add successively distilled water, pure hydrochloric acid, and ether. The materials are here present for generating hydrogen peroxide; and so soon as bubbles are seen to rise to the surface, the substance suspected to contain bromine is added, and the whole shaken together. If a bromide be present, the hydrochloric acid will give rise to hydrobromic acid; and the hydrogen peroxide, acting on this, will set free the bromine, which will dissolve in the ether, and give it a yellow tint and the odor of bromine.

Medical Properties. Bromine, from its analogy to iodine, was early tried as a remedy. It has been asserted that it acts like iodine as an alterative, and as a stimulant to the lymphatic system. It has been employed in *bronchocele*, *scrofulous tumors* and *ulcers*, *secondary* and *tertiary syphilis*, *amenorrhœa*, *diphtheritic affections*, *chronic diseases of the skin*, and *hypertrophy of the ventricles*. Magendie recommends it in cases in which iodine does not operate with sufficient activity or has lost its effect by habit, but at present it is very rarely used. About six drops (0·36 C.c.) of an aqueous solution containing one part of bromine to forty of distilled water may be taken several times a day in water. Locally in its concentrated state it is a very powerful and deep caustic. When used as a wash for *ulcers*, from ten to forty minims may be added to a pint of water. The use of bromine as a caustic in *hospital gangrene* was proposed by Dr. Goldsmith during the war of the rebellion, and became universal in the army hospitals. Applied pure by means of a glass rod, it destroyed the diseased tissues more rapidly and thoroughly than did even strong nitric acid. Of the compounds of bromine, the potassium, ammonium, iron, and mercury bromides have been chiefly used. Some of them have been found to exercise a remarkable influence in allaying *nervous irritation*, and are now much employed for that purpose. See these titles respectively in the different parts of this work.† *Bro-*

* It is stated by T. L. Phipson that he has found in commercial bromine, accounted pure, a notable amount of cyanogen, and that it may be detected as follows. Take of iron filings and bromine, of each, half an ounce; add to the filings 2 or 2·5 ounces of water; introduce the bromine very gradually, stirring steadily; filter rapidly while warm from the reaction; and put the filtered liquid in a partially closed bottle. In the course of some hours a deposit of iron ferricyanide (Berlin blue) will have formed, and may be collected on a filter. In the course of two days the whole of the cyanogen will be deposited. In the samples of bromine thus examined he had found from 0·5 to 1 per cent. of cyanogen. (*Chem. News*, 1873, p. 51.)

† *Iodine bromide* in aqueous solution is sometimes employed, which is made by rubbing 10 parts of iodine with 46 parts of distilled water, introducing into a flask, adding 20 parts of bromine, and shaking until the iodine is dissolved. 530 parts of distilled water are added, and the whole filtered. 20 parts contain 1 part of iodine terbromide. A solution containing 15 per cent. is sometimes found in commerce.

mine chloride has been used in *cancer* by Landolfi, of Naples, both externally as a caustic and internally. But a committee of the French Academy reported decidedly against it.

Dr. J. Lawrence Smith, of Louisville, Ky., proposes the following as a convenient formula for a solution of bromine. Dissolve 160 grains of potassium bromide in two fluidounces of water, add one troyounce of bromine, and, stirring diligently, pour in sufficient water to make the solution measure four fluidounces. The solution should be kept in accurately stopped bottles. This is a suitable preparation for application to hospital gangrene, and may be diluted to any desirable extent with water. (*A. J. P.*, 1863, p. 202.)

Bromine, in an overdose, acts as a corrosive poison. A case of poisoning by this substance, which proved fatal in seven hours and a half, is related by Dr. J. R. Snell. The amount swallowed was about an ounce, and the symptoms generally were those produced by the irritant poisons: such as violent inflammation of the lips, mouth, tongue, and œsophagus, with incessant burning pain, followed, in two hours and a half, by prostration, ending in death. (*New York Journ. of Med.*, Sept. 1850.) The best antidote, according to Mr. Alfred Smee, is ammonia, given largely diluted and mixed with sweet oil.

Bromine is extensively used in tho manufacture of bromides, in photography, and in the manufacture of coal-tar colors.

BRYONIA. U.S. Bryonia. [Bryony.]

(BRĪ-Ō'NI-Ą.)

"The root of Bryonia alba, and of Bryonia dioica Linné (nat. ord. Cucurbitaceæ)." *U. S.*

Bryone couleuvrée, *Fr.*; Zaunrübe, Gichtrübe, *G.*

Bryonia alba, or white bryony, is a perennial, climbing, herbaceous plant, growing in thickets and hedges in different parts of Europe. It bears rough, heart-shaped, five-lobed leaves, small yellow monœcious flowers, arranged in racemes, and roundish black berries about the size of a pea. Another species, called *B. dioica*, with diœcious flowers and red berries, bears so close a resemblance in character and properties to the preceding that it is considered by some botanists merely a variety. The roots of both plants are gathered for use. When fresh they are spindle-shaped, sometimes branched, a foot or two in length, as thick as the arm, or even thicker, externally yellowish gray and circularly wrinkled, within white, succulent, and fleshy, of a nauseous odor, which is lost in great measure by drying, and of a bitter, acrid, very disagreeable taste. The peasants are said sometimes to hollow out the top of the root, and to employ the juice which collects in the cavity as a drastic purge. (*Mérat and De Lens.*) The berries are also purgative, and are used in dyeing. *B. americana*, Lam., and *B. africana*, Thunb., are respectively used in the West Indies and Africa as hydragogue cathartics in dropsy. The berries of the European *Black Bryony*, *Tamus communis*, are said to be an irritant poison, and M. Coutagne has found that their tincture causes in animals paralysis and convulsions. (*Rép. de Pharm.*, Nov. 1884.)

Properties. As kept in the shops, the root is in circular transverse slices, externally yellowish gray and longitudinally wrinkled, internally of a whitish color, becoming darker by age, concentrically striated, light, brittle, and readily pulverizable, yielding a whitish powder. It is officially described as follows. "In transverse sections about 5 Cm. in diameter, the bark gray-brown, rough, thin, the central portion whitish or grayish, with numerous, small, projecting wood-bundles arranged in circles and radiating lines; fracture short; inodorous; taste disagreeably bitter." *U. S.* Besides a peculiar glucoside called *bryonin*, the root contains a resin, to which the name of *bryoresin* has been given. It yields its active properties to water. *Bryonin*, $C_{34}H_{48}O_9$, may be obtained by exhausting the coarsely pulverized root in the cold with water containing 3 per cent. of hydrochloric acid. This acid aqueous liquid is then treated with tannin until no further precipitate occurs, the precipitate treated first with water containing HCl and then with distilled water, dried, pulverized, and dissolved in 90 per cent. alcohol; the solution is filtered, decomposed with zinc oxide, and the resulting mass exhausted with cold distilled water. This on evaporation yields impure bryonin, which is purified by dissolving it in water containing hydrochloric acid and dialyzing it. It is white, amorphous, very bitter, soluble in water and alcohol, insoluble in ether and chloroform. It is dextrogyre and precipitates tannin and ammoniacal lead acetate. The root thus exhausted with water and dried, when treated with 90 per cent. alcohol, yields the *bryoresin*. This is soft at 15° C., red, amorphous, soluble in alcohol, ether, chloroform, glacial acetic acid, and alkalies. Bryonin, boiled with dilute sulphuric acid, yields a glucose and a yellowish, amorphous resin, *bryogenin*. This latter is soluble in alcohol, insoluble in ether.

(Masson, *Journ. de Pharm. et de Chim.*, 1893, 300; see also report of investigation by C. F. Heller, *A. J. P.*, 1887, 68.)

Medical Properties. Bryony is an active hydragogue cathartic, in large doses sometimes emetic, and disposed, if too largely administered, to occasion inflammation of the alimentary mucous membrane. It appears also to have direct relations with the nervous system, and it has in a number of cases produced serious or even fatal poisoning. Vomiting and purging have been commonly present, but in some cases there has been no diarrhœa. Giddiness, delirium, and dilated pupils, coupled with fall of the bodily temperature, imperceptible pulse, cold perspiration, and other manifestations of collapse, are the usual symptoms. Eighty minims of the homœopathic tincture caused very serious but not fatal poisoning. (For cases see *P. J. Tr.*, 1858, p. 542; *Lancet*, May 9, 1868; *Brit. Med. Journ.*, 1883, ii. 1067; *Ther. Gaz.*, ii. 35; also *Woodman and Tidy.*) The recent root is highly irritant, and is said, when bruised and applied to the skin, to be capable of producing vesication. The medicine was well known to the ancients, and has been employed by modern physicians as a hydragogue cathartic in *dropsy*, but is now superseded by jalap. Dose of powdered root, from a scruple to a drachm (1·3–3·9 Gm.).* (See *Tinctura Bryoniæ.*)

BUCHU. U.S. (Br.) Buchu.

(BŪ′ĊHŪ.)

"The leaves of Barosma betulina (Thunberg), Bartling et Wendland, and Barosma crenulata (Linné), Hooker (nat. ord. Rutaceæ)." *U. S.* "The dried leaves of Barosma betulina, Bart. and Wendl." *Br.*

Buchu Folia, *Br.*; **Folia Bucco, Folia Diosmæ, s. Barosmæ; Feuilles de Bucco (Booko, Buchu)**, *Fr.*; **Buckublätter, Buccoblätter**, *G.*

The leaves of the official and other Barosmas (so named from *βαρύς*, heavy, and *ὀσμή*, odor), and of some *Agathosmas*, are collected by the Hottentots, who value them on account of their odor, and, under the name of *bookoo* or *buchu*, rub them, in the state of powder, upon their greasy bodies.

Gen. Ch. Calyx five-cleft or five-parted. Disk lining the bottom of the calyx, generally with a short scarcely prominent rim. *Petals* five, with short claws. *Filaments* ten; the five opposite the petals sterile, petaloid; the other five longer, subulate. *Style* as long as the petals. *Stigma* minute, five-lobed. *Fruit* composed of five cocci, covered with granular dots at the back. These plants are small shrubs, with opposite leaves and peduncled flowers. *Lindley.*

The official species are all erect, slender shrubs with opposite leaves, dotted with conspicuous pellucid oil glands, smooth, angular, purplish branches, often of a purplish color, white flowers, and a fruit of five erect carpels. They are chiefly distinguished by their leaves.

Barosma crenata. Lindley, *Flor. Med.* p. 213.—*Diosma crenata.* De Cand. *Prodrom.* i. 714.—*Barosma crenulata.* Hooker. *B. & T.* 46. The leaves are opposite, ovate or obovate, acute, serrated and glandular at the edge, coriaceous, and full of small pellucid dots on the under surface. The flowers are white or of a reddish tint, and stand solitarily at the end of short, lateral leafy shoots.†

B. serratifolia. Willd. *Sp. Plant.* p. 257; Lind. *Flor. Med.* p. 213; *B. & T.* 47. The leaves are linear lanceolate, equally narrowed towards either end, three-nerved, with a truncate apex, which is always furnished with an oil-cell, and a sharply serrulate margin. Their length is from an inch to an inch and a half; their width one-fifth of an inch.

B. betulina. Bartling. The leaves of this species are cuneate-obovate, apex recurved, with their margin sharply denticulate by spreading teeth. They are from one-half to three-quarters of an inch long, by three-tenths to five-tenths of an inch wide.

Properties. Buchu leaves are officially described as follows. "About 15 Mm. long, roundish-obovate with a rather wedge-shaped base, or varying between oval and obovate, obtuse, crenate or serrate, with a gland at the base of each tooth, dull yellowish-green, thickish, pellucid-punctate; odor and taste strongly aromatic, somewhat mint-like, pungent and bitterish."

* Prof. Petresco asserts that *Bryonia alba* is physiologically different from *Bryonia dioica;* that it contains a glucoside, *brein*, which is a powerful stimulant to the arterioles, rendering the drug a valuable remedy in the treatment of *post-partum hemorrhage* and other *metrorrhagias.*

† C. J. S. Thompson has found that the leaves of *B. serratifolia* yield only 3·45 per cent. of resin and 1 per cent. of volatile oil, whilst those of *B. crenulata* yield 3·75 per cent. of resin and 1·6 per cent. of volatile oil, and those of *B. betulina* give 4·25 per cent. of resin and 1·45 per cent. of volatile oil: so that *B. serratifolia* would seem to be the least active of the official species. (*P. J. Tr.*, xxi. 1890.)

U. S. "The transverse section exhibits an epidermis whose cells contain yellow sphero-crystals; the inner walls of these cells are thick and rich in mucilage. Odor and taste strong and characteristic." *Br.* The leaves of *B. crenata* constitute the *short buchu* or *round buchu*, whilst those of *B. serratifolia* are the *long buchu* of commerce. The leaves of *B. crenulata* are at present comparatively infrequent in commerce, the parcels usually consisting of those of one of the other species almost unmixed. The species can be recognized by the characters already given The leaves of the *Empleurum serrulatum* sometimes occur mixed with buchu leaves, occasionally constituting the bulk of the parcel. They are to be distinguished by their acrid taste and peculiar odor and by being longer and narrower than any buchu leaf, with a sharp-pointed apex, parallel sides, and coarse denticulation. Further, according to Holmes, when the leaf of a Barosma is held up to the light the lateral veins appear straighter, longer, and more strongly developed than in the leaves of the Empleurum.*

Flückiger obtained from *B. betulina* 1·56 per cent. of volatile oil, which had the odor of peppermint rather than of buchu, and deviated the plane of polarization considerably to the left. On exposure to cold it furnished a camphor, which, after re-solution in alcohol, crystallized in needle-shaped forms. After repeated purification in this manner, the crystals of *Barosma camphor*, or *diosphenol*, have a peppermint odor; they fuse at 85° C. and begin to sublime at 110° C. After fusion they again solidify only at 50° C. Submitted to elementary analysis, the crystals yielded 74·08 per cent. of carbon and from 9 to 10 per cent. of hydrogen. Barosma camphor is abundantly soluble in carbon disulphide. The crude oil from which the camphor had been separated had a boiling point of about 200° C., quickly rising to 210° C. or even higher. The oil which distilled between these temperatures, rectified over sodium, gave approximately the formula $C_{10}H_{18}O$. (*Pharmacographia*, 2d ed., p. 109.) Prof. Spica examined *B. crenata* and found the volatile oil to differ from that obtained by Prof. Flückiger from *B. betulina;* the stearopten was similar to diosphenol, but upon analysis gave the figures $C_{19}H_{16}O_2$, and hence is regarded by Prof. Spica as an oxycamphor. The elæopten was a greenish-yellow oil, having a pleasant odor and a pungent, peppermint-like taste; by fractioning, it was separated into a portion isomeric with borneol, resembling thymol in smell and taste, and having the composition $C_8H_{12}O$, to which the name of *dioscamphor* was given. A substance extracted by alcohol from the residue after the removal of the oil Prof. Spica named *diosmin.* (*P. J. Tr.*, 1885, p. 106.) The results of Spica were confirmed by Shimoyama (*Amer. Journ. Phar.*, 1888, p. 624), who made several simple derivatives of diosphenol, and then prepared from it, by prolonged digestion with alcoholic potash, *diolic acid*, $C_{10}H_{18}O_3 + H_2O$, forming white crystalline needles, melting at 96°–97° C., and a compound to which he gives the name *diolalcohol.* Wayne's experiments (*A. J. P.*, 1876, p. 19) appear to indicate that the oil also contains a substance capable of being converted into salicylic acid. Prof. J. M. Maisch believes that buchu leaves do not contain salicylic acid, although the stearopten of the oil gives a blackish color with ferric chloride. (*A. J. P.*, July, 1881.) The yield of ash varies, according to the researches of H. W. Jones (*P. J. Tr.*, ix. 673), from 4·69 to 4·40 in *B. betulina*, 4·32 to 5·39 in *B. crenulata*, 5·03 to 5.22 in *B. serratifolia;* the ash itself was remarkable as containing a great deal of manganese. The short-leaved buchu was found by Mr. P. W. Bedford to yield an average of 1·21 per cent. of volatile oil; while the long-leaved, though more highly valued in the market, gave only 0·66 per cent., showing its great inferiority in strength. (*Proc. A. P. A.*, 1863, p. 211.)

Medical Properties. The Hottentots have long used buchu in a variety of diseases. From these rude practitioners the remedy was borrowed by the resident English and Dutch physicians, by whose recommendation it was employed in Europe, and has come into general use. Its activity depends upon the volatile oil, which is eliminated by the kidneys. Under its action there is no marked increase in the amount of the urine, hence the remedy is of no value in *dropsies;* but the oil affects very decidedly the mucous membrane of the genito-urinary tract. The remedy is very useful in *diseases of the urinary organs*, such as *gravel*, *chronic catarrh of the bladder*, *morbid irritation of the bladder and urethra*, *diseases of the prostate*, and *retention or incontinence of urine* from a loss of tone in the parts concerned in its evacuation. It should be given when the inflammation is not severe, but not when it is in that condition of chronicity requiring oil of turpentine, tincture of cantharides, or other more stimulant diuretics. The best preparation is the fluid extract; dose, a fluidrachm (3·7 C.c.) three or four times a day.

* John C. Umney (*P. J. Tr.*, March, 1895) finds that these leaves contain 0·64 per cent. of a peculiar volatile oil. There is no reason to believe that they possess the therapeutical properties of buchu.

BUTYL-CHLORAL HYDRAS. Br. Butyl-Chloral Hydrate.

$C_4H_5Cl_3O, H_2O$. (BŪ'TĬL-KLŌ'RAL HĪ'DRĂS.)

"Butyl-Chloral Hydrate, or trichlorbutylidene glycol, $CH_3.CHCl.CCl_2.CH(OH)_2$, is a crystalline hydrate obtained by the addition of water to the liquid butyl-chloral produced by the action of chlorine gas on aldehyde." *Br.*

Hydrous Butyl Chloral; Croton Chloral Hydrate, wrongly so called, *Br.;* Chloral butylicum; Butyl chloralhydrate; Hydrate de chloral butylique, *Fr.;* Butylchloralhydrat, *G.*

This substance was discovered by Krämer and Pinner, of Berlin, during an examination of the accumulated by-products of the chloral factory of Schering. It was named croton-chloral hydrate because it was believed to bear a relationship to crotonic acid, the peculiar acid of croton oil; this was subsequently disproved by Pinner, who showed that it belonged to the butyl series. (*Ber. d. Chem. Ges.*, vii. 1321, 1561.) It is made by passing dry chlorine through aldehyde cooled to —10° C. (14° F.), in an apparatus similar to that used in making chloral. Fractional distillation is resorted to, and the product boiling between 163° C. (325·4° F.) and 165° C. (329° F.) is reserved; this is butyl-chloral, a colorless oily liquid. The necessary amount of water is added, and butyl-chloral hydrate is obtained.

Properties. Butyl-chloral hydrate occurs in the form of crystalline, micaceous scales of a pungent odor, sparingly soluble in water, freely soluble in alcohol, hot water, and glycerin, but insoluble, or nearly so, in chloroform, a property which may be employed to separate it from ordinary chloral hydrate. When treated with caustic alkalies it is converted into formic acid, potassium chloride, and allylene dichloride, $C_3H_4Cl_2$. The British Pharmacopœia describes it as "In pearly white, trimetric laminæ, having a pungent but not acrid odor, and an acrid nauseous taste. It fuses at about 172° F. (77·8° C.) to a transparent liquid, which, in cooling, commences to solidify at about 160° F. (71·1° C.). Soluble in about 50 parts of *water*, and in its own weight of *glycerin* or of *alcohol* (90 per cent.); it slowly dissolves in 20 parts of *chloroform*. The aqueous solution is neutral or but slightly acid to *litmus*. It does not yield chloroform when heated with *solution of potassium hydroxide* or with *milk of lime* (absence of chloral hydrate."

Medical Properties and Uses. Butyl-chloral was proposed by Liebreich, in 1870, as a remedy for the treatment of *trigeminal neuralgia*. He states that a drachm (3·88 Gm.) of it causes deep sleep, accompanied by anæsthesia of the head, with complete loss of irritability of the eyeball and of the trigeminal nerve, the circulation being kept up with great tenacity, and death, if the dose have been large enough, resulting from the arrest of respiration. These statements of Liebreich were contradicted by the research of J. von Mering and of H. W. Schmidt, who found that no anæsthesia was produced unless sufficient doses were given to cause complete narcosis, and that the general course of the symptoms caused by the croton-chloral was exactly parallel to that of those produced by the chloral hydrate. Nevertheless a number of observers have used croton-chloral with asserted good results in the treatment of *tic-douloureux*. The relief obtained is, unfortunately, only temporary and palliative. The drug has been commonly administered in doses of from 5 to 20 grains (0·324 to 1·29 Gm.) in syrup. The safer plan is to give 5 grains (0·324 Gm.) every half-hour until 30 grains (1·94 Gm.) have been taken or relief afforded. The original formula of Liebreich was—Butyl Chloral 5 to 10 parts; Glycerin 20 parts; Distilled Water 130 parts. Dose, half a fluidounce, followed in five minutes by a second dose, ten minutes later by a third dose, unless relief is afforded. It is not sure that such medication would be safe. Dose of British Pharmacopœia, from five to twenty grains (0·324 to 1·3 Gm.). For experiments in making dispensing solutions of butyl-chloral, see *Proc. A. P. A.*, 1894, 578.

CAFFEINA. U. S., Br. Caffeine. [Theine.]

$C_8H_{10}N_4O_2.H_2O$; 211·68. (KĂF-FĒ-Ī'NĄ.) $C_8H_{10}N_4O_2.H_2O$; 212.

"A feebly basic, proximate principle, obtained from the dried leaves of Thea sinensis, Linné (nat. ord. Ternstrœmiaceæ), or from the dried seeds of Coffea arabica, Linné (nat. ord. Rubiaceæ), and found also in other plants."* *U. S.*. "An alkaloid, $C_8H_{10}N_4O_2,H_2O$, usually

* The United States Pharmacopœia allows caffeine to be prepared from either one of the ordinary commercial sources, but because tea-leaves contain a much larger percentage of the alkaloid than does the coffee berry, and are frequently thrown into commerce in a damaged condition, unfit for use as a beverage, commercial caffeine is almost always prepared from them. If the assertion of Dr. Thomas J. Mays, that theine, though chemically identical with caffeine, is physiologically different, be confirmed, it will become necessary to recognize theine as an official alkaloid, and direct that caffeine be prepared from coffee. The argument that tea and coffee differ in their gross effects on the human body, and that therefore the alkaloids cannot be identical, has no force, because coffee contains an active empyreumatic oil, developed during the process of roasting. How far the conclusions arrived at by Dr. Mays

obtained from the dried leaves of Camellia Thea, Link, or the dried seeds of Coffea arabica, Linn. Crystallized from aqueous solution, it contains one molecule of water." *Br.*

Caffeia, Theina, Guaranina.

Caffeine (*Caffeia*) was first discovered by Runge, and afterwards by Pelletier and Caventou and Robiquet. Strecker first proved it to be methyl-theobromine by making it from theobromine synthetically.* (*Ann. Chem. Pharm.*, 118, 170.) It may be obtained in the following manner. Exhaust bruised coffee by two successive portions of boiling water, unite the infusions, add lead acetate in order to precipitate various principles accompanying the caffeine, filter, decompose the excess of lead acetate in the filtered liquor by hydrogen sulphide, concentrate by evaporation, and neutralize with ammonia. The caffeine is deposited in crystals upon cooling, and may be purified by redissolving in water, treating with animal charcoal, and evaporating. H. Leuchsenring obtains caffeine by availing himself of its property of subliming unchanged by heat. He precipitates a concentrated decoction of coffee by a weak solution of lead acetate, filters, evaporates to dryness, mixes the residue with sand, and sublimes as in Mohr's process for procuring benzoic acid. (*A. J. P.*, xxxii. 25.) Still another method, proposed by Vogel, is to treat coffee, ground to powder, with benzin, which dissolves the caffeine, and an oily substance, to separate the benzin by distillation, to treat the residue with boiling water, which dissolves the caffeine, and deposits it in a crystalline form, after filtration and concentration. (*Journ. de Pharm.*, 3e sér., xxxv. 436.) Paul and Cownley's process for estimating the caffeine in coffee is to mix finely powdered coffee with moist lime, and exhaust with alcohol by hot repercolation. The alcohol is evaporated off, and the residue mixed with water and a few drops of diluted sulphuric acid; the mixture is filtered, and the filtrate and washings, when cool, treated with chloroform to wash out the alkaloid; the chloroformic solution is evaporated in a tared capsule, and the residue weighed as caffeine. (*P. J. Tr.*, 1887, p. 565. For another method, by E. D. Smith, see *Pharm. Era*, 1887, 17; see also *A. J. P.*, 1892, 468, and 1893, 338; *Journ. de Pharm. et de Chim.*, 1893, 545; *Apoth. Zeit.*, 1893, 132; *Chem. and Drug.*, 1893, 210; *Pharm. Era*, 1897, 391.)

Caffeine is prepared on a considerable scale from damaged tea. The tea is exhausted with boiling water, the decoction boiled with litharge or lead acetate, and the filtered solution evaporated until the alkaloid crystallizes out on cooling. The product can be purified by resublimation or by crystallization from hot water. (Allen, *Commerc. Org. Anal.*, 2d ed., vol. iii., part ii., 474.)

Properties. Caffeine is a feeble base, capable of forming definite compounds with mineral acids but not with organic acids; the latter, however, increase its solubility in water and other liquids. (See *Caffeina Citrata.*) Caffeine is in "fleecy masses of long, flexible, white crystals, possessing a silky lustre, without odor, having a bitter taste, and permanent in the air. Soluble, at 15° C. (59° F.), in 80 parts of water, 33 parts of alcohol, 555 parts of ether, or 7 parts of chloroform. Also soluble in about 2 parts of boiling water, and very soluble in boiling alcohol. When heated to 100° C. (212° F.), Caffeine loses its water of crystallization, and at 229° C. (444·2° F.) it melts, forming a colorless liquid. When ignited, Caffeine is completely volatilized without charring or leaving a residue. Caffeine is neutral to litmus paper. On dissolving a small quantity of Caffeine in concentrated sulphuric acid, and adding a minute fragment of potassium dichromate to the liquid, the latter will acquire a yellowish-green color, which gradually becomes green. If a small quantity of Caffeine be dissolved in about 1 C.c. of hydrochloric acid, a little potassium chlorate added, the whole evaporated to dryness on a water-bath, and the capsule then inverted over a vessel containing a few drops of ammonia water, the residue

by experiments upon frogs must be accepted still remains a matter of opinion. We think, however, that further physiological studies of the three alkaloids theine, caffeine, and guaranine are necessary before their physiological diversity can be considered established. Dunston and Shepheard (*Journ. Chem. Soc.*, 1893, 195) reviewed the question of the identity of caffeine and theine with great care, and established the complete chemical identity of the two by a study of a number of derivatives. The clinical results obtained by Dr. Mays (*Med. News*, vol. xlviii.) are sufficient to warrant the trial of theine as a local anæsthetic injected in a dose of a third of a grain over painful nerves.

* In an examination of 25 varieties of coffee, Prof. Dragendorff found a variation in the amount of caffeine of from 0·6 to 2·2 per cent. The most important varieties were as follows:

Brown Preang	0·71 per cent.	First native Ceylon	0·87 per cent.
Finest Mocha	0·64 "	Second " "	1·54 "
Yellow Menado	1·22 "	Third " "	1·59 "
Finest plantation Jamaica	1·43 "	Costa Rica	1·18 "
First Surinam	1·78 "	West Indian	1·22 "
Pearl plantation Ceylon	0·78 "	Rio	1·14 "
Yellow Java	0·88 "	Jamaica	0·67 "
Gray Java	2·21 "	Santos	1·46 "

will acquire a rich purple color, which is destroyed by alkalies. Caffeine should dissolve in strong sulphuric or nitric acid without producing a color (absence of *organic impurities*). Its aqueous solution should not be precipitated by mercuric potassium iodide test-solution (absence of *other alkaloids*)." *U. S.* The British Pharmacopœia describes it as "Soluble in 80 parts of cold *water*, the solution having a faintly bitter taste and being neutral to *litmus*. Easily soluble in boiling *water*, *alcohol* (90 per cent.), or *chloroform;* sparingly soluble in *ether*. It dissolves without color in *sulphuric* and *nitric acids*. At 212° F. (100° C.) the crystals lose 8·49 per cent. of their weight, and at a higher temperature melt and volatilize without decomposition. Treated with a crystal of *potassium chlorate* and a few drops of *hydrochloric acid*, and the mixture evaporated to dryness in a porcelain dish, a reddish residue results, which becomes purple when moistened with *solution of ammonia*. In an aqueous solution of the alkaloid, *tannic acid* gives a white precipitate soluble in excess of the reagent, but no precipitate is caused by *solution of potassium iodide* containing mercuric iodide (distinction from other official alkaloids)." It is precipitated from its aqueous solution by no reagent except tannic acid and solution of potassio-mercuric iodide. When this solution, made by saturating potassium iodide with mercuric oxide, is added to a solution of caffeine, a precipitate is produced, which soon takes the form of white, shining, acicular crystals. This reaction is proposed as a test of caffeine by Prof. Dellfs; for though the same solution will precipitate the other alkaloids, the product is always amorphous. (*Chem Gaz.*, Feb. 15, 1855.) Tanret proposes to increase the solubility of caffeine by adding definite proportions of sodium benzoate, cinnamate, or salicylate, which form with it double salts rich in alkaloid (45·8, 58·9, and 61 per cent. respectively). These are well adapted for hypodermic administration, as they are all freely soluble in water. The proportions recommended are as follows: *caffeine-sodium benzoate* (caffeine, 244, sodium benzoate, 288); *caffeine-sodium cinnamate* (caffeine, 244, sodium cinnamate, 170); *caffeine-sodium salicylate* (caffeine, 244, sodium salicylate, 160). (*L'Union Pharm.*, xxxvii. 394.) Caffeine is remarkable for containing a larger proportion of nitrogen than does almost any other proximate vegetable principle, in this respect equalling some of the highly animalized products.

Medical Properties and Uses. There have been a few cases of poisoning by caffeine; a drachm of citrated caffeine swallowed by an adult was followed by burning at the throat, giddiness, faintness, nausea, tremor of the extremities, abdominal pain, mental distress, great cardiac oppression, and finally collapse. Consciousness was not impaired, and there was no headache until the patient began to recover. A decoction of 8 ounces of freshly roasted coffee, taken for the purpose of producing abortion, caused pronounced choreic tremors, great restlessness, quickened respiration, and rapid pulse, with very strong, even violent, heart-beats. In doses of 3 to 5 grains caffeine produces in the healthy individual a peculiar wakefulness, with stimulation of the cerebrum, and some increase of the urinary secretion and force of the pulse. There is usually marked increase of the mental activity and of the capability for sustaining mental work. Abont two hours after the ingestion of 12 grains by Dr. Pratt, there were intense physical restlessness and mental anxiety, with obstinate sleeplessness, active and persistent thinking, general muscular tremulousness, and frequent urination.

Given in large dose to the lower animals, caffeine* produces hurried respiration, restlessness, slightly lowered followed by markedly elevated temperature, tetanic and clonic convulsions, progressive paralysis, and finally death from paralytic arrest of respiration. The cause of the convulsions in mammals is not determined, but in the frog they are of spinal origin, for both Pratt and Le Blond have found that section of the cord does not arrest them below the point of section, whilst destruction of the cord (Pratt and Leven) prevents their development. It would appear, therefore, that caffeine acts upon the frog as a stimulant to the motor side of the spinal cord, and it is probable that the physical restlessness and tremulousness produced in man are largely of spinal origin. Upon the motor nerves caffeine has no effect, but there is some reason for suspecting that it exerts a very feeble influence upon the sensory nerves. Upon the muscles caffeine acts as a powerful poison; when an isolated piece of the gastrocnemius of the frog is thrown into a one-per-cent., or even weaker, solution of the citrate of caffeine, it becomes contracted and stiff, and unable to respond to the galvanic current in from two to

* *Caffeine Derivatives.* Professor W. Filehne (*Archiv f. Anat. und Physiol.* (*Physiolog. Abtheil.*), 1886, abstract *Therap. Gaz.*, 1886) has made an investigation of the physiological action of certain derivatives and decomposition products of caffeine,—namely, hydroxy-caffeine, diethoxy-hydroxy-caffeine, ethoxy-caffeine, caffeidine, caffuric acid, hypo-caffeine, caffoline, guarineine, uric acid. Believing that the introduction into the caffeine molecule of an atom which is depressing to the heart would modify physiologically the action of the molecule, J. W. Pickering has made studies with *chloro-caffeine* (chlorotrimethylxanthine), and finds that, whilst it is a powerful diuretic and a cerebral stimulant, it has very little influence upon the heart itself. (*Journ. f. Physiol.*, 1895; *Journ. Chem. Soc.*, 1895.)

three minutes. It has been abundantly proved that it is the muscle-fibre which is affected, and it seems to be established that the paralysis is preceded by a period of excitement, during which the contractility of the muscle is increased both in its sensitiveness to stimuli and in its power. The action of caffeine upon the circulation is distinct, as has been shown by Leven, Binz, and other observers. The alkaloid produces in the mammal elevation of the arterial pressure, which is at least in part due to a direct action upon the heart; caffeine in small dose reinforcing the isolated frog's heart, and giving to its contractions more amplitude and more energy. Prof. Reichert found that even after destruction of the vaso-motor centres in the medulla oblongata, caffeine still elevates the arterial pressure. He believes that this rise of the arterial pressure, which must be independent of the vaso-motor centres, is due to a direct action of the caffeine upon the muscle-fibres in the vessel-walls. Direct proof of this, however, seems to be wanting, and it remains uncertain whether the rise of pressure is due entirely or only in part to the cardiac stimulation. In advanced stages of caffeine poisoning the arterial pressure falls, both the heart and the vaso-motor system being depressed or paralyzed. The pulse-rate is usually but not always increased by caffeine; sometimes it is distinctly slowed; these results are probably due to some influence exerted upon the pneumogastric system.

One of the most constant symptoms produced in man by overdoses of caffeine is excessive diuresis, and experiments made upon the lower animals show that caffeine acts as a diuretic not only by influencing the circulation, but also by directly affecting the secreting cells of the kidney or the nerves which dominate those cells, the probabilities being in favor of the first of these theories of action. According to Prof. Schroeder, not only the water but also the solids of the urine are increased.

The question whether caffeine has an influence upon tissue-changes and the consequent nitrogenous elimination cannot be considered as distinctly answered, though the most probable conclusion is that the action of caffeine upon urea elimination and upon general nutrition is not direct or pronounced. Whilst the therapeutic dose of caffeine is broken up in the body with the formation of methylxanthine, which escapes with the urine, the toxic dose is at least in part eliminated by the kidney unchanged.

Caffeine is a valuable remedy in practical medicine as a cerebral and cardiac stimulant and as a diuretic. In undue *somnolence*, in *nervous headache*, in *narcotism*, also, at times, when the exigencies of life require excessively prolonged wakefulness, caffeine may be used as the most powerful agent known for producing wakefulness. In a series of experiments, Dr. J. Hughes Bennett found that within narrow limits there is a direct physical antagonism between caffeine and morphine. Coffee and caffeine in narcotic poisoning are of value as a means of keeping the patient awake, and of stimulating the respiratory centres.

As a cardiac stimulant, caffeine may be used in any form of *heart-failure;* the indications for its use are those which call for the employment of digitalis. It is superior to digitalis in never disagreeing with the stomach, in having no distinctive cumulative tendency, and in the promptness of its action. It is pronouncedly inferior to digitalis in the power and certainty of its action, and in the permanence of its influence once asserted. As a diuretic it is superior; it is very valuable in the treatment of *cardiac dropsies*, and is often useful in *chronic Bright's disease* when there is no irritation of the kidneys.

On account of its tendency to produce wakefulness, it is usually better to mass the doses early in the day, at least six hours being left between the last dose and the ordinary time for sleep. From eight to fifteen grains may be given in the course of a day in severe cases. If tried, it would probably prove a useful drug in cases of *sudden collapse* from various causes. The ordinary salts of it are, however, not available for hypodermic use, because they are decomposed in the presence of water. The double benzoate of sodium and caffeine has been proposed as moderately stable and free from irritant properties: the following formula has also been commended by M. Tanret for hypodermic use: Sodii salicyl., 31 gr.; Caffeinæ, 40 gr.; Aquæ destillatæ, 60 gr. For internal administration the soluble preparation known as citrated caffeine is usually preferred. Dose, from 3 to 8 grains (0·194 to 0·51 Gm.).

CAFFEINA CITRATA. U. S. (Br.) Citrated Caffeine.

(CĂF-FE-Ī'NĄ CĪ-TRĀ'TĄ.)

"An unstable compound, $C_8H_{10}N_4O_2,C_6H_8O_7$, prepared from Caffeine and Citric Acid." *Br.*

Caffeinæ Citras, *Br.*, Caffeine Citrate.

"Caffeine, *fifty grammes* [or 1 ounce av., 334 grains]; Citric Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, hot, *one hundred cubic centimeters* [or 3 fluidounces, 183

minims]. Dissolve the Citric Acid in the hot Distilled Water, add the Caffeine, and evaporate the resulting solution, on a water-bath, to dryness, constantly stirring towards the end of the operation. Reduce the product to a fine powder, and transfer it to well-closed bottles." *U. S.*

"Caffeine, 1 *ounce* (Imperial) or 20 grammes; Citric Acid, 1 *ounce* (Imp.) or 20 grammes; Distilled Water, 2 *fl. ounces* (Imp. meas.) or 40 cubic centimetres. Dissolve the Citric Acid in the Distilled Water; stir the Caffeine into the heated solution; evaporate to dryness on a water-bath, constantly stirring towards the end of the operation; reduce to a fine powder." *Br.*

This is a new preparation of the U. S. Pharmacopœia; although defined as a weak compound of caffeine and citric acid, it is not regarded by chemists as a chemical salt, but as a mechanical mixture of the two substances composing it. The British Pharmacopœia gives the following as its chemical formula: $C_8H_{10}N_4O_2,H_3C_6H_5O_7$. It is officially described as "a white powder, odorless, having a purely acid taste and an acid reaction. One part of Citrated Caffeine forms a clear, syrupy solution with about 3 parts of water.* Upon dilution with water, this yields a white precipitate (caffeine), which redissolves when about 25 parts of water have been added. It is also soluble in a mixture of 2 volumes of chloroform and 1 volume of alcohol." *U. S.* The Br. Pharm. describes it as "A white inodorous powder with an acid and faintly bitter taste and an acid reaction on *litmus*. It is soluble in 32 parts of *water*, and also in a mixture of 2 parts of *chloroform* with one part of *alcohol* (90 per cent.). With 3 parts of *water* it forms a clear syrupy solution, but more *water* dissociates the salt and affords a white precipitate of caffeine which redissolves when excess of *water* is added. Heated in the air, the salt is charred and then burnt, leaving a mere trace of ash. It affords the reactions mentioned under 'Caffeina,' and also those characteristic of citrates."

Medical Properties and Uses. Citrated caffeine is possessed of the physiological and therapeutical properties of caffeine. The dose is from three to eight grains (0·194 to 0·51 Gm.).

CAFFEINA CITRATA EFFERVESCENS. U. S. (Br.) Effervescent Citrated Caffeine.

(KĂF-FĒ-Ī'NĄ CĪ-TRĀ'TĄ ĔF-FĔR-VĔS'CĔNS.)

Caffeinæ Citras Effervescens, *Br,* Effervescent Caffeine Citrate.

"Caffeine, *ten grammes* [or 154 grains]; Citric Acid, *ten grammes* [or 154 grains]; Sodium Bicarbonate, *three hundred and thirty grammes* [or 11 ounces av., 279 grains]; Tartaric Acid, *three hundred grammes* [or 10 ounces av., 254·7 grains]; Sugar, in very fine powder, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Alcohol, *a sufficient quantity*. To make *one thousand grammes* [or about 35 ounces av.]. Triturate the solid ingredients, separately well dried, to a fine, uniform powder. Mix this with Alcohol to a soft paste and rub it through a No. 6 tinned-iron sieve or enamelled colander. Then dry it, and reduce it to a coarse, granular powder. Keep the product in well-stoppered bottles." *U. S.*

"Sodium Bicarbonate, in powder, 51 *ounces* (Imperial) or 510 grammes; Tartaric Acid, in powder, 27 *ounces* (Imp.) or 270 grammes; Citric Acid, in powder, 18 *ounces* (Imp.) or 180 grammes; Refined Sugar, in powder, 14 *ounces* (Imp.) or 140 grammes; Caffeine Citrate, 4 *ounces* (Imp.) or 40 grammes. Mix the Caffeine Citrate, Tartaric Acid, and Citric Acid; with this product thoroughly incorporate the mixed Sodium Bicarbonate and Refined Sugar; place in a dish or pan of suitable form heated to between 200° and 220° F. (93·3° and 104·4° C.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54·4° C.). The product should weigh about 100 *ounces* (or 1000 grammes)." *Br.*

This effervescent granulated salt contains 1 per cent. of caffeine. The methods of granulation are not identical in the above processes; alcohol is used in the U. S. P. to give a pasty consistence to the ingredients before granulating. In the British process no alcohol is used; this effects a saving in the expense of manufacturing, while the use of heat with skilful manipulation has been found to produce equally good results. Samples of effervescent citrated caffeine have been found in the market very deficient in caffeine; the sweetening is sometimes effected by the use of saccharin instead of sugar. The powder affords an agreeable method of administering citrated caffeine. The dose is a teaspoonful in water, to be taken during effervescence.

* M. A. Harper examined a number of commercial samples of citrated caffeine, and found them all fairly to represent the official preparation. He reports, however, that the official test for solubility in water should be altered slightly, and the words "when gently warmed" be inserted, because a sample made strictly according to the U. S. P. would not conform to the test without warming. (*West. Drug.*, 1897, 253.)

CALAMUS. U.S. Calamus. [Sweet Flag.]

(CĂL'Ą-MŬS.)

"The rhizome of Acorus Calamus, Linné (nat. ord. Aroideæ)." *U. S.*

Rhizoma Calami, *P.G.;* Radix Calami Aromatici, Radix Acori; Acore vrai, Acore odorant, *Fr.;* Kalmuswurzel, *G.;* Calamo aromatico, *It., Sp.*

Gen. Ch. Spadix cylindrical, covered with florets. *Corolla* six-petalled, naked. *Style* none. *Capsule* three-celled. *Willd.*

Acorus Calamus. Willd. *Sp. Plant.* ii. 199; Barton, *Med. Bot.* ii. 63; *B. & T.* 279. The sweet flag, or calamus, has a perennial, horizontal, jointed, somewhat compressed root (rhizome), from half an inch to an inch thick, sometimes several feet in length, sending off numerous round and yellowish or whitish radicles from its base, and bunches of brown fibres resembling coarse hair from its joints, internally white and spongy, externally whitish with a tinge of green, variegated with triangular stains of light brown and rose color. The leaves are all radical, sheathing at the base, long, sword-shaped, smooth, green above, but, near their origin from the root, of a red color, variegated with green and white. The scape or flower-stem resembles the leaves, but is longer, and from one side, near the middle of its length, sends out a cylindrical spadix, tapering at each end, about two inches in length, and crowded with greenish-yellow flowers. These are without calyx, and have six small, concave, membranous, truncated petals. The fruit is an oblong capsule, divided into three cells, and containing numerous oval seeds.*

This is an indigenous plant, growing throughout the United States, in low, wet, swampy places, and along the sides of ditches and streams, and flowering in May and June. It is also a native of Europe and Western Asia; and a variety is found in India. The European plant differs slightly from the American. The leaves as well as the root have an aromatic odor; but the latter only is employed. It should be collected late in the autumn, or in the spring. After removal from the ground, the rhizomes are washed, freed from their fibres, and dried with a moderate heat. By drying they lose nearly one-half their diameter, but are improved in odor and taste.

Properties. The roots, as found in commerce, are "in sections of various lengths, unpeeled, about 2 Cm. broad, subcylindrical, longitudinally wrinkled; on the upper surface marked with leaf-scars forming triangles, and on the lower surface with the circular scars of the rootlets in wavy lines; externally reddish-brown, somewhat annulate from remnants of leaf-sheaths; internally whitish, of a spongy texture, breaking with a short, corky fracture, showing numerous oil-cells and scattered wood-bundles, the latter crowded within the subcircular endoderm. It has an aromatic odor, and a strongly bitter taste." *U. S.* Their texture is light and spongy, their color internally whitish or yellowish white, and their fracture short and rough. A variety imported from Germany consists exclusively of the interior portion of the root. The pieces are usually long, slender, irregularly quadrangular, and of a grayish-white color.

The odor of calamus is strong and fragrant; its taste warm, bitterish, pungent, and aromatic. Its active principles are taken up by boiling water. From 100 parts of the fresh root of the European plant, Trommsdorff obtained 0·1 of volatile oil, 2·3 of soft resin, 3·3 of extractive with a little potassium chloride, 5·5 of gum with some potassium phosphate, 1·6 of starch analogous to inulin, 21·5 of lignin, and 65·7 of water. Sixteen ounces of the dried root afforded to Neumann about two scruples of volatile oil. The oil is at first yellow, but ultimately becomes red, and has the smell and taste of calamus. Kurbatow (*Annal. d. Chemie*, vol. 173, p. 4) examined oil of calamus, and found that the portion boiling below 170° C. (338° F.) yielded after treatment with sodium a terpene, $C_{10}H_{16}$, having sp. gr. ·8793 at 0° C. (32° F.), and having a boiling point of 158° C. (316·4° F.). According to Schimmel's Report (April, 1895), all oils of calamus having a lower rotary power than + 10° and those which do not yield clear solutions with any proportion of 90 per cent. alcohol should be rejected. The extractive matter has an acrid and sweetish taste. H. Thomas obtained from calamus rhizomes a bitter principle, which he named *acorin*, in the form of a clear, thick, yellow liquid, having a neutral reaction, aromatic odor, and bitter, aromatic taste. It is a glucoside, having the formula $C_{36}H_{60}O_6$, splitting into oil of calamus and sugar; insoluble in water, but readily soluble in absolute alcohol, methylic alcohol, and chloroform. By oxidation *acoretin*, a neutral resin, is

* *Japanese Calamus.* A root not to be distinguished from European calamus root has entered commerce from Japan. It yields five per cent. of a highly aromatic essential oil, having a specific gravity of 0·991 at 16° C.; one part dissolving in 500 parts of fifty per cent. spirit. It boils at 210° to 290° C., yielding at the lower temperature an oil with a characteristic calamus odor, and at the higher temperature one with a peculiar sesquiterpene odor.

formed, and from the extract remaining after the acorin is removed Thomas obtained an alkaloid which he named *calamine;* this is crystalline, insoluble in water and ether, but soluble in alcohol, chloroform, and acetone. (*Archiv d. Pharm.*, 1886, 465; *P. J. Tr.*, 1886, 1085.) Calamus is sometimes attacked by worms, and deteriorates by keeping. The India variety is more slender than the European, and has a stronger and more pleasant flavor.

Medical Properties and Uses. Calamus is a feeble aromatic, which may be used with advantage in pain or uneasiness of the stomach or bowels arising from *flatulence*, and as an adjuvant to tonic or purgative medicines. It was probably known to the ancients, and is supposed to have been the ἄκορον of the Greeks; but the *calamus aromaticus* of Dioscorides was a different product, having been derived, according to Dr. Royle, from a species of *Andropogon*. The medicine is at present not much used. The dose in substance is from a scruple to a drachm (1·3–3·9 Gm.). An infusion, made in the proportion of an ounce of the root to a pint of boiling water, is sometimes given in the dose of a wineglassful (60 C.c.) or more. (See *Extractum Calami Fluidum.*)

CALCIUM. Calcium.

Ca; 39.91. (CĂL'CI-ŭM.) Ca; 40.

This is the metal characteristic of lime, and, consequently, of all calcareous substances. It was obtained by Dr. Matthiessen, in 1855, in masses of the size of a pea, by the electrolysis of calcium chloride with a Bunsen battery. It is a pale yellow metal, remarkably glittering when freshly filed. Its fracture is jagged, becoming granular. It is malleable and very ductile. In a dry air it remains unaltered, but it soon tarnishes in a moist one. It melts at a red heat, and afterwards burns with splendor, forming lime, or calcium oxide. (*Chem. Gaz.*, June 15, 1855.)

Calcium is a very abundant element in nature, existing in the mineral kingdom chiefly as a carbonate, in the form of limestone, marble, chalk, and calcareous spar; and as a phosphate and carbonate in the bones and shells of animals.

CALCII BROMIDUM. U. S. Calcium Bromide.

$CaBr_2$; 199·43. (CĂL'CI-Ī BRŌ'MI-DŭM.) $CaBr_2$; 199·6.

Calcium Bromatum, Bromure de Calcium, Bromure de Chaux, *Fr.;* Brom Calcium, *G.*

"Calcium Bromide should be preserved in well-stoppered bottles." *U. S.* It is prepared by M. Boedecker by first forming a sulphur bromide, by the addition of 20 parts of the flowers of sulphur to 240 parts of bromine; this is added to a milk of lime containing 140 parts of fresh lime. Calcium bromide and sulphate are formed and are readily separated. (*Journ. de Pharm.*, 4e sér., viii. 463.) Mr. Jas. R. Mercein puts five ounces of bromine and two and a half pints of water in a half-gallon specie jar, passes a stream of hydrogen sulphide through the bromine until it is all taken up, filters, drives off excess of hydrogen sulphide by heat, distils the solution of hydrobromic acid thus obtained until four-fifths have passed over, saturates this with excess of precipitated calcium carbonate, filters, and evaporates. (*A. J. P.*, xliv. 100.) Mr. Macdonald (*ibid.*, 1873) employs the following method. Dissolve 4 ounces of ammonium bromide in a pint of water. Put into a flask and bring to the boiling point. Keep boiling, and add milk of lime (made from *pure* calcined lime) in small quantities, until ammoniacal vapors cease to be evolved. The operator can easily tell when this point has been reached, by the sense of smell. Filter the solution, evaporate to a syrupy consistency, remove from the fire, and stir until cold. Tasilly prepares *calcium oxybromide* by adding three parts of calcium oxide in small portions to a solution of one hundred parts of calcium bromide in seventy-five parts of hot water; acicular crystals of calcium oxybromide, $CaBr_2 3CaO, 16H_2O$, are deposited on cooling the filtered solution.

Properties. "A white, granular salt, odorless, of a sharp, saline taste, and very deliquescent. Soluble, at 15° C. (59° F.), in 0·7 part of water, and in 1 part of alcohol; much more soluble at a boiling temperature. At 680° C. (1256° F.) the salt fuses, and at a higher temperature it is partly decomposed, with loss of bromine. The salt is neutral to litmus paper. The aqueous solution (1 in 20) of the salt yields, with ammonium oxalate test-solution, a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If to 5 C.c. of the aqueous solution a few drops of chloroform be added and then 1 C.c. of chlorine water, bromine will be liberated, and, on agitating the mixture, will dissolve in the chloroform with a yellow or brownish-yellow color." *U. S.*

Tests. "If 1 Gm. of the salt be dissolved in 20 C.c. of water, it should form a clear,

colorless solution, leaving no residue (absence of *insoluble impurities*). If to 5 C.c. of this aqueous solution, slightly acidulated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution be added, neither coloration nor turbidity should be perceptible (absence of *arsenic*, *lead*, etc.). The addition of ammonium sulphide test-solution to the aqueous solution should not produce any color or turbidity (absence of *iron*, *aluminum*, etc.). If 5 C.c. of the aqueous solution (1 in 20), slightly acidulated with acetic acid, be completely precipitated with ammonium oxalate test-solution, the filtrate should, on evaporation, leave not more than a trace of fixed residue (limit of *magnesium* and *alkalies*). If diluted sulphuric acid be dropped upon the salt, the latter should not at once assume a yellow color (absence of *bromate*). If to 5 C.c. of the aqueous solution (1 in 20) a few drops of starch test-solution be added, and then chlorine water, drop by drop, no blue color should appear (absence of *iodide*). No turbidity should be produced, if 0·2 C.c. of barium chloride test-solution be added to 5 C.c. of the aqueous solution (absence of *sulphate*). If 1 Gm. of the salt be mixed with 0·5 Gm. of iron filings and 0·5 Gm. of powdered zinc, and heated in a test-tube with 5 C.c. of sodium hydrate test-solution, no ammoniacal vapors should be evolved (absence of *nitrate* or *nitrite*). If 0·25 Gm. of the well-dried salt be dissolved in 10 C.c. of water and 2 drops of potassium chromate test-solution added, it should require 25 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to 99·7 per cent. of the pure salt, a greater amount indicating presence of *chloride*, a smaller amount *other impurities*)." *U. S.*

Medical Properties and Uses. Calcium bromide was proposed by Dr. Hammond, in 1871, as a substitute for the corresponding salt of potash. It has failed to gain much support from the medical profession, but is sometimes employed as an adjuvant in *epilepsy* and *hysteria*. Its action upon the lower animals has been partially investigated by Guttmann (*Phila. Med. Times*, iv. 361), who finds that it is a sedative to the nerve-centres, but lacks the depressant cardiac action of potassium bromide. Dose, from fifteen to thirty grains (0·97–1.95 Gm.).

CALCII CARBONAS PRÆCIPITATUS. U.S., Br. Precipitated Calcium Carbonate. Precipitated Chalk.

$CaCO_3$; 99·76. (CĂL'CI-Ī CĂR'BŌ-NĂS PRÆ-CĬP-I-TĀ'TŬS.) $CaCO_3$; 100.

"The precipitate, $CaCO_3$, obtained by the interaction of calcium chloride and sodium carbonate." *Br.*

Calcaria Carbonica Præcipitata, *P.G.;* Carbonas Calcicus Præcipitatus, Creta Præcipitata; Carbonate de Chaux précipité, Craie précipitée, *Fr.;* Präcipitirter kohlensauer Kalk, *G.*

A formula for this preparation is found in the Pharmacopœia of 1870.*

The processes do not essentially differ. In each a mutual interchange of principles takes place, resulting in the production of sodium chloride which remains in solution, and calcium carbonate which is deposited, $CaCl_2 + Na_2CO_3 = CaCO_3 + 2NaCl$. Any peculiar advantage of the preparation must depend on the minute division of its particles. According to Dr. Bridges, this effect is best obtained by employing the solutions at the boiling temperature, a precaution which is observed in most processes now. (*A. J. P.*, xvi. 163.) When properly made, it is "a fine, white powder, without odor or taste, and permanent in the air. Nearly insoluble in water; the solubility is increased by the presence of ammonium salts, and especially by carbonic acid; alkaline hydrates diminish it. Insoluble in alcohol. In diluted acetic, hydrochloric, or nitric acid, it is completely soluble, with effervescence. When heated to redness with access of air, the salt loses carbon dioxide, and a residue of calcium oxide remains. For applying tests of identity and of purity, boil 6 Gm. of Calcium Carbonate with a mixture of 50 C.c. of diluted acetic acid and 50 C.c. of water, allow the liquid to cool, and filter. In this solution, ammonium oxalate test-solution produces a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If from 20 C.c. of this solution the calcium be completely precipitated by a slight excess of ammonium oxalate test-solution, the filtrate should, on evaporation, leave only a trace of fixed residue (limit of *magnesium* and *alkalies*). If 10 C.c. of the solution be slightly acidulated with acetic acid, no immediate turbidity should be produced by the addition of 0·5 C.c. of barium chloride test-solution (limit of *sulphate*). If to 10 C.c. of the

* "Take of Solution of Chloride of Calcium *five pints and a half;* Carbonate of Sodium *seventy-two troyounces;* Distilled Water *a sufficient quantity*. Dissolve the Carbonate of Sodium in six pints of Distilled Water. Heat this solution and the Solution of Chloride of Calcium, separately, to the boiling point, and mix them. After the precipitate has subsided, separate it from the supernatant liquid by decantation, and wash it with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver. Lastly, dry the precipitate on bibulous paper." *U. S.* 1870.

solution, slightly acidulated with nitric acid, 0·1 C.c. of silver nitrate volumetric solution be added, and the precipitate, if any, removed by filtration, the filtrate should remain perfectly clear upon addition of more silver nitrate volumetric solution (limit of *chloride*). Addition of ammonia water should not produce any turbidity in the solution (absence of *iron*, *aluminum*, *phosphate*, etc.). If to the solution, slightly acidulated with acetic acid, an equal volume of hydrogen sulphide test-solution be added, neither color nor turbidity should be produced (absence of *arsenic*, *lead*, etc.). If 1 Gm. of the salt be agitated with 50 C.c. of water, the filtrate should not show an alkaline reaction with litmus paper, and, on evaporation, should not leave more than a trace of residue (limit of *soluble impurities*)." *U. S.*

Medical Properties and Uses. For ordinary use, it probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness, but it is preferred by some in the preparation of tooth-powders. Dose, from 10 to 40 grains (0·65–2·6 Gm.) or more.

CALCII CHLORIDUM. U. S., Br. Calcium Chloride.

$CaCl_2$; 110·65. (KĂL'SĪ-Ī KLŌ'RĪ-DŬM.) $CaCl_2$; 110·8.

"Calcium Chloride, rendered anhydrous by fusion at the lowest possible temperature. It should be kept in well-stoppered bottles." *U. S.* "The salt, $CaCl_2,2H_2O$, formed by neutralizing hydrochloric acid with calcium carbonate, carefully desiccated at a temperature not exceeding 392° F. (200° C.)." *Br.*

Calcaria Muriatica, Chloridum Calcicum; Muriate of Lime, Hydrochlorate of Lime; Chlorure de Calcium, Hydrochlorate de Chaux, *Fr.*; Chlorcalcium, Salzsaures Kalk, *G.*

Calcium chloride consists of chlorine united with calcium, the metallic radical of lime. It may be readily formed by saturating hydrochloric acid with chalk or marble, evaporating to dryness, and heating to redness. The hydrochloric acid, by reacting with the lime, forms calcium chloride and water, the latter of which is dissipated at a red heat, $CaCO_3 + 2HCl = CaCl_2 + CO_2 + H_2O$. The Br. Pharm. (1885), after neutralizing the acid with calcium carbonate, adds a little solution of chlorinated lime and slaked lime, filters, evaporates till the chloride becomes solid, and, instead of igniting the residue, dries it at about 204·4° C. (400° F.). Its composition, according to the Br. Pharm., is $CaCl_2,2H_2O$.

Properties. Calcium chloride is in "white, slightly translucent, hard fragments, odorless, having a sharp, saline taste, and very deliquescent. Soluble, at 15° C. (59° F.), in 1·5 parts of water, and in 8 parts of alcohol; in 1·5 parts of boiling alcohol, and very freely in boiling water; insoluble in ether. Below a red heat the salt fuses, and, on cooling, solidifies without change in composition; but at a higher temperature, especially if kept in fusion for some time, a portion is decomposed and calcium oxide formed. When perfectly pure, the salt dissolves in water without residue, and the solution is strictly neutral to litmus paper. When the salt is overheated in fusing, the solution has an alkaline reaction, and a small residue is left, which is soluble in hydrochloric acid. The aqueous solution (1 in 20) yields, with ammonium oxalate test-solution, a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. With silver nitrate test-solution it yields a white precipitate insoluble in nitric acid. The aqueous solution (1 in 20) should remain clear upon addition of ammonia water (absence of *iron*, *aluminum*, etc.), or of barium chloride test-solution (absence of *sulphate*). If from 20 C.c. of the solution the calcium be completely precipitated by ammonium oxalate test-solution, the filtrate should, on evaporation, leave not more than a trace of fixed residue (limit of *magnesium* and *alkalies*). If 5 C.c. of the aqueous solution, acidulated with hydrochloric acid, be mixed with an equal volume of hydrogen sulphide test-solution, neither color nor turbidity should appear (absence of *arsenic*, *lead*, etc.). No turbidity should be produced by the addition of 0·5 C.c. of potassium dichromate test-solution to 5 C.c. of the aqueous solution (absence of *barium*)." *U. S.* "In dry, white, very deliquescent masses, soluble in an equal weight of *water* and in 3 parts of *alcohol* (90 per cent.). It affords the reactions characteristic of calcium and of chlorides. It should yield no characteristic reaction with the tests for iron, aluminium, or carbonates, and only the slightest reactions with the tests for magnesium. It evolves no chlorine or hypochlorous acid on the addition of *hydrochloric acid* (absence of hypochlorite)." *Br.* On account of its avidity for water, the fused salt is used for drying gases. The crystallized salt is also very deliquescent, and has the form of colorless, transparent, striated, six-sided prisms. The crystals, on exposure to heat, first dissolve in their water of crystallization, and, after this has evaporated, undergo igneous fusion. With ice or snow they form a powerful frigorific mixture. Calcium chloride exists in the water of the ocean and of many springs. It is usually associated with common salt and magnesium chlo-

ride, from which it is separated with difficulty. When crystallized it contains six molecules of water.

Medical Properties and Uses. According to A. E. Wright (*Brit. Med. Journ.*, 1891), calcium chloride when given internally increases the coagulability of the blood, and is probably a useful remedy in *hæmophilia*. Good results have been also claimed from it in *urticaria*, in *arthritis*, and in *rachitis*. According to Stefani (*Archiv. Ital. de Biolog.*, xxii., 1894), it has the property of conserving and re-establishing nervous excitability, and should be useful in conditions of *mental depression*. It may be given in doses of five grains (0·32 Gm.) three times a day, increasing if necessary to twenty grains (1·3 Gm.), in dilute solution.*

CALCII HYDRAS. Br. Calcium Hydroxide. Slaked Lime.

(KĂL'SĮ-Ī HĪ'DRĂS.)

"Calcium Hydroxide, $Ca(HO)_2$, recently prepared by the interaction of water and calcium oxide." *Br.*

Calcis Hydras; Hydrate of Lime.

The British Pharmacopœia no longer gives a detailed process for slaked lime. The process of the Br. Pharm. (1885) is as follows: "Take of Lime *two pounds* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Place the Lime in a metal pot, pour the water upon it, and when vapor ceases to be disengaged cover the pot with its lid and set it aside to cool. When the temperature has fallen to that of the atmosphere, put the slaked lime on an iron-wire sieve, and by gentle agitation cause the fine powder to pass through the sieve, rejecting what is left. Put the powder into a well-stoppered bottle, and keep it excluded as much as possible from the air. Slaked lime should be recently prepared." Calcium hydroxide "affords the reactions characteristic of calcium. Strongly heated it loses nearly one-fourth of its weight of water. It should yield only the slightest characteristic reactions with the tests for iron, aluminium, magnesium, sodium, potassium, carbonates, chlorides, phosphates, sulphates, or silica." *Br.*

For an account of the physical and medical properties of slaked lime, see *Calx*.

CALCII HYPOPHOSPHIS. U. S., Br. Calcium Hypophosphite.

$Ca(PH_2O_2)_2$; 169·67. (KĂL'SĮ-Ī HĪ-PŌ-PHŎS'PHĮS.) $CaH_4(PO_2)_2$; 170.

Calcis Hypophosphis; Hypophosphite of Lime; Calcaria Hypophosphorosa, Hypophosphis Calcicus; Hypophosphite de Chaux, *Fr.*; Unterphosphorigsaurer Kalk, *G.*

"Calcium Hypophosphite, $Ca(PH_2O_2)_2$, is obtained by the interaction of phosphorus, calcium hydroxide, and water." *Br.*

Attention has been called to the hypophosphites as a class of salts, in consequence of their recommendation by Dr. Churchill, of Paris, in the treatment of *phthisis*, in which they are thought to be useful by furnishing phosphorus to the tissues. One of the first papers on their mode of preparation and qualities was communicated by Prof. Procter. (See *A. J. P.*, xxx. 118.) Hypophosphorous acid consists of one atom of phosphorus, two of oxygen, and three of hydrogen, of which latter, however, only one is replaceable by metal. It is, therefore, a monobasic acid. It has a strong affinity for oxygen, and acts as a powerful deoxidizing or reducing agent, which property it is supposed to owe to the presence of the unreplaceable hydrogen atoms, sometimes termed "aldehydic" hydrogen. When heated, it is resolved into hydrogen phosphide and phosphoric acid. Its salts are generally soluble in water and deliquescent, and many of them are soluble in alcohol. They are converted into phosphates by heat, with the escape of hydrogen phosphide; and some of them are explosive.

Calcium hypophosphite has attracted most attention, and would meet the views of those who wish to supply calcium phosphate to the system, as the hypophosphorous acid is converted into the phosphoric by its deoxidizing power. To prepare it Prof. Procter gave the following formula. Slake 4 pounds (avoirdupois) of lime with a gallon of water, add it, in a deep boiler, to 4 gallons of boiling water, and mix thoroughly. To the mixture add a pound (av.) of phosphorus, and continue the boiling, adding hot water from time to time to keep up the measure, until the combination is complete, and phosphuretted hydrogen is no longer evolved. It is necessary that provision should be made for the escape of the gas, which takes fire spontaneously in contact with the air. There are formed in the liquid calcium phosphate and hypophosphite, the phosphorus having become oxidized at the expense of the water, the

* *Liquor Calcii Chloridi* was official in U. S. Pharm. 1870. A convenient method of making this preparation is to dissolve 228 grains of fused calcium chloride in 1 fluidounce of distilled water, and filter if necessary.

hydrogen of which has escaped in combination with another portion of phosphorus, which is therefore lost. The liquid is filtered to separate the insoluble phosphate and residuary lime, then concentrated, and refiltered to separate the calcium carbonate formed by the action of the air on a little lime held in solution, and lastly evaporated till a pellicle appears; after which the salt may be allowed to crystallize by setting the liquid aside, or may be obtained in the granular form by continuing the heat, and stirring. The salt should be introduced into bottles. The British Pharmacopœia has practically adopted this process, but any uncombined lime remaining in the solution is separated by passing carbonic acid gas through it.

Calcium hypophosphite is in "colorless, transparent, monoclinic prisms, or small, lustrous scales, or a white, crystalline powder, odorless, having a nauseous, bitter taste, and permanent in the air. Soluble, at 15° C. (59° F.), in 6·8 parts of water, and in 6 parts of boiling water; insoluble in alcohol. When heated in a test-tube, the salt decrepitates, and above 300° C. (572° F.) it begins to decompose, giving off water, and emitting inflammable gases (hydrogen and hydrogen phosphide), and leaving a residue of calcium pyrophosphate and metaphosphate, with some red phosphorus. The aqueous solution (1 in 20) is neutral to litmus paper, and yields, with ammonium oxalate test-solution, a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. The aqueous solution, slightly acidulated with sulphuric acid, yields, with silver nitrate test-solution, a precipitate which is white at first, but rapidly turns brown and black by separation of metallic silver. With copper sulphate test-solution, on gentle heating, a reddish-brown precipitate of copper hydride is formed. When the aqueous solution is added, drop by drop, to mercuric chloride test-solution, at first a white precipitate of mercurous chloride is formed, which, as soon as the hypophosphite solution is added in excess, turns gray from reduction to metallic mercury. If 1 Gm. of the salt be dissolved in 20 C.c. of water, no insoluble residue should be left (absence of *phosphate*, *sulphate*, and other *insoluble impurities*). In this solution no precipitate should be produced by the addition of lead acetate test-solution (absence of *soluble phosphate*); nor, after acidulating with hydrochloric acid, by barium chloride test-solution (absence of *soluble sulphate*); nor by an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, etc.). On adding to 5 C.c. of the solution (1 in 20) 1 C.c., each, of ammonium chloride test-solution and ammonia water, and 3 C.c. of ammonium carbonate test-solution, applying a gentle heat for a few minutes, and then filtering, not more than a very slight turbidity should be produced upon adding to the filtrate a few drops of sodium phosphate test-solution (limit of *magnesium*). If 0·1 Gm. of the salt be dissolved in 10 C.c. of water, then mixed with 10 C.c. of sulphuric acid and 50 C.c. of potassium permanganate decinormal volumetric solution, and the mixture boiled for fifteen minutes, it should require not more than 3 C.c. of oxalic acid decinormal volumetric solution to discharge the red color (corresponding to at least 99·68 per cent. of the pure salt)." *U. S.* "Soluble in 8 parts of cold *water;* insoluble in cold *alcohol* (90 per cent.). Heated to redness the crystals ignite, evolving spontaneously inflammable hydrogen phosphide and hydrogen, and leave a reddish-colored residue. It affords the reactions characteristic of calcium. Its aqueous solution yields with *test-solution of mercuric chloride* a white precipitate turning gray. 0·25 gramme boiled for ten minutes with a solution of 0·6 gramme of *potassium permanganate* should yield, on filtration, a nearly colorless solution. The salt should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, magnesium, sodium, or potassium, and only the slightest reactions with the tests for chlorides or sulphates. It should afford little or no precipitate with *solution of lead acetate* (limit of phosphates and phosphites)." *Br.* The solubility of calcium hypophosphite is increased by the addition of hypophosphorous acid. For a method of purifying alkaline hypophosphites, see *Journ. de Pharm. d'Anvers*, 1879, 57; *N. R.*, 1879, 142.

As the soluble salts of mercury, copper, and silver are reduced by the hypophosphites, they are of course incompatible with it in prescriptions. With calcium hypophosphite all the soluble sulphates and carbonates produce precipitates. As the hypophosphites are insoluble in cod-liver oil, they should be dissolved in syrup before being added to the oil. (See *Syrupus Calcii Hypophosphitis.*) W. A. H. Naylor considers the presence of sulphites in commercial hypophosphites to be the source of the disagreeable odor of sulphuretted hydrogen sometimes found in the compound syrup of hypophosphites. (*P. J. Tr.*, 1895, 144.)

Medical Properties and Uses. Calcium hypophosphite has been with the other hypophosphites strongly recommended in *chronic phthisis*, and is still much used; but the weight of testimony appears to be opposed to the first favorable impressions; and, though some cases may have seemed to be benefited, yet great care must be taken not to allow a reliance on the

hypophosphites to interfere with the use of remedies known to be efficient, as cod-liver oil, and supporting measures generally. The remedy has also been highly recommended in *scrofulous diseases* and in cases of defective nutrition of the nerve-centres; but in most of these latter cases some direct preparation of phosphorus is probably superior, as it is not proved and not probable that the hypophosphites can yield up their phosphorus to the nerve-centres. Dose, from ten to thirty grains (0·65–1·95 Gm.), three times a day. (See *Syrupus Hypophosphitum.*)

CALCII PHOSPHAS PRÆCIPITATUS. U. S. (Br.) Precipitated Calcium Phosphate.

$Ca_3(PO_4)_2$; 309·33. (KAL'SI-Ī FŌS'FĂS PRÆ-SĬP-I-TĀ'TŬS.) $Ca_3(PO_4)_2$; 310.

"Calcium Phosphate may be prepared by dissolving bone ash in dilute hydrochloric acid, adding the liquid to dilute solution of ammonia, washing the precipitate with cold water, and drying the washed precipitate at a temperature not exceeding 212° F. (100° C.); or by the interaction of calcium chloride and sodium phosphate." *Br.*

Calcii Phosphas, *Br.*, Calcis Phosphas (1885), Calcium Phosphate; Phosphate of Calcium; Calcaria Phosphorica, *P. G.;* Phosphas Calcicus Præcipitatus; Precipitated Phosphate of Lime; Phosphate de Chaux hydraté, *Fr.;* Phosphorsaure Kalkerde, *G.*

A formula for this preparation was given in the U. S. Pharmacopœia of 1870.* It has been very properly retained in the U. S. and Br. Pharmacopœias. There is, however, no necessity of retaining the word "præcipitatus" in the U. S. title, as it is never seen in commerce except as a precipitate. One of its more recent uses is to replace magnesium carbonate and absorbent cotton in the process for medicated waters.

The hydrochloric acid dissolves the calcium phosphate of the bones, and lets it fall, on the addition of ammonia, in a state of minute division. The ablution is intended to free it from adhering ammonium chloride. The salt thus obtained is, for the sake of distinction, called *bone calcium phosphate.* It is "a light, white, amorphous powder, odorless and tasteless, and permanent in the air. Almost insoluble in cold water; partly decomposed by boiling water, which dissolves out an acid salt; almost insoluble in acetic acid, except when freshly precipitated; easily soluble in hydrochloric or nitric acid; insoluble in alcohol. At an intense, white heat the salt fuses without decomposition. When moistened with silver nitrate test-solution, a yellow color is assumed by the salt either before or after ignition (distinction from *acid calcium phosphate*, which, after ignition, when moistened with silver nitrate, remains white). For applying tests of identity and purity, shake 2 Gm. of the salt with 20 C.c. of water and add nitric acid, drop by drop, until solution is effected; then add water to make the liquid measure 40 C.c. No effervescence should occur on adding the acid (absence of *carbonate*). From a portion of this solution the salt is precipitated unchanged by a slight excess of ammonia water. From another portion ammonium molybdate test-solution precipitates yellow ammonium phosphomolybdate; the reaction is accelerated by a gentle heat. If to 5 C.c. of the solution, acidulated with nitric acid, 0·5 C.c. of silver nitrate test-solution be added, not more than a slight turbidity should result (limit of *chloride*). The clear solution should not be rendered turbid by barium chloride test-solution (absence of *sulphate*); nor by potassium sulphate test-solution (*barium*); nor by an equal volume of hydrogen sulphide test-solution (*arsenic, lead*, etc.); nor should it be colored blue by potassium ferrocyanide test-solution (*iron*). If 5 C.c. of the solution be mixed with 1 C.c. of sodium acetate test-solution, and then with ammonium oxalate test-solution, until the calcium is completely precipitated, the filtrate should not be rendered very turbid by adding ammonia water in slight excess (limit of *magnesium*)." *U. S.* "Soluble in *diluted hydrochloric acid* or *diluted nitric acid;* such a solution continues clear when a dilute solution of *sodium acetate* is added in excess (absence of calcium oxalate). It affords the reactions characteristic of calcium and of phosphates. Of the recently dried powder, 1 gramme dissolved in *diluted hydrochloric acid* yields, when added to a very slight excess of *diluted solution of ammonia*, a white precipitate weighing when washed with cold

* "Take of Bone, calcined to whiteness, and in fine powder, *four troyounces;* Muriatic Acid *eight troyounces;* Water of Ammonia *twelve fluidounces*, or *a sufficient quantity;* Distilled Water *a sufficient quantity.* Macerate the Bone in the Acid, diluted with a pint of Distilled Water, until it is dissolved, and filter the solution. Add another pint of Distilled Water, and then, gradually, Water of Ammonia, until the liquid acquires an alkaline reaction. Mix the precipitate obtained, while yet in the state of magma, with twice its bulk of boiling Distilled Water, and pour the whole upon a strainer. Wash the precipitate with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver, acidulated with nitric acid. Lastly, dry the precipitate with a gentle heat." *U. S.* For description of an apparatus for preparing calcium phosphate on a large scale, see *Journ. de Pharm.*, Sept. 1, 1875, 193.

water and dried at 212° F. (100° C.) not less than 0·95 gramme. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, magnesium, carbonates, or silica, and only the slightest reactions with those for chlorides." *Br.* Joly and Sorel record (*Compt.-Rend.*, 1894, 738) the precipitation of tricalcium phosphate by adding crystals of hydrated bicalcium phosphate to boiling water; the acid liquid remaining contains monocalcium phosphate.

Medical Uses. In the form of burnt hartshorn, calcium phosphate formerly enjoyed a brief popularity in the treatment of *rickets* and *mollities ossium*, in which its use seemed to be indicated upon obvious chemical grounds. In 1851, Benecke suggested that, as it is essential in animals as well as plants to the formation of cells, it might be found useful in certain pathological states of the system characterized by defective nutrition, such as the *scrofulous affections*, and from that time its use has gradually become more frequent, and, in connection with other phosphates, as those of iron, sodium, and potassium, it has acquired no little reputation in different forms of *scrofula*, *mollities ossium*, *rickets*, and even *chronic phthisis*. It is also thought to have proved useful by hastening the *union of fractured bones;* and M. Alphonse Milne-Edwards is said to have shown, by experiments upon dogs and rabbits, that in these animals the callus in fractured bones forms more quickly under its use than without it. (*Med. Times and Gaz.*, May, 1856, p. 489.) Though insoluble in water, it is probably in general dissolved by the gastric liquids, in consequence of the acid present in them; but it is best administered in acid solution, and is at present very extensively used dissolved in lactic acid and emulsified with cod-liver oil. The dose is from ten to thirty grains (0·65–1·95 Gm.). (See *Syrupus Calcii Lactophosphatis;* also *Pulvis Antimonialis.*)

CALCII SULPHAS EXSICCATUS. U. S. Dried Calcium Sulphate.

[Dried Gypsum. Plaster of Paris.]

(CĂL'CI-Ī SŬL'PHĂS ĔX-SIC-CĀ'TŬS.)

"A powder containing about 95 per cent., by weight, of Calcium Sulphate [$CaSO_4 = 135·73$], and about 5 per cent. of Water; prepared from the purer varieties of Native Gypsum [$CaSO_4 + 2H_2O = 171·65$], by carefully heating until about three-fourths of the water has been expelled. Dried Calcium Sulphate should be kept in well-closed vessels, carefully protected from moisture." *U. S.*

Sulphate of Calcium; Calcis Sulphas; Sulphate of Lime; Gypsum.

The British Pharmacopœia (1898) dismissed calcium sulphate (dried), but inserted calcium sulphate in the articles employed in chemical testing in the Appendix. The native sulphate is best known as *gypsum*, and in its massive variety as *alabaster*. Gypsum is an abundant natural product, the quantity mined in the United States in 1896 having been 195,553 short tons, valued at $583,136; and in 1897, 223,061 short tons, valued at $711,952. It is officially described "as a fine white powder, without odor or taste. From moist air it attracts water, becomes granular, and then loses the property of hardening with water. When mixed with half of its weight of water, Dried Calcium Sulphate forms a smooth, cohesive paste, which rapidly hardens. It is soluble in about 410 parts of water, at 15° C. (59° F.); in 388 parts, at 38° C. (100·4° F.); and in 476 parts, at 100° C. (212° F.). In alcohol it is insoluble. It readily dissolves in diluted nitric or hydrochloric acid, also in saturated solutions of potassium nitrate, sodium hyposulphite, and of various ammonium salts. When heated above 204° C. (399·2° F.), Dried Calcium Sulphate becomes anhydrous and loses the property of forming a paste with water and hardening rapidly. Its saturated solution in water should be neutral to litmus paper. It forms white precipitates with barium chloride test-solution, with ammonium oxalate test-solution, and with alcohol. No effervescence should occur on the addition of diluted acids to Dried Calcium Sulphate (absence of *carbonate*)." *U. S.*

Medical Properties and Uses. Gypsum is used by surgeons for mechanical purposes, and not at all in internal medicine. It is so slightly soluble in water that it may be considered for ordinary purposes insoluble. The solubility of the crystallized sulphate with 2 molecules of water (native gypsum) is, according to Curtman, at 15° C., 1 to 390; at 38° C., 1 to 368; and at 100° C., 1 to 451. The fact has been well established that its solubility varies with the temperature, but, like that of sodium sulphate, very unequally. Thus, according to M. Poggiale, it is greatest at 35° C. (95° F.), and above or below that temperature gradually diminishes, so that at 100° C. (212° F.), or the boiling point of water, it is very nearly the same as at 5° C. (41° F.), not far from the freezing point. (*Journ. de Pharm.*, 4e sér., v. 86.)

The other point is that, when deprived of its water by heat, and reduced to the state of a white powder, it rapidly absorbs water added to it, and, from the state of semi-liquid paste into which it is brought with that fluid, hardens without great change of bulk. It is this property which fits plaster of Paris so well for all kinds of moulding; and to this also it owes its peculiar adaptability to the purpose of a splint. To prepare it for use, the gypsum must first be deprived of the greater part of its water by exposure to a heat of 100° C. (212° F.), or from that to 121·1° C. (250° F.). It loses both its molecules of water of crystallization at a temperature of about 170° C. (338° F.), and is then known as *burnt gypsum*. If heated above 204° C. (399·2° F.) it becomes *dead-burnt*, and does not take up water readily and does not harden. When dehydrated, it is reduced to fine powder, and kept in air-tight vessels for use. As thus prepared, if mixed with two parts of water, it forms a semi-liquid cream-like mass, which becomes solid and hard in fifteen or twenty minutes, the temperature rising during the process, as in the slaking of lime. The hydrated gypsum expands in solidifying, hence its advantages in preparing casts,—the expansion causes it to fill accurately all interstices. According to Mr. T. E. Stark, a medical officer in the British army, flannel is the best material for bandages to be used with gypsum. It should be cut into strips an inch and a half broad and two or three yards long, which should first be spread on a table and rubbed well with the powdered gypsum on both sides, and always in the direction of the thread. The bandages should then be rolled up loosely, and kept for use in air-tight cases. Thus applied, the bandages, first thoroughly wetted, should be rolled round the limb, overlapping at the edges, so as to make a uniform covering. After application, it should be left to harden, which generally happens in fifteen or twenty minutes. A simpler method of using the gypsum for this purpose is, after the application of the bandages, to paint the whole thoroughly and carefully with the milk of gypsum, which will solidify, and enclose the part in a firm case.

CALENDULA. U. S. Calendula. [Marigold.]

(CA-LĔN'DŬ-LA.)

"The florets of Calendula officinalis, Linné (nat. ord. Compositæ)." *U. S.*

Fleurs de Tous les mois, Souci, *Fr.;* Ringelblume, *G.*

Gen. Ch. Flower-head heterogamous, rayed, with the female flowers of the ray fertile, in one or two rows, the hermaphrodite of the disk sterile. *Involucre* broad, with linear, acuminate, subequal, often scarious bracts in one or two rows. *Receptacle* flat, naked. *Corolla* of female flowers ligulate, with the lamina entire or three-dentate. Hermaphrodite flowers, regular, tubular, with an enlarged limb shortly five-cut at the apex. *Anthers* sagittate, with the auricles setaceous-mucronate or caudate. *Style* of the hermaphrodite flower undivided. *Achenia* bare; those of the ray incurved, 2–3-serrate, heteromorphous usually upon the back, or everywhere muricate; the outer often elongate, linear, sometimes empty; the intermediate broader, often alate; the interior shorter, more incurved; those of the disk thin, smooth, empty. (Bentham and Hooker, *Genera Plantarum*, ii. 454.)

Calendula officinalis. L. The common marigold of the gardens is too well known to need description, other than that of the Pharmacopœia.

Properties. "Florets about 12 Mm. long, linear and strap-shaped, delicately veined in a longitudinal direction, yellow or orange-colored, three-toothed above, the short hairy tube enclosing the remnants of a filiform style terminating in two elongated branches; odor slight and somewhat heavy; taste somewhat bitter and faintly saline." *U. S.* The odor is much stronger in the fresh than in the dry herb, and on exposure to the sun the yellow color fades into whitish. Among its constituents is a peculiar principle, called *calendulin*, discovered by Geiger most abundantly in the flowers, and considered by Berzelius as analogous to bassorin, though soluble in alcohol. *French* or *African Marigold*, so called, is very frequently substituted for the official drug. It is the *Tagetes patula* L. and *T. erecta* Lin., both of Mexico. The flowers are readily distinguished by the scales of the involucre being united to form a tube, and by the slender, flattish achenes being crowned with a few chaffy or awned scales. The broadly strap-shaped ray-florets are toothed, and of a light or deep orange color sometimes striped with red.

Medical Properties and Uses. In the days of therapeutic darkness calendula was thought to be antispasmodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of *fever*, *scrofula*, *jaundice*, *amenorrhœa*, etc. Both the leaves and the flowers were used; but the latter were preferred, and were usually administered in the recent state in the form of tea. An extract was also prepared, and employed in *cancerous* and other *ulcers*, *sick stomach*,

etc. The tincture has been used to a considerable extent as an embrocation in sprains, bruises, etc., and probably is of as much value as simple alcohol.

CALUMBA. U. S. (Br.) Calumba. [Columbo]

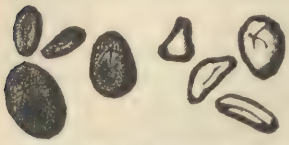
(CA-LŬM'BA.)

"The root of Jateorhiza palmata (Lamarck), Miers (nat. ord. Menispermaceæ)." *U. S.*
"The dried transversely cut slices of the root of Jateorhiza Columba, Miers." *Br.*

Calumbæ Radix, *Br.*, Calumba Root; Radix Colombo, *P. G.*; Radix Columbo; Colomba, *U. S.* 1850; Colombo, *Fr.*; Columbowurzel, *G.*; Columba, *It.*; Raiz de Columbo, *Sp.*; Kalumbo, *Port.*; Calumb, *Mozambique.*

The columbo plant was long but imperfectly known. Flowering specimens of a plant gathered by Commerson, about the year 1770, in the garden of M. Poivre in the Isle of France, and sent to Europe with that botanist's collection, were examined by Lamarck, and described under the name of *Menispermum palmatum.* But its original locality was unknown, and it was only conjectured to be the source of columbo. In the year 1805, M. Forten, while engaged in purchasing the drug in Mozambique, obtained possession of a living offset of the root, which, being taken to Madras and planted in the garden of Dr. Anderson, produced a male plant, which was figured and described by Dr. Berry. From the drawing thus made, the plant was referred to the natural family of the Menispermaceæ; but, as the female flowers were wanting, some difficulty was experienced in fixing its precise botanical position. De Candolle, who probably had the opportunity of examining Commerson's specimens, gave its generic and specific character, but confessed that he was not acquainted with the structure of the female flower and fruit. This desideratum, however, was supplied by ample drawings sent to England by Mr. Telfair, of Mauritius, made from plants which were propagated from roots obtained by Captain Owen in 1825, while prosecuting his survey of the eastern coast of Africa. The plant was first placed in the genus Cocculus, which was separated by De Candolle from Menispermum. Subsequently, J. Miers established a new genus, which has been received by botanists, giving to it the name of Jateorhiza. Miers also separated his plant specifically from *C. palmatus* of De Candolle, describing it under the name of *Jateorhiza columba.* This species is now recognized by the Br. Pharmacopœia, and was formerly also acknowledged by the U. S. Pharmacopœia. But the very careful researches of Mr. Hanbury (*Pharmacographia*, 2d ed., p. 23) led him to consider the specific differences as unimportant and inconstant, with which view the botanists of the U. S. 1890 revision coincided. The differences are that in *J. palmata* "the lobes at the base of the leaf overlap, and the male inflorescence is nearly glabrous; while in *J. columba* the basal lobes are rounded, but do not overlap, and the male inflorescence is setose-hispid." The plants are probably only varieties of one species, and it is almost certain that columbo is derived from each of them.

Gen. Ch. Sepals 6, in two rows, somewhat unequal, thin. *Petals* 6, shorter than the sepals. Male flowers: *Stamens* 6, free, with the apex recurved-clavate. *Anthers* unilocular, with the apex extrorse, dehiscent by a transverse cleft. Female flowers: *Carpels* 3, with lacerate, reflex stigmata. *Drupe* ovoid, with a subterminal cicatrix of the style. *Putamen* somewhat concave in its inner face. *Seed* meniscoid; albumen fleshy, ruminate; embryo somewhat curved. *Cotyledons* laterally bivaricate." (Bentham and Hooker, *Genera Plantarum*, i. 34.)



"The plants of this genus, natives of intertropical Africa, are all climbers, distinguished by a very peculiar habit, having very large deeply-lobed leaves, upon very long petioles, and clothed with long strigose hairs; their inflorescence is in long slender racemes; the fruit is a drupe containing a putamen covered with a dense hairy coating embedded in the fleshy mesoderm."

Cocculus palmatus. De Cand. *Syst. Veg.* i. 523; Woodv. *Med. Bot.*, 3d ed., v. 21; Hooker, *Curtis's Bot. Mag.*, Nos. 2970, 2971.—*Jateorhiza palmata.* Miers, *Annals and Mag. of Nat. Hist.*, Feb. 1864, p. 183. *B. & T.* 13. This is a climbing plant, with a perennial root consisting of several fasciculated, fusiform, somewhat curved, and descending tubers, as thick as an infant's arm. The stems, of which one or two proceed from the same root, are twining, simple in the male plant, branched in the female, round, hairy, and about as thick as the little finger. The leaves, which stand on rounded, glandular, hairy footstalks, are alternate, distant, cordate, with three, five, or seven entire, acuminate, wavy, somewhat hairy lobes, and as many nerves, each running into one of the lobes. The flowers are small and inconspicuous, and arranged in solitary axillary racemes, which in the male plant are compound, in the female simple, and in both shorter than the leaves.

Jateorhiza columba. Miers. Br. Pharm.—*Cocculus palmatus.* Wallich, non De Cand.—*Menispermum calumba.* Roxb. *Flor. Ind.* This species is characterized by "rounded, angularly striate, roughly pilose branches; broadly orbicular, sinuously lobed leaves, with rounded sinuses;

the lobes being 5 in number, broadly ovate, acute, mucronately acuminate; the basal deeply divaricate and hence broadly cordate; 7 to 9 nerved, opaque above, on both sides furnished with short, adpressed, somewhat curved, reddish hairs, beneath, pale, strongly reticulate with prominent nerves and veins; the petiole somewhat slender, striate, tortuous, and roughly glandular; the racemes axillary, solitary or many; the rachis greatly elongated, striate, bristly, with elongated, smooth, divaricate, almost capillary, subflexuous, few-flowered branches; the flowers sessile, and almost without bracts." (*Miers.*)

Both of these so-called species are natives of Mozambique, on the southeastern coast of Africa, where they grow wild in great abundance in the thick forests extending from the sea many miles into the interior. They are not cultivated. The root is dug up in March, when dry weather prevails. From the base of the root numerous fusiform offsets proceed, less fibrous and woody than the parent stock. These offsets are separated and cut into transverse slices, which are dried in the shade. The old root is rejected.

Magnified starch granules of columbo root.

Columbo is a staple export of the Portuguese from their dominions in the southeast of Africa. It is taken to India, and thence distributed. It was formerly supposed to be a product of Ceylon, and to have derived its name from Colombo, a city of that island, from which it was thought to be exported. It is possible that, when the Portuguese were in possession of Ceylon, Colombo may have been the entrepôt for the drug brought from Africa, and thus have given origin to its name. Some, however, consider a more probable derivation to be from the word *calumb*, which is said to be the Mozambique name for the root.

Properties. "In nearly circular disks, 3 to 6 Cm. in diameter, externally greenish-brown and wrinkled, internally yellowish or grayish-yellow, depressed in the centre, with a few interrupted circles of projecting wood-bundles, distinctly radiate in the outer portion; fracture short, mealy; odor slight; taste mucilaginous, slightly aromatic, very bitter." *U. S.* Along with the disks are sometimes a few cylindrical pieces an inch or two in length. The cortical portion is thick, of a bright yellow, slightly greenish color internally, but covered with a brownish, wrinkled epidermis. The interior or medullary portion, which is readily distinguishable from the cortical, is light, spongy, yellowish, usually more or less shrunk, so that the pieces are thinnest in the centre; and is often marked with concentric circles and radiating lines. Those pieces are to be preferred which have the brightest color, are most compact and uniform, and least worm-eaten. "The cork is brownish and wrinkled, the cortex thick, marked with radiating lines, and separated by a dark line from the wood, in which the vessels are arranged in narrow radially elongated groups. The parenchymatous tissue is largely developed, and contains numerous starch grains, mostly simple with eccentric hilum." *Br.* The odor of columbo is slightly aromatic. The taste is very bitter, that of the cortical much more so than that of the central portion, which is somewhat mucilaginous. The root is easily pulverized. The powder is greenish, becoming browner with age, and deepening when moistened. As it attracts moisture from the air, and is apt to undergo decomposition, it should be prepared in small quantities.

M. Planche analyzed columbo in 1811, and found it to contain a nitrogenous substance, probably albumen, in large quantity, a bitter yellow substance not precipitated by metallic salts, and one-third of its weight of starch. He obtained also a small proportion of volatile oil, salts of lime and potassa, ferric oxide, and silica. Wittstock, of Berlin, afterwards isolated a principle, which he called *columbin*. This crystallizes in beautiful transparent quadrilateral prisms of the formula $C_{21}H_{22}O_7$, is without smell, and is extremely bitter. It is but very slightly soluble in water, more soluble in alcohol, ether, or chloroform, and imparts to these fluids a strongly bitter taste. It is more soluble in boiling alcohol, which deposits it upon cooling. The best solvent is dilute acetic acid. It is taken up by alkaline solutions, from which it is precipitated by acids. It has neither acid nor alkaline properties, and its alcoholic and acetic solutions are not affected by the metallic salts, or by the infusion of galls. It is obtained by exhausting columbo by means of alcohol of the sp. gr. 0·835, distilling off three-quarters of the alcohol, allowing the residue to stand for some days till crystals are deposited, and lastly treating these crystals with alcohol and animal charcoal. The mother-waters still contain a considerable quantity of columbin, which may be separated by evaporating with coarsely-powdered glass to dryness, exhausting the residue with ether, distilling off the ether, treating the residue with boiling acetic acid, and evaporating the solution to crystallization.

From the researches of Dr. Bödecker it appears that another bitter principle exists in columbo, which corresponds in composition and chemical relations with *berberine*, the active principle of *Berberis vulgaris*, and is assumed to be identical with that substance. It was obtained by exhausting columbo with alcohol of 0·889, distilling off the alcohol, allowing the residual liquor to stand for three days so as to deposit the columbin, evaporating the supernatant liquid together with the aqueous washings of the columbin to dryness, exhausting the residue with boiling alcohol of 0·863, treating the solution thus obtained as the former one, submitting the residue to the action of the boiling water, filtering, and adding hydrochloric acid, collecting the precipitate thus formed on a filter, drying it with bibulous paper, and finally, in order to separate adhering acid, dissolving it in alcohol, and precipitating with ether. The result was an imperfectly crystalline, bright yellow powder, of a disagreeable, bitter taste, supposed to be *berberine hydrochlorate*. It is stated that berberine is present in columbo in much larger proportion than columbin, and, being freely soluble in hot water and alcohol, while columbin is but slightly so, is probably more largely extracted in the ordinary liquid preparations of the root. (*A. J. P.*, xx. 322.) A third constituent, *columbic acid*, was also discovered by Bödecker. It is yellow, amorphous, nearly insoluble in cold water, but dissolving in alcohol and in alkaline solutions. It tastes somewhat less bitter than *columbin*. Bödecker surmises that it may exist in combination with the berberine, and has pointed out a connection between the three bitter principles of columbo. If we suppose a molecule of ammonia, NH_3, to be added to two molecules of *columbin*, $C_{21}H_{22}O_7$, the complex molecule thus resulting will contain the elements of *berberine*, $C_{20}H_{17}NO_4$, *columbic acid*, $C_{22}H_{24}O_7$, and water, $3H_2O$. (*Pharmacographia*, p. 25.)

P. E. Alessandri isolated *calumbine*, which he considers an alkaloid, by the following process. An infusion of columbo is made with a 3 per cent. solution of oxalic acid; the yellow bitter liquid is neutralized with ammonia and evaporated to one-third its bulk; it is, when cooled, treated with ether, separated, and the ethereal solution on evaporation yields pure white calumbine. (*L'Orosi*, v. 1; *P. J. Tr.*, 1882, p. 995.) Alessandri obtains *berberine* from columbo by neutralizing a cold infusion, made with diluted oxalic acid (3 per cent.), with baryta; the precipitate which is produced is separated. The liquid is heated, allowed to stand for twenty-four hours to allow the barium oxalate to deposit, filtered, and then a current of carbonic acid is passed through to remove baryta. It is then treated by shaking the ammoniacal liquid with ether as in Alessandri's process for calumbine (see above), and, after the ethereal layer is separated, the aqueous liquid is evaporated to dryness. Berberine is obtained from the extract by treating the latter with alcohol, the berberine being purified by washing with ether. *Calumbic acid* may be obtained from the precipitate produced by the addition of baryta to the oxalic acid infusion. (*L'Orosi*, v. 1; *P. J. Tr.*, 1882, p. 995.) Bocchiola (*Year-Book of Pharmacy*, 1891, p. 162) states that the older roots contain more of the active principles than the younger ones. He found that the inner and the outer portions of columbo also vary in their constituents; thus, in the woody or inner part he found the following percentages: calumbine 1.90, berberine 0·72, ether extract 0·80, alcoholic extract 3·86, diluted alcoholic extract 17·80, ash 6. In the cortical or outer part he found calumbine 1·42, berberine 1·43, ether extract 0·70, alcoholic extract 3·89, diluted alcoholic extract 17·96, ash 5. Hilger obtained from columbo columbin, columbic acid, and berberine in a pure condition. He assigns to columbin the formula $C_{21}H_{24}O_7$, and to columbic acid $C_{21}H_{22}O_6$. (*Zeitschr. Oest. Apoth. Ver.*, 1896, No. 1, 8–14.)

There can be little doubt that both columbin and berberine contribute to the remedial effects of columbo. The virtues of the root are extracted by boiling water and by alcohol. Precipitates are produced with the infusion and tincture by infusion of galls, and by solutions of lead acetate and subacetate, but the bitterness is not affected.

Adulterations. It is said that the root of *white bryony*, tinged yellow with the tincture of columbo, has sometimes been fraudulently substituted for the genuine root; but the adulteration is too gross to deceive those acquainted with the characters of either of these drugs. American columbo, which is the root of *Frasera walteri*, is said to have been sold in some parts of Europe for the genuine. Independently of the sensible differences between the two roots (see *Frasera*), M. Stolze, of Halle, states that, while the tincture of columbo remains unaffected by ferric sulphate or sesquichloride, and gives a dirty-gray precipitate with tincture of galls, the tincture of frasera acquires a dark green color with the former reagent, and is not affected by the latter. (*Duncan.*) Under the name of *columbo wood*, or *false columbo*, the wood of *Coscinium fenestratum*, a plant of the family of Menispermaceæ, growing in Ceylon,

has been imported into England and offered for sale in the drug market. (*P. J. Tr.*, x. 321, xii. 185.)

Medical Properties and Uses. Columbo is among the most useful of the mild tonics. Without astringency, with very little stimulating power, and generally acceptable to the stomach, it answers admirably as a remedy in simple *dyspepsia*, and in the *debility* of convalescence, especially when the alimentary canal is left enfeebled. Hence it is often prescribed in the declining stages of *remittent fever*, *dysentery*, *diarrhœa*, *cholera morbus*, and *cholera infantum*. The absence of irritating properties renders it also an appropriate tonic in the hectic fever of *phthisis* and kindred affections. It has been highly recommended in *vomiting* unconnected with inflammation of the stomach, as in the sickness of pregnant women. It is frequently administered in combination with other tonics, aromatics, mild cathartics, and antacids. A favorite remedy of Dr. Geo. B. Wood for the permanent cure of a disposition to the accumulation of *flatus* in the bowels was an infusion made with half an ounce of columbo, half an ounce of ginger, a drachm of senna, and a pint of boiling water, and given in the dose of a wineglassful three times a day. Columbo is much used by the natives of Mozambique in *dysentery* and other diseases. (*Berry.*) It was first introduced to the notice of the profession in Europe by François Redi, in the year 1685. It is most commonly prescribed in the state of infusion. (See *Infusum Calumbæ;* also *Extractum Calumbæ Fluidum*, and *Tinctura Calumbæ.*) The dose of the powder is from ten to thirty grains (0·65–1·95 Gm.), and may be repeated three or four times a day.

CALX. U. S., Br. Lime.

Ca O; 55·87. (CĂLX.) Ca, O; 56.

"Lime prepared by burning white marble, oyster-shells, or the purest varieties of natural calcium carbonate. It should be kept in well-closed vessels, in a dry place." *U. S.* "Calcium oxide, CaO; obtained by calcining chalk, limestone, or marble." *Br.*

Calcaria Usta, *P.G.;* Calcaria, Calx Viva, Calx Usta, Oxydum Calcicum; Burned Lime; Quicklime; Chaux, Chaux vive, *Fr.;* Kalk, Gebrannter Kalk, *G.;* Calce, *It.;* Cal viva, *Sp.*

Lime, which is ranked among the alkaline earths, is a very important pharmaceutical agent, and forms the principal ingredient in several standard preparations. It is a very abundant natural production. It is never found free, but mostly combined with acids; as with carbonic acid in chalk, marble, calcareous spar, limestone, and shells; with sulphuric acid in the different kinds of gypsum; with phosphoric acid in the bones of animals; and with silica in a great variety of minerals.

Preparation. Lime is prepared by calcining, by a strong heat, some form of the native carbonate. The carbonic acid is thus expelled, and the lime remains. When the lime is intended for nice chemical operations, it should be obtained from pure white marble or oyster-shells. For the purpose of the arts it is procured from common limestone, by calcining it in kilns of peculiar construction. When obtained in this way it is generally impure, being of a grayish color, and containing alumina, silica, ferric oxide, and occasionally a little magnesia and manganese oxide.

The official lime of the United States and British Pharmacopœias is the lime of commerce, and therefore impure. It may be obtained purer by exposing pure white marble, broken into small fragments, in a covered crucible, to a full red heat for three hours, or till the residuum, when slaked and suspended in water, no longer effervesces on the addition of hydrochloric acid.

Properties. Lime is in "hard, white, or grayish-white masses, which, in contact with air, gradually attract moisture and carbon dioxide, and fall to a white powder; odorless; of a sharp, caustic taste. Soluble in about 750 parts of water at 15° C. (59° F.), and in about 1300 parts of boiling water; insoluble in alcohol. Soluble in diluted acetic, hydrochloric, or nitric acid. When sprinkled with about half its weight of water, lime becomes heated, and is gradually converted into a white powder (calcium hydrate or slaked lime). When this is mixed with about 3 or 4 parts of water, it forms a uniform smooth magma (milk of lime). Even at the highest degree of heat, lime remains unaltered and does not fuse. Its aqueous solution gives an intensely alkaline reaction with litmus paper. Its solution in diluted acetic acid gives, with ammonium oxalate test-solution, a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If 1 part of lime be slaked and then thoroughly mixed with 50 parts of water, and the greater portion of the milky liquid decanted, no hard, gritty particles should be found in the residue, nor should the addition of hydrochloric acid to this residue cause much effervescence (limit of *carbonate*), nor leave more than a slight, insoluble residue. If the decanted portion be dissolved in acetic acid and filtered, if necessary, a portion of the filtrate

should not be rendered turbid by potassium dichromate test-solution (absence of *barium*). In another portion of the filtrate, the addition of ammonia water should not produce more than a slight turbidity (limit of *aluminum*, etc.)." *U. S.*

Lime is calcium oxide, and consists of one atom of calcium 40, and one of oxygen 16. Its sp. gr. is 3·08, whilst the hydrate has the sp. gr. 2·078. (*Filhol.*) Its solubility in water is greatly increased by the addition of sugar or glycerin. (See *Syrupus Calcis.*) It is distinguished from the other alkaline earths by forming a very deliquescent salt (*calcium chloride*) by reaction with hydrochloric acid, and a sparingly soluble one with sulphuric acid. All acids, acidulous, ammoniacal, and metallic salts, borates, alkaline carbonates, and astringent vegetable infusions are incompatible with it.

Medical Properties. Lime acts externally as an escharotic, and was formerly applied to ill-conditioned *ulcers.* The *lime ointment* of Spender is made by incorporating four parts of washed slaked lime with one part of fresh lard and three parts of olive oil, previously warmed together. Mixed with potassa, lime forms *Potassa cum Calce.* As an internal remedy, it is always administered in solution. (See *Liquor Calcis;* also *Syrupus Calcis.*)

CALX CHLORATA. U. S. (Br.) Chlorinated Lime.

(CĂLX ȻHLŌ-RĀ'TĄ.)

"A compound resulting from the action of chlorine upon calcium hydrate, and containing not less than 35 per cent. of available chlorine. This preparation is often improperly called 'Chloride of Lime.' Chlorinated Lime should be kept in well-closed vessels, in a cool and dry place." *U. S.* "A product obtained by exposing slaked lime to the action of chlorine gas until absorption ceases." *Br.*

Calx Chlorinata, *Br.;* Chlorinated Lime; Hypochlorite of Lime or Calcium, Oxymuriate of Lime or Calcium, Bleaching Powder; Calcaria Chlorata, *P.G.;* Chloris Calcicus, Chloruretum Calcis, Calcis Chloridum, Calcii Hypochloris, *Lat.;* Chlorure de Chaux, Poudre de Tennant ou de Knox, *Fr.;* Chlorkalk, Bleichkalk, *G.;* Cloruro di Calce, *It.*

This compound, originally prepared as a bleaching agent in 1798 by Tennant, of Glasgow, is now enormously used both in the arts and in medicine.

The following is an outline of the process for making chlorinated lime on the large scale. A rectangular chamber is constructed, generally of silicious sandstone, the joints being secured by a cement of pitch, rosin, and dry gypsum. At one end it is furnished with an air-tight door, and on each side with a glass window, to enable the operator to inspect the process during its progress. The slaked or hydrated lime is sifted, and placed on wooden trays eight or ten feet long, two feet broad, and one inch deep. These are piled within the chamber to a height of five or six feet on cross-bars, by which they are kept about an inch asunder, in order to favor the circulation of the gas over the lime. The chlorine is generated in a leaden vessel nearly spherical, the lower portion of which is surrounded with an iron case, leaving an interstice two inches wide, intended to receive the steam for the purpose of producing the requisite heat. In the leaden vessel are five apertures. The first is in the centre of the top, and receives a tube which descends nearly to the bottom, and through which a vertical stirrer passes, intended to mix the materials, and furnished at the lower end with horizontal cross-bars of iron, or of wood sheathed with lead. The second is for the introduction of the common salt and manganese. The third admits a siphon-shaped funnel, through which the sulphuric acid is introduced. The fourth is connected with a pipe to lead off the chlorine. The fifth, which is near the bottom, receives a discharge-pipe passing through the iron case and intended for drawing off the residuum of the operation. The pipe leading off the chlorine terminates, under water, in a leaden chest or cylinder, where the gas is washed from hydrochloric acid. From this intermediate vessel the chlorine finally passes, by means of a pretty large leaden pipe, through the ceiling of the chamber containing the lime. The process of impregnation generally lasts four days, this time being necessary to form a good bleaching powder. If it be hastened, heat will be generated, which will favor the production of calcium chloride, with a proportional diminution of chlorinated lime.

The proportions of the materials generally adopted are 10 cwt. of common salt, mixed with from 10 to 14 cwt. of manganese dioxide: to which are added, in successive portions, from 12 to 14 cwt. of strong sulphuric acid, diluted before being used until its sp. gr. is about 1·65, which is accomplished by adding about one-third of its weight of water. In factories in which sulphuric acid is also made, the acid intended for this process is brought to the sp. gr. 1·65 only, whereby the expense of further concentration is saved.

Several electrolytic processes for the decomposition of sodium and potassium chlorides have

been brought to public attention within the last year or two, whereby caustic alkali on the one hand and chlorine on the other hand are produced. Of course the chlorine, if produced on a large scale, would be converted into bleaching powder for convenience of handling.

The importation of "bleaching powder" into the United States for the year 1895 was 100,456,774 lbs., valued at $1,644,835; in 1896, 104,053,877 lbs., valued at $1,579,358; for 1897, 99,274,138 lbs., valued at $1,375,560.

Properties. Chlorinated lime is "a white, or grayish-white, granular powder, exhaling the odor of hypochlorous acid, having a repulsive, saline taste, and becoming moist and gradually decomposing on exposure to air. In water or in alcohol it is only partially soluble. The aqueous solution first colors red litmus paper blue, and then bleaches it. If the salt be dissolved in diluted acetic acid, an abundance of chlorine gas is evolved, and only a trifling residue left undissolved. From this solution ammonium oxalate test-solution throws down a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.* When perfectly saturated with chlorine it dissolves almost entirely in water. When exposed to heat, it gives off oxygen and some chlorine, and is converted into calcium chloride. It is incompatible with the mineral acids, carbonic acids, and the alkaline carbonates. The acids evolve chlorine copiously, and the alkaline carbonates cause a precipitate of calcium carbonate. (See *Liquor Sodæ Chloratæ.*)*

Chlorinated lime is an oxidizing agent, the oxygen being derived from water, the hydrogen of which unites with the chlorine to form hydrochloric acid. It has a powerful action on organic matter, converting sugar, starch, cotton, linen, and similar substances into formic acid, which unites with the lime. (*W. Bastick.*) It also acts energetically on the volatile oils, including oil of turpentine, producing chloroform. (*Journ. de Pharm.*, Mars, 1855.)

Composition. The composition of bleaching powder is represented by the formula $CaOCl_2$, and it was formerly supposed to be a direct compound of lime with chlorine. This view, however, is not consistent with its reactions, for when distilled with dilute nitric acid it readily yields a distillate of aqueous hypochlorous acid, and when treated with water it is resolved into calcium chloride and hypochlorite, the latter of which may be separated in crystals by exposing the filtered solution to a freezing mixture, or by evaporating it in a vacuum over oil of vitriol and leaving the dense frozen mass to thaw upon a filter. A solution of calcium chloride mixed with hypochlorite then passes through, and feathery crystals remain on the filter, very unstable, but consisting, when recently prepared, of hydrated calcium hypochlorite, $Ca(OCl)_2 4H_2O$. These results seem at first sight to show that the bleaching powder is a mixture of calcium chloride and hypochlorite, formed according to the equation $2CaO + Cl_4 = CaCl_2 + Ca(ClO)_2$; but if this were its true constitution, the powder when digested with alcohol ought to yield a solution of calcium chloride containing half the chlorine of the original compound, which is not the case. Its constitution is, therefore, better represented by the formula $Ca\begin{cases} Cl \\ OCl \end{cases}$ suggested by Dr. Odling, this molecule being decomposed by water into chloride and hypochlorite in the manner just explained, and yielding with dilute nitric acid or sulphuric acid a distillate containing hydrochloric and hypochlorous acids, $CaCl(OCl) + 2HNO_3 = Ca(NO_3)_2 + HCl + HClO$. (Lunge and Schaeppi, *A. J. P.*, 1881; Lunge and Naef, *Ber. d. Chem. Ges.*, 1883.)† Lunge and Bachofen (*Zeitschr. f. Angew. Chem.*, 1893, 326) have determined the specific gravities of chlorinated lime solutions at 15° C. (See *Proc. A. P. A.*, 1894, 579.)

Impurities and Tests. Chlorinated lime may contain a great excess of lime, from imperfect impregnation with the gas. This defect will be shown by the large proportion insoluble in water. If it contain much calcium chloride, it will be quite moist, which is always a sign of inferior quality. When long and insecurely kept, it deteriorates from the gradual formation of calcium chloride and calcium carbonate. Several methods have been proposed

* Chlorinated lime is constantly becoming weaker on exposure, giving off chlorine or hypochlorous acid, probably through the influence of the atmospheric carbonic acid, which sets them free by combining with the lime. But it would seem that, even when closely confined, it sometimes at least gives off gaseous matter, as we have an account of a well-stopped bottle containing it having been broken by a violent explosion, without any peculiar exposure to heat. (See *A. J. P.*, 1861, p. 72.) M. Barreswil has found that the subjection of chlorinated lime to strong pressure greatly diminishes the tendency to decomposition. It is rendered in this way as hard as a stone, and may be kept long without undergoing change. (*Chem. News*, No. 58, p. 33.)

† According to Lunge's investigations, the best temperature for the absorption of chlorine by calcium hydrate is 40°–45° C.; from pure calcium hydrate a bleaching powder of 43 per cent. active chlorine can be produced, in which case allowance for 4 per cent. of moisture in the hydrate is made; strong mineral acids, when not used in excess, liberate only hypochlorous acid; dry carbon dioxide at normal temperature does not set free any chlorine, but at moderately elevated temperature drives off almost all the chlorine.

for determining its bleaching power, which depends solely on the proportion of loosely-combined chlorine. Walter proposed to add a solution of the bleaching powder to a standard solution of indigo sulphate, in order to ascertain its decolorizing power; but the objection to this test is that the indigo of commerce is very variable in its amount of coloring matter. The oxidation of an arsenous acid solution is largely used in practice. Lunge (*Ber. der Chem. Ges.*, 1886, p. 869) has also proposed to use hydrogen peroxide (H_2O_2) solution for the valuation of bleaching powder. The two solutions both liberate oxygen in exactly equal amount. This is measured in a nitrometer. According to Wittstein and Claude, the test of ferrous sulphate which was formerly official is not reliable. The U. S. P. volumetric method, which is based upon that of the British Pharmacopœia, is preferred. "If 0·35 (0·354) Gm. of Chlorinated Lime be thoroughly triturated with 50 C.c. of water and carefully transferred, together with the washings, into a flask, and then 0·8 Gm. of potassium iodide and 5 C.c. of diluted hydrochloric acid added, the reddish-brown liquid, mixed towards the end of the titration with a few drops of starch test-solution, should require, for complete decoloration, not less than 35 C.c. of sodium hyposulphite decinormal volumetric solution (each C.c. corresponding to 1 per cent. of available chlorine)." *U. S.*

The following is the test given in the British Pharmacopœia: "0·5 gramme of Chlorinated Lime, mixed with 1·5 grammes of *potassium iodide* dissolved in 200 cubic centimetres of *water*, produces, when acidulated with 6 cubic centimetres of *hydrochloric acid*, a reddish solution, which requires for the discharge of its color at least 46·8 cubic centimetres of the *volumetric solution of sodium thiosulphate*, corresponding to 33 per cent. of available chlorine." In this process iodine is separated by the chlorine in equivalent quantity, and imparts color to the liquid, which is removed by the sodium hyposulphite, by forming colorless compounds with the iodine; and the quantity required for this purpose measures the quantity of iodine, and consequently that of the chlorine, present in the chlorinated solution. (See *Sodii Hyposulphis.*)

Medical Properties and Uses. Chlorinated lime, externally applied, is a desiccant and disinfectant, and has been used with advantage in solution, as an application to ill-conditioned *ulcers*, *burns*, *chilblains*, and *cutaneous eruptions*, especially *itch;* as a gargle in *putrid sore throat;* and as a wash for the mouth to disinfect the breath, and for *ulcerated gums.* Internally, it is stimulant and alterative. It has been used to some extent internally, in *adynamic dysentery*, *typhus fever*, and various other *low diseases:* it may be considered as therapeutically equivalent to chlorine. The dose internally is from three to six grains (0·2–0·4 Gm.), dissolved in one or two fluidounces (30–60 C.c.) of water, filtered and sweetened with syrup. It should never be given in pills. As it occurs of variable quality, and must be used in solution more or less dilute, according to the particular purpose to which it is to be applied, it is impossible to give any very precise directions for its strength as an external remedy. From one to four drachms of the powder added to a pint of water, and the solution filtered, will form a liquid within the limits of strength ordinarily required. For the cure of *itch*, M. Derheims has recommended a much stronger solution—three ounces of the chloride to a pint of water, the solution being filtered, and applied several times a day as a lotion, or constantly by wet cloths. When applied to *ulcers*, their surface may be covered with lint dipped in the solution. When used as an ointment to be rubbed upon *scrofulous enlargements* of the lymphatic glands, this may be made of a drachm of the chloride to an ounce of lard. Chlorinated lime is less eligible for some purposes than the solution of chlorinated soda. (See *Liquor Sodæ Chloratæ.*)

Chlorine gas is a very active germicide, and, as chlorinated lime affords the best practical method of using it for ordinary disinfecting purposes, it seems proper to discuss the subject at this place. It has been proved by the concurrent results of numerous experimenters that chlorine, if present in the proportion of one part in one hundred in the atmosphere of a room, is able to destroy *disease-germs*, provided that the air and the objects are moist, and that the exposure continues for upwards of one hour. In the case of any infected room or confined space, as the hold of a ship, it seems to us, however, that the endeavor should be to have a larger proportion of the chlorine gas present for several hours, and, if it can be readily accomplished, steam should also be allowed to enter with the gas, so as to make sure that all parts shall be thoroughly moistened. The importance of this is shown by the experiments of Fischer and Proskauer, who found that dry anthrax spores maintained their integrity for one hour when exposed to the action of a dry chlorine atmosphere containing about forty-five per cent. of chlorine, whereas moistened spores were killed by an hour's exposure to a moist atmosphere containing four per cent. of chlorine. Dr. Sternberg found that six hours' exposure of vaccine lint upon ivory points to a moist atmosphere containing one part of chlorine in one hundred

was sufficient to destroy the infective power of the lint. Chlorine is not only germicidal, but it also has the power of decomposing sulphuretted hydrogen compounds, and thereby deodorizing. In all these employments of chlorine it must be remembered that it is not possible for human beings to breathe a chlorinated air, and that the apartment must be, therefore, empty, and also as hermetically sealed as possible to prevent the escape of the gas. The experiments of Dr. Duggan show that the hypochlorites as derived from chlorinated lime are very active germicides, one part to four hundred being capable of destroying moist germs in two minutes, and six parts to ten thousand killing the spores of the anthrax-bacilius in six hours. A half of one per cent. of the hypochlorites in solution is said to be sufficient to destroy spores almost instantly. Ordinary bleaching powder contains from twenty-five to forty per cent. of available chlorine; one part of the powder to one hundred of water is strong enough for ordinary purposes. The odor and taste of this solution are such that it can scarcely be considered a dangerous poison, and it has been affirmed, although with doubtful correctness, that such solution will not injure clothing, bedding, etc. The cost of bleaching powder for use in small quantities is so small that even a saturated solution may be prepared for use in the sick-room at a nominal cost. *For the destruction of disease-germs in urine, fecal discharges, sputa, etc., a saturated solution of bleaching powder appears to be in all respects the best disinfectant known.* As it is important to destroy the germs as soon as possible, this solution should be put into the receptacle to be used by the patient *before* the discharges are ejected into them. As the chlorinated solution attacks metals, the spit-cups, etc., should be of china or glass.

In consequence of its powers as a disinfectant, chlorinated lime is a very important compound in its application to medical police. It may be used with advantage for preserving bodies from exhaling an unpleasant odor, before interment, in the summer season. In juridical exhumations its use is indispensable, as it effectually removes the disgusting and insupportable fetor of the corpse. The mode in which it is applied, in these cases, is to envelop the body with a sheet completely wet with a solution made by adding about a pound of the powder to a bucketful of water. This solution may also be employed for disinfecting dissecting-rooms, privies, common sewers, docks, and other places with offensive effluvia.

Chlorinated lime acts exclusively by its chlorine, which, being loosely combined, is disengaged by the slightest affinities. It should, therefore, be carefully kept from contact with the air and organic substances, which cause rapid loss of chlorine, and the modern method of putting it up for ordinary use in hermetically sealed pasteboard boxes is a great convenience. Mr. R. C. Bicknell examined commercial chlorinated lime put up in these boxes for available chlorine; he found the top layers usually deficient in strength, but in the interior from 30 to 35 per cent. of chlorine. Some of the packages assaying 30 per cent. of chlorine were more than a year old. (*A. J. P.*, 1886, p. 593.) All acids, even carbonic, disengage it; and, as this acid is a product of animal and vegetable decomposition, noxious effluvia furnish the means, to a certain extent, of their own disinfection. But the stronger acids disengage the chlorine far more readily, and among these sulphuric acid is the most convenient. Accordingly, the powder may be dissolved in a very dilute solution of this acid; or a small quantity of the acid may be added to an aqueous solution ready formed, if a more copious evolution of chlorine be desired than that which takes place from the mere action of the carbonic acid of the atmosphere.

Chlorinated lime may be advantageously applied to the purpose of purifying offensive water, a property which makes it invaluable on long voyages. When used for this purpose, from one to two ounces of the chloride may be mixed with about sixty-five gallons of the water. The water must afterwards be exposed for some time to the air, and allowed to settle, before it is fit to drink.

CALX SULPHURATA. U. S., Br. Sulphurated Lime.

[Crude Calcium Sulphide.]

(CĂLX SŬL-PHŪ-RĀ'TĄ.)

"A mixture containing at least 60 per cent. of Calcium Monosulphide [$CaS = 71{\cdot}69$], together with unchanged Calcium Sulphate [$CaSO_4 = 135{\cdot}73$], and Carbon, in varying proportions." *U. S.* "A mixture containing not much less than 50 per cent. of calcium sulphide, CaS, with calcium sulphate and carbon. It may be prepared by reducing native calcium sulphate by means of carbon." *Br.*

Calcii Sulphidum; Sulphide of Calcium.

"Dried Calcium Sulphate, in fine powder, *seventy grammes* [or 2 oz. av., 205 grains]; Charcoal, in fine powder, *ten grammes* [or 154 grains]; Starch, *two grammes* [or 31 grains]. Mix them thoroughly, pack the mixture lightly into a crucible, cover this loosely, and heat it to

bright redness, until the contents have lost their black color. Allow the crucible to cool, reduce the product to powder, and at once transfer it to small, glass-stoppered vials." *U. S.*

The U. S. Pharmacopœia of 1890 abandoned the former process of preparing this substance, and adopted the British process (1885) with some modifications. The present British Pharmacopœia (1898) does not give a detailed process.

By decomposing a mixture of seven parts of calcium sulphate and one part of charcoal, heated in a crucible to a red heat, carbonic oxide is formed, which combines with the oxygen of calcium sulphate, and calcium sulphide is produced, $CaSO_4 + 4CO = CaS + 4CO_2$. A less convenient method is to pass hydrogen sulphide over red-hot lime, although if the lime be pure a better product is insured. This preparation, which was introduced into both Pharmacopœias, is of doubtful utility, particularly in the form in which it is produced. The amount of calcium sulphide present must vary considerably according to circumstances. The medicinal activity is alone measured by the quantity of sulphide in the finished preparation, calcium sulphate, the other constituent, being inert. It is to be regretted that a method of purification was not appended.

Properties. Sulphurated lime is "a pale gray powder, exhaling a faint odor of hydrogen sulphide, having a nauseous, alkaline taste, and gradually decomposed by exposure to air. Very slightly soluble in cold water, more readily in boiling water, which partially decomposes it; insoluble in alcohol. Sulphurated lime is decomposed by diluted acetic acid, and converted into calcium acetate and hydrogen sulphide gas which escapes, while a residue of calcium sulphate remains. The filtrate from this yields, with ammonium oxalate test-solution, a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.*

Test. "If 1 Gm. of Sulphurated Lime be gradually added to a boiling solution of 2·08 Gm. of cupric sulphate in 50 C.c. of water, the mixture digested on a water-bath for fifteen minutes, and filtered when cold, no color should be imparted to the filtrate by 1 drop of potassium ferrocyanide test-solution (presence of at least 60 per cent. of pure Calcium Monosulphide)." *U. S.* The British Pharmacopœia describes it as "A grayish-white powder with a smell of hydrogen sulphide. If 0·8 gramme be mixed with a cold solution of 1·4 grammes of *copper sulphate* in 50 cubic centimetres of *water*, and, after the addition of a little *hydrochloric acid*, the mixture be well stirred and heated to a temperature approaching that of ebullition until all action has ceased, and then filtered, the filtrate should give no red color with *solution of potassium ferrocyanide* (presence of a due proportion of sulphide)."

Calcium sulphydrate, or *calcium hydrosulphide*, $Ca(SH_2)$, is formed when hydrogen sulphide is passed into milk of lime as long as it is absorbed. It is in the form of a paste of a greenish-gray color, and exhales a strong odor of hydrogen sulphide.

Medical Properties. It is used as a *depilatory*, and is applied in a layer on the part which is to be deprived of hair. At the end of fifteen minutes it is removed with a wet sponge, which at the same time detaches the hairs. On account of this preparation giving out hydrogen sulphide, it should not be applied near the mouth or nose. An impure aqueous solution of calcium sulphide, necessarily containing calcium hyposulphite from the manner of its preparation, is used with great success, in Belgium, in *itch*, the cure of which it effects in a few hours. It is made by boiling together one part of sublimed sulphur, two of lime, and ten of water. The liquid is allowed to cool, and the clear part poured off and kept in well-stopped bottles. For an explanation of the reaction which takes place, see *Sulphur Præcipitatum*. The patient, after having been well washed with soap and tepid water in a bath, is rubbed over with the liquid, which is allowed to dry on the skin for a quarter of an hour. A second bath is then taken, which completes the cure. The preparation, when it dries, leaves on the skin a thin layer of the sulphur compound, which destroys the itch insect and its eggs.

Calcium sulphide has been strongly recommended by Ringer, Duhring, and other authorities as a remedy for *furuncular eruptions*, and it has also been used successfully in *acne*. It is given in doses of from one-tenth to one-half grain (0·00648–0·0324 Gm.).

CAMBOGIA. U. S., Br. Gamboge.

(CĂM-BŌ'JĬ-Ą.)

"A gum-resin obtained from Garcinia Hanburii, Hooker filius (nat. ord. Guttiferæ)." *U. S.*
"A gum-resin obtained from Garcinia Hanburii, Hook. f." *Br.*

Gambogia, *Pharm.* 1870; Gomme gutte, *Fr.*; Gummigutt, *G.*; Gumma-gotta, *It.*; Gutta gamba, *Sp.*

Several plants belonging to the natural family of Guttiferæ, growing in the equatorial regions, yield on incision a yellow opaque juice, which hardens on exposure and bears a close

resemblance to gamboge; but it is only from a particular tree, growing in Siam, that the official gum-resin is procured.* Formerly the United States and all the British Pharmacopœias ascribed it to *Stalagmitis cambogioides.* Both the genus and the species were established by Murray, of Göttingen, in 1788, from dried specimens belonging to König, procured in Ceylon; and, from information derived from the same source, it was conjectured by Murray that the tree yielded not only the gamboge of Ceylon, but also that collected in Siam. On this authority the British Colleges made the references alluded to. But it was ascertained by Dr. Graham, of Edinburgh, that there is no such plant as *Stalagmitis cambogioides;* the description of Murray having been drawn up from accidentally conjoined specimens of two trees belonging to different genera, one being the *Xanthochymus ovalifolius* of Roxburgh, and the other the *Hebradendron cambogioides* of Graham. By several botanists the gum-resin has been ascribed to *Garcinia cambogia*, also a tree of Ceylon belonging to the Guttiferæ and yielding a yellowish concrete juice; but a specimen of this juice, sent to Edinburgh, was found by Dr. Christison to differ from gamboge both in composition and appearance, being of a pale lemon-yellow color. Thus it appears that neither of these references is correct; and, besides, the fact seems to have been overlooked that commercial gamboge is never obtained from Ceylon, but exclusively from Siam and Cochin-China. A gum-resin from Ceylon having been found similar in composition to the gamboge of commerce, and the tree which produced it having been referred by Dr. Graham to a new genus and named by him *Hebradendron cambogioides*, the Edinburgh College, in the last edition of its Pharmacopœia, was induced to adopt this Ceylon gamboge as official, and to recognize the name proposed by Dr. Graham for the tree producing it. But, as this variety is never found in western commerce, and exists only in cabinets, or in the bazaars of India, it scarcely merited a place in an official catalogue; moreover, the genus Hebradendron is not acknowledged by botanists. The *H. cambogioides* is the *Garcinia pictoria* of Roxburgh (*Flor. Ind.*, ii. 627), which Sir Joseph Hooker considers to be a variety of the *G. morella* (Desrous.); though Beddome keeps it distinct on account of its having the fertile flower bearing "the staminodes in bundles, and the stigma very small and 4-lobed." Several years since, Dr. Christison received from Singapore specimens of the gamboge plant cultivated in that island, and derived from Siam, which proved to be a Garcinia, differing from the *G. elliptica* of Wallich chiefly in having its male flower upon pedicels. Subsequently Mr. Hanbury obtained from the same source numerous specimens of the same plant, and was enabled to confirm the statement of Dr. Christison; but he also found that the plant approached very near to the *Garcinia morella* of Desrousseaux, from which it could be distinguished only by its pedicellate flowers. These specimens were afterwards submitted to the inspection of Mr. Thwaites in Ceylon, who is perfectly familiar with the Garcinias of that island, and were pronounced by him to belong to a variety of *G. morella*, scarcely differing from the Ceylon plant, except in having pedicelled instead of sessile flowers; for these two varieties the names of *G. morella*, var. *sessile*, and *G. morella*, var. *pedicellata*, were proposed. Sir Joseph Hooker, however, determined (*Journ. Linn. Soc.*, xiv. 485) that the var. *pedicellata* is a distinct species, differing from *G. morella* in having not only its flowers pedicellate, but also its leaves more ovate and much larger, and its fruit larger: he very properly gave it the specific name of Hanburii to commemorate the contributions of the late Mr. Hanbury to pharmaceutical science, and his connection with the history of the present plant. According to the researches of Beckett, *G. Hanburii* is confined to the islands and sea-coast of the Gulf of Siam, where it is known as "*Ton Rong*," and where it grows to the height of fifty feet, with a diameter of twelve inches.

Gamboge is said to be procured in Siam by breaking off the leaves and shoots of the tree; the juice, which is contained in ducts or latex vessels in the bark, issues in drops, and, being received in suitable vessels, gradually thickens, and at length becomes solid. Dr. Jamie, of Singapore, states that incising the trunk and larger branches is often practised. The juice is frequently received into the hollow joints of the bamboo, and the water expelled by mild continuous heat. In this way the so-called pipe gamboge is formed, the contraction during drying causing the cylinders to be hollow. According to Beckett, Siam gamboge is obtained only from trees of not less than ten years of age and during the rainy months, from June to October, by cutting long, spiral grooves into the bark and collecting in hollow bamboos the sap which trickles down in a viscous stream. (*Kew Bulletin*, 1895.)

The name *gummi gutta*, by which gamboge is generally known on the continent of Europe,

* According to observations of Messrs. Baildon and Jamie, gamboge is obtained exclusively from the province of Cambodia, the plant not being found in any other part of Siam nor in Cochin-China. (*Journ. de Ph.*, Juillet, 1874.)

probably originated from the circumstance that the juice escapes from the plant by drops. The official title was undoubtedly derived from the province of Cambodia, in which the gum-resin is collected. Gamboge was first brought to Europe by the Dutch, about the middle of the seventeenth century. We import it from Canton and Calcutta, whither it is carried by the native or resident merchants. There is no difference in the appearance or character of the drug as brought from these two ports,—an evidence that it is originally derived from the same place.

Varieties. The best gamboge is in cylindrical rolls, from one to three inches in diameter, sometimes hollow in the centre, sometimes flattened, often folded double, or agglutinated in masses so that the original form is not always easily distinguishable. The pieces sometimes appear as if rolled, but are in general striated longitudinally from the impression made by the inner surface of the bamboo. They are externally of a dull orange color, which is occasionally displaced by greenish stains, or concealed by the bright yellow powder of the drug, slightly adhering to the surface. In this form the drug is sometimes called *pipe gamboge.* Another variety is imported under the name of *cake* or *lump gamboge.* It is in irregular masses of two or three pounds or more, often mixed with sticks and other impurities, containing many air-cells, less dense, less uniform in texture, and less brittle than the former variety, and breaking with a dull and splintery instead of a shining and conchoidal fracture. The worst specimens of this variety, as well as of the cylindrical, are sometimes called by the druggists *coarse gamboge.* They differ, however, from the preceding only in containing a greater amount of impurities. Indeed, it would appear from the experiments of Christison that all the commercial varieties of this drug have a common origin, and that cake or lump gamboge differs from the cylindrical only in the circumstance that the latter is the pure concrete juice, while to the former farinaceous matter and other impurities have been added for the purpose of adulteration. The inferior kinds of gamboge may be known by their greater hardness and coarser fracture; by the brownish or grayish color of their broken surface, which is often marked with black spots; by their obvious impurities; and by the green color which their decoction, after having been cooled, gives with tincture of iodine (starch). When pure, the gum-resin is completely dissolved by the successive action of ether and water,* so that the amount of residue left by any specimen treated in the manner just spoken of indicates approximately the measure of the adulteration.

Properties. The official description is as follows. "In cylindrical pieces, sometimes hollow in the centre, 2 to 5 Cm. in diameter, longitudinally striate on the surface; fracture flattish-conchoidal, of a waxy lustre, orange-red; in powder bright yellow; inodorous; taste very acrid; the powder sternutatory. Gamboge is partly soluble in alcohol and in ether. When triturated with water, it yields a yellow emulsion, and forms with solution of potassium or sodium hydrate an orange-red solution, from which, on the addition of hydrochloric acid, a yellow resin is precipitated. Boiled with water, Gamboge yields a liquid which, after cooling, does not become green with iodine test-solution (absence of *starch*)." *U. S.* From the brilliancy of its color, gamboge is highly esteemed as a pigment. It has no smell, and little taste, but, after remaining a short time in the mouth, produces an acrid sensation in the fauces. Its sp. gr. is 1·221, and its chemical formula is given as $C_{20}H_{24}O_4$. "When *solution of iodine* is added to a cooled aqueous decoction, the color should not become distinctly green (absence of more than a trace of starch). When incinerated it should not yield more than 3 per cent. of ash." *Br.* It is a gum-resin, without volatile oil. Christison has shown that the proportion of gum and resin varies in different specimens even of the purest drug. In one experiment, out of 100·8 parts he obtained 74·2 of resin, 21·8 of gum, and 4·8 of water. The gum is quite soluble in water, and of the variety denominated arabin. Flückiger, however, says that the gum is not identical with gum arabic, as its solution does not redden litmus, and is not precipitated by neutral lead acetate, nor by ferric chloride, nor by sodium silicate or biborate. By fusing purified gamboge resin with potash, Hlasiwetz and Barth (*Ann. Ch. und Pharm.*, 138, 61) obtained acetic and other acids of the same series, together with *phloroglucin*, $C_6H_3(OH)_3$,

* *Ceylon gamboge*, derived from the *Hebradendron cambogioides* of Graham (*Cambogia gutta*, Linn., *Garcinia morella*, De Cand., *G. pictoria*, Roxb.), is procured by incisions, or by cutting away a portion of the bark, and scraping off the juice which exudes. The specimens sent to Dr. Christison were in flattish or round masses, eight or nine inches in diameter, apparently composed of aggregated irregular tears, with cavities which are lined with a grayish and brownish powdery incrustation. It resembled coarse gamboge, and was identical in composition. In Ceylon it is used as a pigment and purgative. (Christison.) *New Caledonian Gamboge*, derived from *Garcinia Collina* (Vieil), is described by Heckel and Schlagdenhauffen as very similar in its appearance and reactions to ordinary gamboge; its color is, however, deep orange. A white crystalline compound, which when heated beyond 235° C. produced pyrocatechin, was found in it, and marked the point of difference between it and other varieties of gamboge. (*Rép. de Pharm.*, 1893, 193.)

pyrotartaric acid, $C_5H_8O_4$, and *isovitinic acid*, $C_6H_3CH_3(COOH)_2$. Sassarini found gamboge to contain the following constituents. 1. Gum analogous to arabin. 2. Volatile oil, consisting of terpene and a camphor. 3. Isovitinic and acetic acids. 4. A phenol ester. 5. Resin. 6. Methyl alcohol and some higher homologues. 7. A liquid having a fruity odor resembling aldehyde or acetone. He believes phloroglucin found by others to be a decomposition product. (*Ann. di Chim. Farm.*, 1897.) Gamboge is readily and entirely diffusible in water, forming a yellow opaque emulsion, from which the resin is very slowly deposited. It yields its resinous ingredient to alcohol, forming a golden-yellow tincture, which is rendered opaque and bright yellow by the addition of water. Its solution in ammoniated alcohol is not disturbed by water. Ether dissolves about four-fifths of it, taking up only the resin. It is wholly taken up by alkaline solutions, from which it is partially precipitated by the acids. The strong acids dissolve it; the solution when diluted deposits a yellow sediment. The color, acrimony, and medicinal power of gamboge are thought to reside in the resin. Prof. Hirschsohn gives a method for detecting gamboge in mixtures in *Pharm. Zeit. f. Russl.*, xxiv. (*A. J. P.*, 1885.)

Medical Properties and Uses. Gamboge is a powerful, drastic, hydragogue cathartic, so very apt to produce nausea and vomiting and much griping when given in the full dose that it is almost never employed except in combination with other cathartics. In large quantities it is capable of causing fatal effects, and death has resulted from a drachm. The full dose is from two to six grains (0·13–0·4 Gm.), which in cases of *tænia* has been raised to ten or fifteen grains. It may be given in pill or emulsion, or dissolved in an alkaline solution. In the dose of five grains the resin is said to produce copious watery stools, with little or no uneasiness. If this be the case, it is probable that, as it exists in the gum-resin, its purgative property is somewhat modified by the other ingredients.

CAMPHORA. U. S., Br. Camphor.

$C_{10}H_{16}O$; 151·66. (CĂM'PHŌ-RĄ.) $C_{10}H_{16}O$; 152.

"A stearopten (having the nature of a ketone) obtained from Cinnamomum Camphora (Linné), Nees et Ebermaier (nat. ord. Laurineæ), and purified by sublimation. Camphor should be kept in well-closed vessels, in a cool place." *U. S.* "A white crystalline substance obtained from Cinnamomum Camphora, Nees and Eberm., purified by sublimation." *Br.*

Camphre, *Fr.;* Kampher, Kampfer, *G.;* Canfora, *It.;* Alcanfor, *Sp.*

The name of camphor has been applied to various concrete, white, odorous, volatile products, found in different aromatic plants, and resulting probably from chemical change in their volatile oil. But commercial camphor is derived exclusively from two plants, the *Camphora officinarum* of Nees or *Laurus camphora* of Linnæus, and the *Dryobalanops camphora;* the former of which yields our official camphor, the latter a product much valued in the East, but unknown in the commerce of this country and of Europe.

Gen. Ch. For characters of genus Cinnamon, see *Cinnamomum.* The genus Camphora as separated by Nees departs from the characters there given, in the segments of the perianth being completely deciduous, and falling off completely, leaving the berry resting upon the somewhat enlarged cup-shaped or disk-shaped, entire, or slightly serrate base or tube.

Camphora officinarum. Nees, *Laurin.* 88; Carson, *Illust. of Med. Bot.* ii. 29, pl. xxiv.—*Laurus camphora.* Willd. *Sp. Plant.* ii. 478.—*Cinnamomum camphora*, *B. & T.* 222. The camphor-tree is an evergreen which sometimes attains great size,* having the aspect of the linden, with a trunk straight below, but divided above into many branches, which are covered with a smooth, greenish bark. Its leaves, which stand alternately upon long footstalks, are ovate-lanceolate, entire, smooth and shining, ribbed, of a bright yellowish-green color on their upper surface, paler on the under, and two or three inches in length. The flowers are small, white, pedicelled, and collected in clusters, which are supported by long axillary peduncles. The fruit is a red berry, resembling that of the cinnamon. The camphor-tree is a native of China, Japan, and adjacent portions of eastern Asia, but grows very well in India, and is capable of cultivation in California, Florida, and other portions of the United States not subject to severe frosts. (See circular of the U. S. Department of Agriculture, prepared by Lyster H. Dewey.) Its growth is, however, so extremely slow that it is hardly probable that American capitalists will undertake its cultivation.†

* A tree seen by Kämpfer, in Japan, in 1691, with a trunk 36 feet in circumference, was in the year 1826 described by Siebold as having a circumference of 50 feet.

† Within a few years the price of camphor has enormously risen. This has been stated to be due to the fact that, whilst in the government forests of southern Japan a certain amount of discretion is employed in the cutting of

The leaves have when bruised the odor of camphor, which is diffused through all parts of the plant, and is obtained from the root, trunk, and branches by sublimation. The process is not precisely the same in all places. The following is said to be the one pursued in Japan.* The parts mentioned, particularly the roots and smaller branches, are cut into chips, which are placed with a little water in large iron vessels, surmounted by earthen capitals furnished with a lining of rice-straw. A moderate heat is then applied, and the camphor, volatilized by the steam, rises into the capital, where it is condensed upon the straw. In China the comminuted plant is said to be first boiled with water until the camphor adheres to the stick used in stirring, when the strained liquor is allowed to cool, and the camphor which concretes, being alternated with layers of earth, is submitted to sublimation. In the island of Formosa, where the camphor-tree abounds, the chips are heated in a rough still. This is usually composed of a furnace surmounted with a trough or similar rude vessel, which is protected by clay. In this reservoir the chips are placed, with water upon them, and a perforated board luted upon the top; on this are set earthen pots. A fire having been lighted, steam rises through the chips and carries the camphor with it to deposit it in the pots. The crude camphor is taken to the towns in baskets and then put into large vats, with holes in the bottom, through which an oil escapes called *camphor-oil*, much used by the Chinese for medical purposes. It is said that of recent years hydraulic pressure is largely substituted for drainage, and that the camphor, thus drained, is packed in bags and exported. (*P. J. Tr.*, Dec. 1863, p. 280.)

Commercial History. Camphor, in the *crude* state, is brought to this country chiefly from Canton. It comes also from Batavia, Singapore, Calcutta, and frequently from London. All of it is probably derived originally from China and Japan. Two commercial varieties are found in the market. The cheapest and most abundant is the *Chinese camphor*, most of which is produced in the island of Formosa and thence taken to Canton. It comes in chests lined with lead, each containing about 130 pounds. It is in small grains or granular masses, of a dirty-white color, and frequently mixed with impurities. It has occurred in commerce adulterated with ammonium chloride. The other variety is variously called *Japan*, *Dutch*, or *tub* camphor, the first name being derived from the place of its origin, the second from the people through whom it was introduced into commerce, and the third from the recipient in which it is often contained. It has usually come from Batavia, to which port it was taken from Japan. Like the former variety, it is in grains or granular masses; but the grains are larger and of a pinkish color, and there are fewer impurities, so that it yields a larger product when refined. Within the last few years camphor has been increasingly produced on the Chinese mainland, the tree being, it is said, extensively cultivated in Kwang-Si. In Fukien the camphor is stated to be obtained to a trifling extent from wild trees.

Crude camphor, as brought from the East, is never found in the shop of the apothecary. It must be refined before it can be used for medicinal purposes. The process for refining camphor was first practised in Europe by the Venetians, who probably derived it from the Chinese. It was afterwards transferred to the Dutch, who long enjoyed a monopoly of this business; and it is only within a few years that the process has been generally known. It is now practised largely in this country, and the camphor refined in our domestic establishments is equal to any formerly imported. Crude camphor is mixed with about one-fiftieth of quicklime, and exposed, in an iron vessel placed in a sand-bath, to a gradually increasing heat, by which it is melted, and ultimately converted into vapor, which condenses in a suitable recipient.†

plants, the private forests, which yield four-fifths of the national product, are becoming exhausted by wanton destruction. In Formosa camphor distilling has been carried on in the most recklessly extravagant and wasteful manner. It would seem, however, that the increase of price is not due so much to decrease of supply as to increase of demand, through the growing use of camphor in the arts (especially in the manufacture of celluloid), as is shown by the following official report of the total Japanese export during twelve years. 1880, 20,220 piculs; 1881, 21,344 piculs; 1882, 31,610 piculs; 1883, 35,660 piculs; 1884, 29,900 piculs; 1885, 22,207 piculs; 1886, 34,952 piculs; 1887, 48,164 piculs; 1888, 28,394 piculs; 1889, 41,115 piculs; 1890, 37,161 piculs; 1891, 38,504 piculs.

* For detailed description, see *P. J. Tr.*, xv. 167; also *Proc. A. P. A.*, 1884, 132.

† We are informed that the process is conducted in the following manner in some of the laboratories of Philadelphia. The vessels in which the camphor is put are of cast iron, circular, from 12 to 15 inches or more in diameter, and 4 inches deep, with perpendicular sides, and a ledge at top, on which the cover rests. This consists of sheet iron, with a hole through the centre about an inch in diameter, over which a small hollow cone of sheet iron is placed loosely. The crude camphor mixed with the lime, the object of which is said to be to combine with the moisture present, which interferes with the due solidification of the camphor vapor, is placed in the iron vessels described, of which from 20 to 50 are arranged in a long sand-bath. Heat is then applied until the camphor melts, after which it is kept as nearly uniform as possible, so that the vaporation may take place regularly, without violent ebullition. The vapor condenses on the lower surface of the lid; and care is taken, by the occasional removal of the iron cone, and clearing of the opening by means of a knife, to allow the escape of any accidental excess of the vapor.

Refined in this manner, it is usually in the form of large circular cakes, one or two inches thick, slightly convex on one side and concave on the other, and perforated in the centre. Camphor can also be made artificially by the oxidation of *camphene*, $C_{10}H_{16}$, with chromic acid mixture. Camphene is obtained from either pinenehydrochloride (so-called artificial camphor) or from bornyl chloride by treatment with alcoholic potash, and is a solid crystalline mass, fusing at 49° C. The importations of camphor for the past few years have been: for 1895, 1,500,739 lbs., valued at $284,968; for 1896, 945,629 lbs., valued at $328,457; for 1897, 1,469,601 lbs., valued at $332,748.

Properties. "White, translucent masses, of a tough consistence and a crystalline structure, readily pulverizable in the presence of a little alcohol, ether, or chloroform; having a penetrating, characteristic odor, and a pungently aromatic taste. Specific gravity, 0·995 at 15° C. (59° F.). Very sparingly soluble in water, but readily soluble in alcohol, ether, chloroform, carbon disulphide, benzin, and in fixed and volatile oils. When Camphor is triturated, in about molecular proportions, with menthol, thymol, phenol, or chloral hydrate, liquefaction ensues. It melts at 175° C. (347° F.), boils at 204° C. (399·2° F.), and is inflammable, burning with a luminous, smoky flame. On exposure to the air it evaporates more or less rapidly at ordinary temperatures, and, when moderately heated, it sublimes without leaving a residue." *U. S.* Camphor has a peculiar, strong, penetrating, fragrant odor, and a bitter, pungent taste, with a slight sense of coolness. It is beautifully white and pellucid, somewhat unctuous to the touch, brittle, and yet possessed of a tenacity which renders its reduction to a fine powder very difficult, unless its cohesion be overcome by the addition of a minute proportion of alcohol, ether, chloroform, glycerin, essential or fatty oil, or other volatile liquid for which it has an affinity. It may be obtained in powder by pulverizing with an equal weight of sugar, by precipitating the tincture with water, or by grating and afterwards sifting it,* or, better yet, by sublimation. The fracture of camphor is shining, and its texture crystalline. Its sp. gr. varies from 0·9857 to 0·996. When thrown in small fragments upon water, it assumes singular circulatory movements, which cease upon the addition of a drop of oil; and this property has been applied to the detection of grease in liquids, a very small proportion of which is sufficient to prevent the movements. Its volatility is so great that, even at ordinary temperatures, it is wholly dissipated if left exposed to the air. When it is confined in bottles, the vapor condenses on the inner surface, and, in large bottles partially filled, sometimes forms, after long standing, large and beautiful crystals. It melts at 175° C. (347° F.), boils at 204° C. (399·2° F.), and, in close vessels, sublimes unchanged. When allowed to concrete slowly from the state of vapor, it assumes the form of hexagonal plates. It is not altered by air and light. It readily takes fire, burning with a brilliant flame, with much smoke, and without residue. Water triturated with camphor dissolves, according to Berzelius, not more than 1000th part; which, however, is sufficient to impart a decided odor and taste to the solvent. By the intervention of sugar or magnesia a much larger proportion is dissolved. (See *Aqua Camphoræ.*) Carbonic acid increases the solvent power of water, as also does the spirit of nitrous ether. Ordinary alcohol will take up 75 per cent. of its weight of camphor, which is precipitated upon the addition of water. Berzelius states that 100 parts of alcohol, of the sp. gr. 0·806, dissolve 120 parts at 10° C. (50° F.). It is soluble without change in ether, the volatile and fixed oils, strong acetic acid, and diluted mineral acids, and is extremely soluble in chloroform. "It is soluble in about 700 parts of *water*, in about 1 part of *alcohol* (90 per cent.), in one-quarter part of *chloroform*, and in 4 parts of *olive oil;* very soluble in *ether*." *Br.* Nitric acid on prolonged boiling with camphor oxidizes it into *camphoric acid*, $C_{10}H_{16}O_4$,† and *cam-*

* But the powder thus formed is apt to aggregate on keeping. To obviate this it is recommended to rub it up with a minute proportion of magnesium carbonate, from 10 to 20 grains to the ounce; or, as suggested by the late Mr. Henry F. Fish, of New York, to pour an alcoholic solution of camphor into water in which magnesium carbonate is suspended, the proportion employed being 16 ounces of camphor to a drachm of the carbonate suspended in a gallon of water. The powder is allowed to settle on a filter. (*A. J. P.*, Nov. 1870, 506.) Another method of accomplishing the same object, proposed by Mr. John C. Lowd, is to sublime camphor from a retort into a large chamber, and collect the powder. (*Ibid.*, March, 1872, 112.)

A still better plan is to dissolve camphor in one and a half parts of alcohol, and pour this solution with stirring into four parts of water. Collect the precipitate, wash with water, and dry. By noting the quantity of camphor used, the amount left dissolved in the diluted alcohol can be calculated, and this solution used in making tincture.

† *Camphoric acid* occurs in small, white, acicular or scaly crystals, free from odor, of a feebly acid taste, sparingly soluble in cold, freely in hot, water, also in alcohol, ether, and fatty oils, and having a melting point of about 176° F. It is made by boiling camphor or campholic acid with concentrated nitric acid, and Maissen states that the best results are obtained by using a mixture of camphor and borneol, produced by the action of sodium on camphor.

Camphoric acid appears to be a valuable remedy, of distinct power in checking the *colliquative sweats* of phthisis and perhaps of other diseases, and having a special relation with the mucous membranes. It has been highly com-

phoronic acid, $C_9H_{12}O_5$. Schwanert's *camphresinic acid*, $C_{10}H_{14}O_{12}$, is, according to Kachler, a mixture of these two. Sulphuric acid in the proportion of ten parts to one gives, when heated with camphor, an oil isomeric with camphor, boiling at 200° C. (392° F.), and yielding a solid camphor when distilled repeatedly over solid caustic potash. Sulphuric acid in the proportion of four to one gives with camphor, according to Chautard, a volatile product which he calls *camphrene*, and to which Schwanert gives the formula $C_9H_{14}O$. Kachler (*Ann. Ch. und Pharm.*, 164, p. 90) considers, however, that camphrene is only *phorone* (a condensation product of acetone) with slight impurities. Alcoholic potash solution heated with camphor gives a derivative called *campholic acid*, $C_{10}H_{18}O_2$, a white solid, fusing at 95° C. (203° F.), and boiling at 250° C. (482° F.). Resins unite with it, forming a soft tenacious mass, in which the odor of the camphor is sometimes almost extinguished, and frequently diminished; and a similar softening effect results when it is triturated with the concrete oils.* Exposed to a strong heat, in close vessels, camphor is resolved into carbonic acid gas and hydrocarbons, among which cymol is especially to be recognized.

Camphor, $C_{10}H_{16}O$, and borneol, $C_{10}H_{18}O$,† are classified together as belonging to the group

mended both internally and locally in *bronchitis* and *phthisis*. As a local application, the 1 per cent. solution is said to act most happily in ordinary *sore throat* and in *laryngitis*; but in the clinic of Professor Mosler, inhalations of camphoric acid solution failed to achieve good in *bronchitis* and in *pulmonary tuberculosis*. In *chronic cystitis* the bladder may be washed out twice a day with a half of 1 per cent. solution, an ounce or so of the solution being left in the bladder, and the strength of the solution increased as necessary. In *pyelitis*, as well as in *cystitis*, the drug should be given by the mouth. Warman claims great value for the remedy in *chronic gonorrhœa*. Fürbringer found it to be useful as an intestinal disinfectant, and it would seem to be a valuable remedy in the treatment of *diarrhœa*. It appears to be rapidly absorbed and as rapidly eliminated, as it may be found in the urine from two to five hours after its ingestion. (*Bohland.*) When used locally it can generally be given internally with advantage at the same time. Dose, 10 to 30 grains (0·650 to 1·95 Gm.), three times a day, in capsule. In the case of night-sweats the large dose may be given at bedtime, or, when the sweats come on towards morning, in the middle of the night.

Oxycamphor, $C_8H_{14}\begin{cases}\text{CHOH}\\ |\\ \text{CO}\end{cases}$, is a white crystalline powder, slightly soluble in cold water (2 per cent.), but freely soluble in alcohol, ether, chloroform, and oils. It has been used as a remedy in dyspnœa in doses of from eight to sixteen grains (0·5 to 1 Gm.). (*Deutsch Med. Woch.*, 1897, No. 27.)

* As this property of camphor may have a bearing, injuriously or otherwise, on pharmaceutical processes, it is desirable that the operator, as well as the prescriber, should be aware of the degree of effect produced by different resinous substances which may be mixed with it. M. Planche has found that mixtures formed by triturating powdered camphor with powdered *dragon's blood*, *guaiac*, *asafetida*, and *galbanum* assume, and preserve indefinitely, the pilular consistence; with *benzoin*, *tolu*, *ammoniac*, and *mastic*, though at first of a pilular consistence, afterwards become soft by exposure to the air; with *sagapenum* and *animé*, assume a permanently semi-liquid form; with *olibanum*, *opopanax*, *gamboge*, *euphorbium*, *bdellium*, *myrrh*, and *amber*, remain pulverulent, though somewhat grumous; and with *tacamahac*, *resin of jalap*, *sandarac*, and *resinoid matter of cinchona*, preserve the form of powder indefinitely. The same experimenter observed that camphor loses its odor entirely when mixed with *asafetida*, *galbanum*, *sagapenum*, *animé*, and *tolu*; retains a feeble odor with *dragon's blood*, *olibanum*, *mastic*, *benzoin*, *opopanax*, *tacamahac*, *guaiac*, and *ammoniac*; while with the other resinous substances above mentioned, it either has its odor increased, or retains it without material change. (*Journ. de Pharm.*, xxiv. 226.)

In mixing camphor with other substances in the form of powder, it is best to first pulverize the camphor with the aid of a little alcohol, then to pulverize the other substances together, and lastly to mix the two powders gently; much rubbing with the pestle having the effect of consolidating the granules of the camphor. (*Procter.*)

† *Sumatra Camphor. Borneo Camphor. Dryobalanops Camphor. Baros Camphor. Borneol.* This camphor is produced in the islands of Sumatra and Borneo, by *Dryobalanops camphora*, or *D. aromatica*. This tree is very large, often exceeding one hundred feet in height, with a trunk six or seven feet in diameter, and ranks among the tallest and largest trees in India.* It is found in Sumatra and Borneo, and is abundant on the northwest coast of the former island. The camphor exists in concrete masses, which occupy longitudinal cavities or fissures in the heart of the tree, from a foot to a foot and a half long, at certain distances apart. The younger trees are generally less productive than the old. The only method of ascertaining whether a tree contains camphor is by incision. A party proceed through the forest, wounding the trees, till they find one which will answer their purpose; and hundreds may be examined before this object is attained. When discovered, the tree is felled and cut into logs, which are then split, and the camphor removed by means of sharp-pointed instruments. It is stated that the masses are sometimes as thick as a man's arm; and that the product of a middling-sized tree is nearly eleven pounds; of a large one, double that quantity. The trees which have been wounded and left standing often produce camphor seven or eight years afterwards. Mrs. Ida Pfeiffer states, in her *Second Journey round the World* (Am. ed., p. 183), that the camphor is also found in a concrete state under the bark, and is swept down with long brooms. The whole tree is pervaded more or less by the camphor or the oil. The wood retains a fragrant smell, and, being on this account less liable to the attacks of insects, is highly esteemed for carpenter-work.

Borneo camphor resembles in appearance ordinary camphor, but has, according to Christison, a specific gravity of 1·009, and sinks in water. Its odor is also distinctly different from that of camphor. It usually pulverizes without the addition of alcohol, is less volatile than ordinary camphor, and does not crystallize in the interior of the bottles in which it is kept. It fuses at 206° C. and boils at 212° C.; is dextrogyrate; has a formula of $C_{10}H_{17}(OH)$;

* For a particular description of this tree, see a paper by Dr. W. H. De Vriese, of Leyden, in the *A. J. P.* (xxiv. 329), taken from Hooker's Journal of Botany. In this paper it is stated on the authority of Dr. Junghuhn, who witnessed the process of collection, that the camphor is deposited in very small quantities in minute fissures between the fibres, from which it is scraped off by small splinters of wood, or by the nail; and the thickest and oldest trees seldom yield more than two ounces. This account as to the productiveness of the tree differs greatly from that of Colebrook, as stated in the note above.

called in general *camphors*, which occur with the *terpenes* or essential oils, $C_{10}H_{16}$, and are to be considered as oxidation products of these latter.

Borneol is an alcohol, yielding compound ethers when heated to about 200° C. (392° F.) with organic acids. It is a secondary alcohol, and therefore contains the group CH.OH linked to a more complex group. Secondary alcohols by oxidation yield *ketones*, by the change of the CH.OH group to CO. Common camphor bears this relation to borneol, and is therefore considered as a ketone, although not capable of being formed directly from borneol. The action of metallic sodium, however, upon common camphor, $C_{10}H_{16}O$, yields borneol, $C_{10}H_{18}O$.

Genuine camphor is said to be sometimes adulterated with the artificial, which may be detected by the action of ammonia upon its alcoholic solution, causing a flocculent precipitate, which does not redissolve, and the quantity of which is proportionate to that of the artificial product in any mixture of the two. (*A. J. P.*, xxxiv. 189.) As a means of distinguishing from the artificial camphor resulting from the reaction between the oil of turpentine and hydrochloric acid, Mr. J. W. Bailey recommends that a drop of alcohol, holding a little of the camphor to be tested in solution, be allowed to evaporate on the slide of a microscope. The crystals then formed produce with polarized light beautiful colors, if of natural camphor, but not if of the artificial. (*Neues Repertorium*, xvi. 763, 1867.)*

and by the action of boiling nitric acid is converted into common camphor. It does not reach European commerce, being largely consumed in the Batta provinces, especially in funeral rites; and any that is exported is bought up at enormous prices for China, where it is especially preferred for embalming purposes on account of its being less volatile than the ordinary drug.

Borneo camphor is also produced in Johore, a province of the Malay peninsula, where it is sold in four qualities. The first is composed of transparent crystals, generally a quarter of an inch and upwards in length; the second of brown crystals, inferior in size; the third of powdery coherent and slightly colored grayish crystals, which resemble Japanese camphor; the fourth quality is brownish, pulverulent, and looks like sea-shore sand. (See *P. J. Tr.*, xvii.)

Ngai camphor is yielded by the *Blumea balsamifera*, which occurs in India, China, Formosa, etc. The crude drug is known to the Chinese as *ngai-fêu*, and when refined in Canton as *ngai-p'ien*. About ten thousand pounds annually are exported from Canton. The refined camphor in appearance, odor, hardness, specific gravity, and volatility agrees almost precisely with Borneo camphor. According to Plowman, it has the chemical composition of Borneo camphor, but differs from it in its alcoholic solution being lævogyrate, and in being converted by boiling nitric acid into a substance thought to be identical with the stearopten of *Chrysanthemum parthenium* Pers.

The physiological action of *Borneo* and *Ngai camphor* and of artificial *borneol* has been studied by R. Stockman (*Journ. of Physiol.*, 1888), who finds that the action of the three substances is practically identical and closely resembles that of true camphor. He finds that these substances act as stimulants to the heart, but that when the dose is sufficiently large there occurs a fall of blood-pressure, apparently due to dilatation of the vessels; that in poisoning the respiration is always very much slowed, apparently by a centric action; that the convulsions which the drug produces are due to an influence upon the cerebral cortex; and that there is a lessening of the functional activity of the spinal cord and of the motor nerves.

* Oil of Camphor. Two substances occur in commerce under the name of oil of camphor: the one derived from the *Camphora officinarum*, known as the *Formosa* or *Japanese Oil of Camphor*, and formerly official under the name of *Oleum camphoræ* in the U. S. P.; the other the product of *Dryobalanops camphora*, the *East India oil of camphor*, not occurring in American and European commerce. The commercial oil of camphor, as found in our markets, is a colorless fluid or of a light yellowish-brown color, having a strong odor precisely like that of camphor, a bitterish camphorous taste, and a specific gravity, according to Prof. Procter, of 0·940. As described by M. Lallemand, the oil of the *Camphora officinarum* is very fluid, scarcely colored, and of a strong smell of camphor. It acts strongly on polarized light, and is dextrogyrate. It has been considered to be simply a mixture of camphor, $C_{10}H_{16}O$, and a hydrocarbon, $C_{10}H_{16}$, but is in reality much more complex. Yoshida (*A. J. P.*, 1886, p. 99) separated it into five portions, as follows: 0·2 per cent. boiling below 145° C.; 7 per cent. of a hydrocarbon boiling at 156° C.; 20 per cent. of a hydrocarbon boiling at 172°–173° C.; 22·8 per cent. of camphor, boiling point 205° C.; 50 per cent. of an oxygenated oil boiling at 212°–213° C. The hydrocarbon boiling at 156° C., Yoshida determined to be *terebinthene*, $C_{10}H_{16}$, which differs in physical respects, however, from the terebinthene of oil of turpentine. The hydrocarbon boiling at 172°–173° C. he found to have a pleasant lemon odor, and, he thinks, is identical with the *citrene* of lemon oil. To the oxygenated oil, which constitutes half of the crude oil, he gives the formula $C_{10}H_{16}O,H_2O$, and calls it *camphorogenol*. Schimmel & Co., of Leipsic, have, since 1885, extracted *safrol* commercially from the Japanese oil of camphor, and they give a different account of its composition. They state (*Bericht von Schimmel & Co.*, April, 1888) that it contains *camphor*, *safrol*, *eugenol*, a *sesquiterpene*, $C_{15}H_{24}$, and possibly *terpinol*. They do not consider Yoshida's camphorogenol to be a distinct substance.

Within the last few years there has appeared in the American and English markets in considerable quantity an oil of camphor produced in Japan. It is imported in tin cans, and varies in tint from the colorless transparency of water, through pale straw, and yellow, to deep black. The specific gravity varies from 0·898 in the colorless oil to 0·990 in the very dark. The oil seems to vary greatly in the amount of camphor it contains, much of it having nearly all the solid principle removed before exportation. The odor is distinctly camphoraceous, with a peculiarity that suggests the odor of sassafras. It is said by Mr. Peter MacEwan to differ from the Formosa oil in its behavior towards nitric acid. If half a drachm of the acid be allowed to act upon half a drachm of Japanese oil, and then diluted with half a drachm of water, a crimson color will be produced. The Formosa oil so treated yields a milky color with a scarcely perceptible green shade; hydrochloric acid gives with each oil a salmon color, more marked, however, with the Japanese oil. For further details, see *P. J. Tr.*, vols. xv., xvi., and *Journ. Chem. Soc.*, Oct. 1885. The oil is said to be used in Japan for the preparation of Chinese ink and varnishes, and for burning. As a diluent for artists' colors it is useful because its capacity for dissolving resins is greater than that of oil of turpentine and similar liquids.

The Formosa camphor oil industry, owing to onerous trade restrictions, has decreased greatly (*Journ. Soc. Chem.*

Medical Properties and Uses. Camphor does not seem to have been known to the ancient Greeks and Romans. Europe probably derived it from the Arabians, by whom it was employed as a refrigerant. The local action of camphor is that of an irritant, with probably a benumbing influence upon the peripheral nerves of the mucous membrane. It is readily absorbed, and is finally eliminated from the kidneys, chiefly in the form of campho-glycuronic acid. When taken in moderate dose it produces in health a feeling of warmth in the stomach, some increase in the frequency, the force, and the fulness of the pulse, and a slight mental exhilaration. According to the older authorities, it may also cause distinct sexual excitement with voluptuous dreams, but such observation can rarely be corroborated, and in clinical medicine the drug has been used in full dose to a considerable extent as an antaphrodisiac and sexual sedative. After larger doses there are lassitude, decrease in the frequency of the pulse, and giddiness, preceded it may be by a short period of excitement. The symptoms produced by poisonous doses are: faintness, headache, vertigo, confusion of ideas, burning pain in the stomach, delirium, violent convulsions, insensibility, general paralysis; a pulse generally small, but sometimes accelerated and sometimes lowered in number; a skin cool, pale, or livid, generally bedewed with sweat. Sudden unconsciousness, with or without convulsions, has been in some instances the first manifestation of the action of the poison, and of course in any individual case many of the symptoms detailed above may be wanting. So far as we know, there are on record only three fatal cases of poisoning.

The chief influences of the therapeutic dose of camphor are exerted upon the nervous system, and the drug has been largely used as an antispasmodic and stimulant in various diseases of a typhoid character, when there is a frequent irritated pulse, a dry skin, and much nervous derangement, indicated by restlessness, watchfulness, tremors, subsultus, and low muttering delirium. In the United States, however, it is at present not much used in serious disease, but is very extensively employed in various functional nervous disorders, such as *hysteria*, *dysmenorrhœa*, *general nervousness*, and even in *nymphomania*. It is much used in *serous diarrhœa*, in *flatulence*, *spasmodic colic*, etc., as a local stimulant to the alimentary canal. In some of these cases much advantage may be derived from combining it with opium.

In Germany camphor is used to a considerable extent as a cardiac and general stimulant, not only in adynamic fevers but also when there is acute cardiac failure, and recent experiments show that the drug has a decided influence upon the circulation, indicating that in small doses it directly stimulates the heart and also widens the blood-paths by acting upon the vasomotor centre, and that in toxic doses it depresses both the heart and the arteries.

Camphor is much used locally as an anodyne, dissolved in alcohol, oil, or acetic acid, and frequently combined with laudanum. In *rheumatic* and *gouty affections*, and various internal spasmodic and inflammatory complaints, it often yields relief in this way. It is stated that the *ardor urinæ* of gonorrhœa may be alleviated by injecting an oleaginous solution of camphor into the urethra, and the *tenesmus* from ascarides and dysentery by enemata of the same solution. Twenty or thirty grains of camphor, added to a poultice, and applied to the perineum, allay the *chordee* which is a painful attendant upon gonorrhœa. Its vapor has been inhaled into the lungs with benefit in *asthma* and *spasmodic cough;* and a lump of it held to the nose is said to relieve *coryza*. It has been employed for the same purpose, and for *nervous headache*, in the form of powder snuffed up the nostrils. It enters into the composition of certain tooth-powders.

Camphor is frequently given in the form of pill, and when the dose is not large, in spite of its slow solubility and irritant properties, the drug is well tolerated. When, however, it is desired to give very large doses or to have a prompt effect, a liquid preparation is preferable.

Ind., 1887, 391), while that of Japan has increased enormously. In 1885 the exportation from Japan was 225,200 kilos, in 1886, 537,700 kilos, and in 1887 much more; but on account of the failure of price the Japanese have consumed most of the oil they produce, the importation into the United States in 1892 having decreased to but a little more than one-fourth of what it formerly was.

The oil of camphor has properties similar to those of camphor, but more stimulant, and is especially applicable to affections of the stomach and bowels in which an anodyne and stimulant impression is indicated, as *flatulent colic* and *spasmodic cholera*. It may also be used externally, as a rubefacient and anodyne liniment, diluted with soap liniment, or olive oil, in *local rheumatism* and *neuralgic pains*, *bruises*, *sprains*, etc. The dose is two or three drops (0·12 to 0·18 C.c.).

The *Dryobalanops oil of camphor* is said to be found in trees too young to produce camphor, and is supposed to constitute the first stage in the development of this substance, as it occupies the cavities in the trunk which are afterwards filled with the camphor. The chief constituent of it is a peculiar volatile oil, which is termed *borneene*, is isomeric with oil of turpentine, $C_{10}H_{16}$, and holds in solution borneol and resin. By fractional distillation this oil may be separated into two portions, the one more volatile than the other, but not differing in composition.

The Aqua Camphoræ of the U. S. Pharmacopœia is an excellent but feeble preparation. The Spiritus Camphoræ may be given in milk or even in water, although under the latter circumstances it is apt to adhere to the sides of the vessel or of the spoon. An excellent method of administration is afforded by an emulsion made by rubbing up the camphor with mucilage of acacia and water. As camphor is freely soluble in chloroform, when it is desired to give the two remedies together the camphor may be dissolved in the chloroform and administered in milk or in emulsion. *Oleum camphoratum* of the German Pharmacopœia is made by dissolving one part of camphor in nine parts of olive oil, and is much used in Germany hypodermically as a cardiac stimulant in *collapse*. According to Schilling, as much as thirty grains of the camphor may be thus administered without disagreeable results. The medium dose of camphor is from five to ten grains (0·33–0·65 Gm.); but, to meet various indications, it may be diminished to a single grain (0·065 Gm.) or increased to a scruple (1·3 Gm.). There is no known antidote to camphor, and in poisoning by it, after evacuation of the stomach and bowels, the symptoms must be met as they arise.

CAMPHORA MONOBROMATA. U. S. Monobromated Camphor.

$C_{10}H_{15}BrO$; 230·42. (CĂM′PHỌ-RẠ MŌN-Ọ-BRŌ-MĀ′TẠ.) $C_{10}H_{15}BrO$; 230·8.

Bromated Camphor, Brominated Camphor, Brom-camphor; Camphre monobromé, *Fr.;* Monobrom Camphor, *G.*

This substance was discovered in 1861 by Th. Swarts, who prepared it by heating bibromide of camphor in a sealed tube to 100° C. It may also be made by heating for three hours in a sealed tube, with the water-bath, bromine and camphor in the proper chemical proportions. The crystalline mass is washed with water, recrystallized from alcohol after treatment with animal charcoal, washed with an alcoholic solution of potassa, then with much water, and finally recrystallized from a mixture of alcohol and ether. It is very easy to prepare the monobromide on a small scale in this way. There is, however, at all times a very great pressure upon the inside of the tube, and the attempt to practise the method upon a large scale is very apt to result in shattering the tubes. This has led to numerous experiments as to the best method of preparing it. For methods of preparing bromocamphor and allied products, see *Chem. News*, 1896, 208. Prof. Maisch (*A. J. P.*, 1872, 339) introduces 4 oz. of bromine gradually into a retort in which 13 oz. of camphor have been previously placed. In 15 or 20 minutes a brisk reaction will commence. When this subsides, 8 or 9 oz. more of bromine are to be poured in, in four portions, waiting after each addition until the reaction ceases. The liquid in the retort is now to be heated to about 132° C. (270° F.), then cooled, and sufficient petroleum benzin added to dissolve the crystalline mass. The crystals which are formed on cooling may be purified by recrystallization from benzin or hot alcohol. Various modifications of this process have been proposed. Prof. J. U. Lloyd (*A. J. P.*, April, 1875) directs the addition of water to the camphor and bromine in the retort, and boils the mixture for two hours, or until all the water is evaporated. Then the contents are poured into a dish and treated with warm alcohol, and allowed to crystallize, the mother-liquor being drained off and recrystallized from hot alcohol. C. C. Keller (*Schweiz. Wochensch. f. Pharm.*, 1880, p. 50) uses chloroform (instead of water, as proposed by Prof. Lloyd) with the camphor and bromine, and washes the crystals with absolute alcohol, crystallizing them finally from an ethereal solution. 300 parts of camphor yield 340 parts of monobromated camphor.*

Properties. "Colorless, prismatic needles or scales, having a mild, camphoraceous odor and taste, permanent in the air, unaffected by light, and neutral to litmus paper. Almost insoluble in water; freely soluble in alcohol, ether, chloroform, hot benzin, and fixed and volatile oils; slightly soluble in glycerin. It is also soluble, without decomposition, in cold, concentrated sulphuric acid, from which it separates again unaltered, when the solution is poured into water. It melts at 76° C. (168·8° F.), and sublimes at a slightly higher temperature. At 274° C. (525·2° F.) it boils without decomposition, and is finally volatilized without leaving a residue." *U. S.*

Medical Properties. Monobromated camphor was first proposed as a medicine by Professor Deneffe, and has been used as a nervous sedative in *delirium tremens*, *hysteria*, *convulsive irritation* of teething, *sleeplessness*, etc. According to the experiments of Dr. Bourneville (*Le Progrès Médical*, 1874) and of Dr. Lawson (*The Practitioner*, Aug. 1874), it produces in

* *Chlorinated Camphor* ($C_{10}H_{15}Cl.O$), the counterpart of monobromated camphor, has been studied physiologically by F. Perrenot under the name of *Chlorure de Camphre* (*Thèse*, Lyon, 1886). He finds that it is not poisonous, but has distinct antiseptic properties, and recommends it as a substitute for iodoform and other antiseptics when ulcerated surfaces need a stimulant dressing.

mammals muscular weakness, passing into paralysis, very decided progressive reduction of temperature, decrease in the respiration rate, sleep passing into stupor, and finally death. Dr. Bourneville states that the vessels of the ear and eyelids in the rabbit are contracted. Its therapeutic action resembles, but is not identical with, that of other bromides; in the experience of Dr. H. C. Wood, it has seemed to be of especial value in *spermatorrhœa.* It is not safe to give it too freely, as in some cases its ingestion has been followed by epileptiform convulsions. The dose of it is 5 grains (0·33 Gm.),* given in pill or emulsion, and repeated every hour for 2 or 3 doses if necessary. The emulsion may be made by dissolving it in six times its weight of expressed oil of almonds, and then forming an emulsion with gum and water in the usual manner.

CANNABIS INDICA. U. S., Br. Indian Cannabis. [Indian Hemp.]

(KĂN'NA-BĬS ĬN'DI-CA.)

"The flowering tops of the female plant of Cannabis sativa, Linné (nat. ord. Urticaceæ), grown in the East Indies." *U. S.* "The dried flowering or fruiting tops of the female plant of Cannabis sativa, Linn., grown in India; from which the resin has not been removed." *Br.*

Hemp, Indian Hemp; Herba Cannabis Indicæ; Chanvre Indien, *Fr.;* Indischer Hanf, *G.*

Gen. Ch. MALE. *Calyx* five-parted. *Stamens* five. FEMALE. *Calyx* one-leaved, rolled up. *Styles* two. *Lindley.*

Cannabis sativa. Linn. *Sp. Plant.* 1457; Griffith, *Med. Bot.* p. 572; *B. & T.* 231. Hemp is an annual plant, from four to eight feet or more in height, with an erect, branching, angular stem. The leaves are alternate or opposite, on long, lax footstalks, roughish, and digitate, with linear-lanceolate, serrated segments. The stipules are subulate. The flowers are axillary; the male in long, branched, drooping racemes; the female in erect, simple spikes. The stamens are five, with long pendulous anthers; the pistils two, with long, filiform, glandular stigmas. The fruit is ovate and one-seeded. The whole plant is covered with a fine pubescence, scarcely visible to the naked eye, and somewhat viscid to the touch. The hemp plant of India, from which the drug is derived, has been considered by some as a distinct species, and named *Cannabis indica;* but the most observant botanists, upon comparing it with our cultivated plant, have been unable to discover any specific difference. It is now, therefore, regarded merely as a variety, and is distinguished by the epithet *indica.* Dr. Pereira states that in the female plant the flowers are somewhat more crowded than in the common hemp, but that the male plants in the two varieties are in all respects the same.

C. sativa is a native of the Caucasus, Persia, and the hilly regions in the north of India. It is cultivated in many parts of Europe and Asia, and largely in our Western States. It is from the Indian variety exclusively that the medicine was formerly obtained; the heat of the climate in Hindostan apparently favoring the development of its active principle.† Dr. H. C. Wood, having obtained a parcel of the male plant of *C. americana* from Kentucky, made an alcoholic extract of the leaves and tops, and, upon trying it on the system, found it effective in less than a grain, and, having inadvertently taken too large a dose, experienced effects which left no doubt of the powers of the medicine, and of the identity of its influence with that of the Indian plant. How far the female tops might have the same effect is left uncertain; but, if we are to judge from analogy with the Indian plant, they would be preferable to the male. (*Proc. Am. Philos. Soc.*, vol. xi. p. 226.) The results obtained by Dr. Wood were so decisive that at the 1880 revision of our Pharmacopœia the American plant was recognized; but in 1890 it was dropped.

* *Elixir of Monobromated Camphor* is proposed by Munday (*P. J. Tr.*, March 3, 1877). Monobromated camphor 3 parts, alcohol (90 per cent.) 120 parts, orange-flower water 80 parts, glycerin 100 parts. Mix the alcohol and glycerin; dissolve the monobromated camphor by the use of a gentle heat, and add the orange-flower water. It contains 1 per cent. of monobromated camphor.

† On a visit to the botanical garden of Edinburgh, in the autumn of 1860, Dr. George B. Wood saw a full-grown specimen of *Cannabis sativa,* and was surprised to find that it was only about four feet high, had little or no odor, and was scarcely adhesive when handled. If this is the general character of the hemp plant in the north of Europe, it is not surprising that it should be destitute of the medicinal properties of the Indian plant. In Philadelphia the plant attains a height usually of six or eight feet, has a decided narcotic odor, and exudes so much of its peculiar resin as to be very adhesive to the fingers. On this occasion Dr. Christison informed Dr. Geo. B. Wood, from information he had received from India, that the plant there cultivated in the hot plains does not yield hashish satisfactorily, but that this product is chiefly if not exclusively obtained from it in the hilly regions. He said, moreover, that the story of the natives running through the hemp-fields and collecting the resin on their clothing, from which it is afterwards scraped, is, if not quite untrue, at least apocryphal. He had been informed that the real mode of gathering it is to rub the hemp-tops between the hands, and, when the palms and fingers are sufficiently loaded with the resin, to scrape it off. It is possible, however, that different methods may be followed in different localities.

The seeds, though not now official have been used in medicine. They are about the eighth of an inch long, roundish-ovate, somewhat compressed, of a shining ash-gray color, and of a disagreeable, oily, sweetish taste. They yield by expression about 20 per cent. of a fixed oil, which has the drying property, and is used in the arts. They contain also uncrystallizable sugar and albumen, and when rubbed with water form an emulsion, which may be used advantageously in inflammations of the mucous membranes, though without narcotic properties. The seeds are much used as food for birds, as they are fond of them. They are generally believed to be in no degree poisonous; but M. Michaud relates the case of a child in whom serious symptoms of narcotic poisoning occurred after taking a certain quantity of them. It is probable that some of the fruit eaten by the child was unripe, as in this state it would be more likely to partake of the peculiar qualities of the plant. (*Annuaire de Thérap.*, 1860.)

In Hindostan, Persia, and other parts of the East, hemp has long been habitually employed as an intoxicating agent. The parts used are the tops of the plant, and a resinous product obtained from it. *Ganja* or *gunjah* is the tops of cultivated female plants, cut whilst unfertilized directly after flowering, and formed into bundles from two to four feet long by three inches in diameter. The utmost care is taken to prevent fertilization, it being affirmed that a single male plant will spoil a whole field. When hemp is cultivated in India for its fibre or seed, male and female plants are grown together. The *hashish* of the Arabs is essentially the same as gunjah. For a description of the method employed in India for the preparation of hasheesh or *majoom*, see *Proc. A. P. A.*, 1897, 417. The name *bang* is given to a mixture of the larger leaves and capsules, without the stems, of wild plants, male and female. There is on the surface of the plant a resinous exudation, to which it owes its clammy feel. Men clothed in leather run through the hemp-fields, brushing forcibly against the plants, and thus separating the resin, which is subsequently scraped from their dress and formed into balls. These balls and also masses formed out of resin mechanically separated from gunjah bundles are called *churrus*. In these different states of preparation the hemp is smoked like tobacco, with which it is said to be frequently mixed. *Momea* or *mimea* is a hemp preparation said to be made in Thibet with human fat. An infusion or decoction of the plant is also sometimes used as an exhilarating drink. From gunjah the Messrs. Smith, of Edinburgh, obtained a purer resin by the following process. Bruised gunjah is digested, first in successive portions of warm water, till the expressed liquid comes away colorless; and afterwards for two days, with a moderate heat, in a solution of sodium carbonate, containing one part of the salt for two of the dried herb. It is then expressed, washed, dried, and exhausted by percolation with alcohol. The tincture, after being agitated with milk of lime containing one part of the earth for twelve of the gunjah used, is filtered; the lime is precipitated by sulphuric acid; the filtered liquor is agitated with animal charcoal, and again filtered; most of the alcohol is distilled off, and to the residue twice its weight of water is added; the liquor is then allowed to evaporate gradually; and, finally, the resin is washed with fresh water until it ceases to impart a sour or bitter taste to the liquid, and is then dried in thin layers. Thus obtained, it retains the odor and taste of the gunjah, which yields from 6 to 7 per cent. of it.

Properties. Fresh hemp has a peculiar narcotic odor, which is said to be capable of producing vertigo, headache, and a species of intoxication. It is much less in the dried tops, which have a feeble bitterish taste. According to Dr. Royle, *churrus* is when pure of a blackish-gray, blackish-green, or dirty olive color, of a fragrant and narcotic odor, and a slightly warm, bitterish, and acrid taste. The Indian hemp is officially described as "branching, compressed, brittle, about 5 Cm. or more long, with a few digitate leaves, having linear-lanceolate leaflets, and numerous, sheathing, pointed bracts, each containing two small, pistillate flowers, sometimes with the nearly ripe fruit, the whole more or less agglutinated with a resinous exudation. It has a brownish-green color, a peculiar, narcotic odor, and a slightly acrid taste." *U. S.* "The fruit is one-seeded and supported by an ovate-lanceolate bract. Both leaves and bracts bear external oleo-resin glands and one-celled curved hairs, the bases of which are enlarged and contain cystoliths." *Br.* For a histological description of the leaf by Dr. A. R. L. Dohme, see *Proc. A. P. A.*, 1897, 569. Schlesinger found in the leaves a bitter substance, chlorophyll, green resinous extractive, coloring matter, gummy extract, extractive, albumen, lignin, and salts. The plant also contains volatile oil in very small proportion, which probably has narcotic properties. The resin obtained by T. & H. Smith, of Edinburgh, in 1846, has been thought to be the active principle, and has received the name of *cannabin*. It is neutral, soluble in alcohol and ether, and separable from the alcoholic solution by water as a white precipitate. Martino (*N. Rep. Pharm.*, 4, 529) obtained a resin fusing at 68° C. (154·4°

F.), easily soluble in alcohol, ether, and volatile oils, difficultly soluble in aqueous alkalies and acids. By oxidation with nitric acid a product is formed, *oxycannabin*, $C_{20}H_{20}H_2O_7$, which, after purification, is white and crystalline. Preobraschensky (*Pharm. Zeit. f. Russl.*, 1876, 705) believes that cannabis indica contains the alkaloid nicotine; and this may sometimes be found in some samples of hasheesh intended for smoking, which contain tobacco as an admixture. From the effects on the system of the exhalations from fresh hemp, it was a very probable supposition that the plant owed its medical properties, in part at least, to a volatile principle. By repeated distillation of the same portion of water from relatively large quantities of hemp renewed at each distillation, M. J. Personne obtained a volatile oil, of a stupefying odor, and an action on the system such as to dispose him to think that it was the active principle of the plant. As the water distilled was strongly alkaline, he supposed that this volatile principle might be a new alkaloid; but the alkaline reaction was found to depend on ammonia; and the liquid obtained proved to be a volatile oil, lighter than water, of a deep amber color, a strong smell of hemp, and composed of two distinct oils, one colorless, with the formula $C_{18}H_{20}$, the other a hydride of the first, $C_{18}H_{22}$, which was solid, and separates from alcohol in plate-like crystals. For the former M. Personne proposes the name of *cannabene*. It is affirmed that when this is inhaled, or taken into the stomach, a singular excitement is felt throughout the system, followed by a depression, sometimes amounting to syncope, with hallucinations which are generally disagreeable, but an action on the whole slighter and more fugitive than that of the resin. Siebold and Bradbury (*Year-Book of Pharmacy*, 1881), by the process for nicotine, obtained *cannabinine* in the form of a varnish-like dry mass, which they assert is an alkaloid. Dr. Matthew Hay believes that there are several alkaloids in cannabis indica, and he has obtained one, *tetano-cannabene*, whose existence is made very doubtful by the researches of Warden and Waddell (*Indian Med. Gazette*, xix.) and of Jahns (*P. J. Tr.*, 1883). Henry F. Smith has also found an alkaloid corresponding to that described by Siebold and Bradbury. He obtained a yellowish-green, transparent, varnish-like mass, which had a strong, peculiar odor, resembling that of coniine, and formed a crystalline sulphate. (*A. J. P.*, 1891, 387.)* *Cannabine tannate* is now an article of commerce and made by Merck; it is asserted by Dr. Dornmüller to have soporific effects, but Dr. H. C. Wood has found it to be physiologically inert. Bombelon prepares pure *cannabine* by decomposing the tannate with zinc oxide and extracting the cannabine as a greenish-brown, non-adhesive powder, which he asserts is more reliable than the tannate. (*Amer. Drug.*, 1884, 132.) *Cannabindon*, $C_8H_{12}O$, is a dark red syrupy liquid obtained by Kobert (*Chem. Zeit.*, 1894, 741) from Cannabis Indica; it is soluble in alcohol, ether, and oils; it is affirmed to be narcotic in doses of from half a grain to two grains (0·03 to 0·1 Gm.). Marino-Zuco and Vignolo (*Gazetta Clinica Italiana*, 1895, Part I., 262) have obtained an alkaloidal substance which forms a colorless deliquescent crystalline hydrochloride, having a powerful cardiac depressant effect. It is supposed, however, to represent a decomposition product of the original plant principle. As a result of a reinvestigation of charas (churrus) from Indian hemp, Wood, Spivey, and Easterfield (*Journ. Chem. Soc.*, vol. lxix. 539) have found the following principles: 1, a *terpene*, boiling between 150° and 180° C.; 2, a *sesqui-terpene*, boiling at 258°–259° C.; 3, a *crystalline paraffin* of probable formula $C_{29}H_{60}$, melting at 63·5° C.; and 4, a *red oil*, boiling at 265°–270° C. under a pressure of 20 Mm., to which they give the name *cannabinol*, and the formula $C_{18}H_{24}O_2$. This latter constituent they consider the only active ingredient. It is probably the same substance as the dark red syrup of Kobert, mentioned above under the name cannabindon. The authors found that cannabinol readily underwent superficial oxidation, at the same time losing its toxic activity.

Medical Properties. Extract of hemp is a powerful narcotic, causing exhilaration, intoxication, delirious hallucinations, and, in its subsequent action, drowsiness and stupor, with little effect upon the circulation. It is asserted also to act as a decided aphrodisiac, to increase the appetite, and occasionally to induce the cataleptic state. In overdoses it may produce poisonous effects. In morbid states of the system it has been found to cause sleep, to allay spasm, to compose nervous disquietude, and to relieve pain. In these respects it resembles opium; but it differs from that narcotic in not diminishing the appetite, checking the secretions, or constipating the bowels. It is much less certain in its effects, but may sometimes be preferably employed, when opium is contra-indicated by its nauseating or constipating effects,

* Dr. I. Roux (*Arch. d. Pharm.*, 1887) has experimented upon extracts made by treating purified extract of hemp with petroleum benzin and ether. The ether extract produced insignificant results. The petroleum extract was excitant and convulsivant. The alcoholic extract was a feeble narcotic.

or its disposition to produce headache, and to check the bronchial secretion. The complaints in which it has been specially recommended are *neuralgia*, *gout*, *rheumatism*, *tetanus*, *hydrophobia*, *epidemic cholera*, *convulsions*, *chorea*, *hysteria*, *mental depression*, *delirium tremens*, *insanity*, and *uterine hemorrhage*. Dr. Alexander Christison, of Edinburgh, affirms that it has the property of hastening and increasing the contractions of the uterus in delivery, and has employed it with advantage for this purpose. It acts very quickly, and without anæsthetic effect. It appears, however, to exert this influence only in a certain proportion of cases. (*Ed. Month. Journ. of Med. Sci.*, xiii. 117; xv. 124.) The strength of the extract varies much as found in commerce, and therefore no definite dose can be fixed. When it is of good quality, half a grain or a grain (0·03–0·065 Gm.) will affect the system, whilst some apparently good extracts are practically inert. The proper plan is to begin with one-quarter grain (0·016 Gm.), repeated at intervals of two, three, or four hours, and gradually increased until its influence is felt, and the strength of the parcel employed is thus ascertained. Afterwards the dose should be regulated by the ascertained strength; but, should a new parcel be employed, the same caution must be observed as to the commencing dose. A tincture is prepared by dissolving an ounce of the extract in a pint (Imp. meas.) of alcohol. A dose of this, equivalent to a grain of the extract, is about twenty minims (1·25 C.c.), or forty drops. According to Mr. C. R. Marshall (*London Lancet*, i., 1897; also *Journ. Amer. Med. Assoc.*, Oct. 1898), upon dogs and cats cannabinol acts as a powerful hypnotic, producing also ataxia and other evidences of action upon the nerve-centres. Its influence upon the circulation was found to be very feeble, though excessive doses reduced the pulse-rate. In man, doses of from one and a half to two grains of cannabinol produced very active intoxication, with symptoms similar to those caused by cannabis indica. The inertness of much of the commercial extract Marshall believes to be due to the proneness of cannabinol to undergo oxidation. Of the terpenes of cannabis indica, Marshall took as high as eight minims without effect.

CANTHARIS. U. S., Br. Cantharides. [Spanish Flies.]

(KĂN'THA-RĪS.)

"Cantharis vesicatoria, De Geer (class, Insecta; order, Coleoptera). Cantharides should be thoroughly dried at a temperature not exceeding 40° C. (104° F.), and kept in well-closed vessels." *U. S.* "The dried beetle, Cantharis vesicatoria, Latr." *Br.*

Cantharides, *P.G.;* Muscæ Hispanicæ; Cantharides, Cantharide, *Fr.;* Spanische Fliege, Kantharide, Cantharide, *G.;* Cantarelie, *It.;* Cantaridas, *Sp.*

The term *Cantharis* was employed by the ancient Greek writers to designate many coleopterous insects or beetles. Linnæus gave the title to a genus not including the official blistering insect, and placed this in the genus *Meloë*, which, however, has been since divided into several genera. Geoffrey made the Spanish fly (beetle) the prototype of a new genus, *Cantharis*, substituting *Cicindela* as the title of the Linnæan genus. Fabricius altered the arrangement of Geoffrey, and substituted *Lytta* for *Cantharis* as the generic name. The former was adopted by the London College, and at one time was in extensive use; but the latter, having been restored by Latreille, is now recognized in the British and U. S. Pharmacopœias, and is universally employed. By this naturalist the vesicating insects were grouped in a small tribe, corresponding very nearly with the Linnæan genus Meloë, and distinguished by the title *Cantharidæ*. This tribe he divided into eleven genera, among which is Cantharis. Two others of these genera, *Meloë* properly so called, and *Mylabris*, have been employed as vesicatories. *Mylabris cichorii* is thought to be one of the insects described by Pliny and Dioscorides under the name of cantharides, and is to this day employed in Italy, Greece, the Levant, and Egypt; and another species, *M. pustulata*, is used for the same purpose in China. Mr. W. R. Warner has found 500 parts of *M. cichorii* to yield 2·13 parts of cantharidin, which somewhat exceeds the yield of Spanish flies (*A. J. P.*, xxviii. 195); and R. Wolff has obtained by ethereal extraction more than 4 parts of cantharidin in 500 of the *Lytta aspersa* of Buenos Ayres. The *M. cichorii* has been recently imported to some extent under the name of *Chinese blistering fly*. It is black, with the powder blackish gray and free from shining particles; it yielded to Prof. Maisch (*Proc. Amer. Pharm.*, 1872) 1·016 per cent., and to L. Fahnestock 1·25 per cent., of cantharidin (*A. J. P.*, 1879). For further account of non-official blistering flies, see page 312.

CANTHARIS. *Class* Insecta. *Order* Coleoptera. *Linn.—Family* Trachelides. *Tribe* Cantharidæ. *Latreille.*

Gen. Ch. Tarsi entire; *nails* bifid; *head* not produced into a rostrum; *elytra* flexible, covering the whole abdomen, linear, semicylindric; *wings* perfect; *maxillæ* with two membranous *laciniæ*, the external one acute within, subuncinate; *antennæ* longer than the head and thorax,

rectilinear; first joint largest, the second transverse, very short; *maxillary palpi* larger at tip. (*Say.*)

Cantharis vesicatoria. Latreille, *Gen. Crust. et Insect.*, ii. p. 220. This beetle is from six to ten lines in length, by two or three in breadth, and of a beautiful, shining, golden-green color. The head is large and heart-shaped, bearing two thread-like, black, jointed feelers; the thorax short and quadrilateral; the wing-sheaths long and flexible, covering brownish membranous wings. When alive, the Spanish flies have a strong, penetrating, fetid odor, compared to that of mice, by which swarms of them may be detected at a considerable distance. They attach themselves preferably to certain trees and shrubs, such as the white poplar, privet, ash, elder, and lilac, upon the leaves of which they feed. They abound most in Spain, Italy, and the south of France, but are found also in all the temperate parts of Europe, and in the west of Asia. According to the researches of Lichtenstein, the eggs are laid by the female in the latter part of June in small cylindrical holes made in the ground. A week later the larvæ hatch out. They are a millimeter long, with two long caudal threads, and of a brown color. After many efforts, M. Lichtenstein succeeded in getting them to feed on the honey contained in the stomach of bees. In a few days they changed into milk-white larvæ, and about a month after this buried themselves in the ground, to assume the chrysalis stage and to hatch out the following spring as perfected beetles. In the wild state the larvæ are said to mount up flowers and attach themselves to bees or other hymenopterous insects; carried by the bee to the hive, the larvæ feed upon the young bees and the honey and bee-bread stored up for use. The beetles usually make their appearance in swarms upon the trees in May and June, when they are collected. The time preferred for the purpose is in the morning, at sunrise, when they are torpid from the cold of the night, and easily let go their hold. Persons with their faces protected by masks, and their hands with gloves, shake the trees, or beat them with poles; and the insects are received as they fall upon linen cloths spread underneath. They are then plunged into vinegar diluted with water, or exposed in sieves to the vapor of boiling vinegar, and, having been thus deprived of life, are dried either in the sun, or in apartments heated by stoves. This mode of killing the flies by the steam of vinegar is as ancient as the times of Dioscorides and Pliny. In some places they are gathered by smoking the trees with burning brimstone. It has been proposed by M. Lutrand to destroy them by the vapor of chloroform. When perfectly dry, they are introduced into casks or boxes lined with paper and carefully closed, so as to exclude as much as possible the atmospheric moisture. According to M. Neutwich, the young fly has no vesicating power (*P. J. Tr.*, Nov. and Dec., 1870, p. 355); but this is denied by H. Beauregard. (*Ibid.*, xv. 873.)

Cantharides come chiefly from Spain, Italy, Sicily, and other parts of the Mediterranean. Considerable quantities are also brought from St. Petersburg, derived originally, in all probability, from the southern provinces of Russia, where the insect is very abundant. The Russian flies are most esteemed. They may be distinguished by their greater size, and their color approaching to that of copper.

In the United States are several species of Cantharis, which have been employed as substitutes for *C. vesicatoria* and found equally efficient; but none of them are now recognized by our national Pharmacopœia; even *C. vittata*, which was at one time official, having been discarded.*

* *Blistering Flies not official.* 1. *Cantharis vittata.* Latreille, *Gen. Crust. et Insect.*; Durand, *Journ. of the Phila. Coll. of Pharm.*, ii. 274, fig. 4. The *potato fly** is rather smaller than *C. vesicatoria*, which it resembles in shape. Its length is about six lines. The head is light red, with dark spots upon the top; the feelers are black; the elytra or wing-cases are black, with a yellow longitudinal stripe in the centre, and with a yellow margin; the thorax is also black, with three yellow lines; and the abdomen and legs, which have the same color, are covered with a cinereous down. It inhabits chiefly the potato vine, and appears about the end of July or beginning of August, in some seasons very abundantly. It is found on the plant in the morning and evening, but during the heat of the day descends into the soil. The insects are collected by shaking them from the plant into hot water, and are afterwards carefully dried in the sun. They are natives of the Middle and Southern States. This species of Cantharis was first described by Fabricius in the year 1781, and was introduced to the notice of the profession by Dr. Isaac Chapman, of Bucks County, Pennsylvania, who found it equal if not superior to the Spanish fly as a vesicatory. The testimony of Dr. Chapman has been corroborated by that of many other practitioners. It may be applied to the same purposes, treated in the same manner, and given in the same dose as the foreign insect. Mr. W. R. Warner obtained 1·99 parts of cantharidin from 500 parts of this beetle, but by improved methods Mr. Fahnestock procured 1½ per cent. of the active principle. (*A. J. P.*, xxviii. 195; li. 298.) According to the researches of Prof. Jos. Leidy, the vesicating principle resides in the blood, the eggs, and a peculiar fatty matter of certain accessory glands of the generative apparatus (*Am. Jour. of Med. Sci.*, Jan. 1860, p. 60); whilst H. Beauregard (*P. J. Tr.*, xv. 873) found

* According to the researches of L. Dembinski, the *Colorado potato-beetle*, or "potato bug" (*Doryphora decemlineata*), contains no cantharidin. (*A. J. P.*, 1877, p. 550.)

Properties. "About 25 Mm. long and 6 Mm. broad; flattish-cylindrical, with filiform antennæ, black in the upper part, and with long wing-cases and ample membranous, transparent, brownish wings; elsewhere of a shining, coppery-green color. The powder is grayish-brown, and contains green, shining particles. Odor strong and disagreeable; taste slight, afterwards acrid." *U. S.* Dried Spanish flies preserve the form and color, and, to a certain extent, the disagreeable odor, of the living insect. They have an acrid, burning, and urinous taste. Their powder is of a grayish-brown color, interspersed with shining green particles, which are the fragments of the feet, head, and wing-cases. If kept perfectly dry, in well-stopped glass bottles, they retain their activity for a great length of time. A portion which had been preserved by Van Swieten for thirty years, in a glass vessel, was found still to possess vesicating properties. But exposed to a damp air they quickly undergo putrefaction; and this change takes place more speedily in the powder. Hence the insects should either be kept whole, and powdered as they are wanted for use, or, if kept in powder, should be well dried immediately after pulverization, and preserved in air-tight vessels. They should never be purchased in powder, as, independently of the consideration just mentioned, they may in this state be more easily adulterated. But, however carefully managed, cantharides are apt to be attacked by mites, which feed on the interior soft parts of the body, reducing them to powder, while the hard exterior parts are not affected. An idea was at one time prevalent that the vesicating

that the blood, the seminal vesicules of the male, the eggs, and all parts of the generative organs of the female are active.

2. *Cantharis cinerea.* Latreille, *Gen. Crust. et Insect.;* Durand, *Journ. of the Phila. Coll. of Pharm.*, ii. 274, fig. 5. The *ash-color cantharis* closely resembles the preceding species in figure and size, but differs from it in color. The elytra and body are black, without the yellow stripes that characterize *C. vittata*, and are entirely covered with a short and dense ash-colored down, which conceals the proper color of the insect. The feelers are black, and the first and second joints are very large in the male. This species also inhabits the potato plant, and is occasionally found on other plants, as the English bean and wild indigo. It is a native of the Northern and Middle States. Illiger in 1801 discovered its vesicating properties; but Dr. Gorham was first to call public attention particularly to the subject, and to the fact of its equality in all respects with the potato fly, in a communication addressed, in the year 1808, to the Medical Society of Massachusetts.

3. *Cantharis marginata.* Latreille, *Gen. Crust. et Insect.;* Durand, *Journ. of the Phila. Coll. of Pharm.*, ii. 274, fig. 6. This is somewhat larger than *C. vittata*, and of a different shape. The elytra are black, with the suture and margin ash-colored. The head, thorax, and abdomen are black, but nearly covered with an ash-colored down; and on the upper part of the abdomen, under the wings, are two longitudinal lines of a bright clay color. The insect is usually found, in the latter part of summer, upon different species of Clematis, and frequents especially the lower branches which trail along the ground. Professor Woodhouse, of Philadelphia, first ascertained its vesicating properties; but it had previously been described by Fabricius as a native of the Cape of Good Hope. Dr. Harris, of Massachusetts, found it as efficient as any other species.

4. *Cantharis atrata.* Latreille, *Gen. Crust. et Insect.;* Durand, *Journ. of the Phila. Coll. of Pharm.*, ii. 274, fig. 7. The *black cantharis* is smaller than the indigenous species already described, but resembles *C. marginata* in figure. Its length is only four or five lines. It is distinguished by its size, and its uniform black color. It frequents more especially the different species of Aster and Solidago, though it is found also on *Prunella vulgaris*, *Ambrosia trifida*, and some other plants. Mr. Durand met with considerable numbers of this insect near Philadelphia, in the month of September; and they continued to appear till the middle of October. They are common in the Northern and Middle States, but are not confined exclusively to this country, being found also in Barbary. Drs. Oswood and Harris, of New England, satisfactorily ascertained their vesicating powers. They are probably identical with the insect noticed as vesicatory by Prof. Woodhouse, under the name of *Meloë niger*.

5. *Cantharis vulnerata.* Harrison Allen, *Medical Zoology*, 1st ed., p. 150. Dr. Geo. H. Horn states that this is so abundant upon the Pacific coast that he has often seen bushels of it covering the ground. It has a black body, an orange-colored head, sometimes with a broad black stripe down the middle, and black wing-cases. Dr. Horn found it medicinally very active, as was also the less plentiful *C. melæna*.

Several other species have been discovered in the United States, but not yet practically employed. Among these are *C. æneas*, a native of Pennsylvania, discovered by Mr. Say; *C. politus* and *C. aszelianus*, inhabiting the Southern States; *C. nuttalli*, a large and beautiful insect of Missouri, first noticed by Mr. Nuttall, and said to surpass the Spanish fly in magnitude and splendor; and *C. albida*, another large species, found by Mr. Say near the Rocky Mountains. Of these, *C. nuttalli* (*Lytta nuttalli*, Say, *Am. Entomol.*, i. 9) bids fair, at some future period, to be an object of importance in the western section of this country. The head is of a deep greenish color, with a red spot in front; the thorax is of a golden green; the elytra red or golden purple and somewhat rugose on their outer surface, green and polished beneath; the feet black; the thighs blue or purplish. The exploring party under Colonel Long ascertained the vesicating powers of this insect. It was found in the plains of the Missouri, feeding on a scanty grass. In one spot it was so numerous as to be swept away by bushels, in order that a place might be cleared for encamping. There are also a number of beetles found in the United States which are plentiful enough to be capable of affording a commercial article, and which are so closely allied to the genus Cantharis as to render it probable that they possess blistering properties. For an account of the more important, see *Proc. A. P. A.*, 1876, p. 506.

Mylabris bifasciata and *M. lunata*, said to be common South African beetles used by the natives for producing vesication, have appeared in the London market. They yielded to J. Oldham Braithwaite from 1·09 to 1·02 per cent. of cantharides. *Meloë proscarabæus* and *M. majalis* have been occasionally substituted for cantharides in Europe, and *M. trianthemæ* is used in the upper provinces of Hindostan. Mr. J. O. Braithwaite found the *Mylabris bifasciata* of the Cape of Good Hope extremely rich in cantharidin, whilst its co-dweller, *M. lineata*, contained but little. (*P. J. Tr.*, xviii. 246.) *Hueckys sanguinea*, or "*Chinese cantharides*" of the London market, does not contain cantharidin. (J. Moss, *P. J. Tr.*, xvii. 845.) *Epicauta gorhami* is said to be used in Japan as a cantharidal beetle. (*Pharm. Zeit.*, March, 1891.)

property of the insect was not injured by the worm, which was supposed to devour only the inactive portion. But this has been proved to be a mistake. M. Farines, an apothecary of Perpignan, has satisfactorily shown that, though the hard parts left by these mites possess some vesicating power, and the powder produced by them still more, yet the sound flies are much stronger than either. Camphor, which has been recommended as a preservative, does not prevent the destructive agency of the worm.* It is stated by M. Farines that when the flies are destroyed by the vapor of pyroligneous acid, instead of common vinegar, they acquire an odor which contributes to their preservation. Cantharides will bear a very considerable heat without losing the brilliant color of their elytra; nor is this color extracted by water, alcohol, ether, or the oils; so that the powder might be deprived of all its active principle and yet retain the exterior characters unaltered. The wing-cases resist putrefaction for a long time, and the shining particles have been detected in the human stomach months after interment.

So early as 1778, Thouvenel attempted to analyze cantharides, and the attempt was repeated by Dr. Beaupoil in 1803; but no very interesting or valuable result was obtained till 1810, when Robiquet discovered in them a crystalline substance, which proved to be the vesicating principle of the insect and received the name of *cantharidin*. The constituents, according to Robiquet, are—1, a green oil, insoluble in water, soluble in alcohol, and inert as a vesicatory; 2, a black matter, soluble in water, insoluble in alcohol, and inert; 3, a yellow viscid matter, soluble in water and alcohol, and without vesicating powers; 4, cantharidin; 5, a fatty matter, insoluble in alcohol; 6, calcium and magnesium phosphates, acetic acid, and, in the fresh insect, a small quantity of uric acid. Orfila afterwards discovered a volatile principle, upon which the fetid odor of the fly depends. It is separable by distillation with water. Prof. Dragendorff has found a volatile principle which acts on the system in the same manner as cantharidin. When powdered flies are moistened with water and distilled, the part which passes over, at or below 100° C. (212° F.), contains this principle. (*Chem. News*, May 31, 1867.) That the green coloring matter is chlorophyll seems to be shown by the experiments of Pocklington, who (*P. J. Tr.*, [3] iii. p. 681) found that when cantharides was treated with alcohol, ether, and carbon disulphide, the solutions yielded absorption spectra agreeing with that of chlorophyll. Cantharidin exists in commercial cantharides to the extent of from 0·7 to 0·9 per cent. E. Dieterich prepares cantharidin by macerating 1000 parts of coarsely powdered cantharides in 1500 parts of acetic ether mixed with 20 parts of sulphuric acid; after adding 40 parts of barium carbonate to neutralize the excess of sulphuric acid, the mixture is exhausted with acetic ether in an extraction apparatus, the liquid is distilled, and the residue, consisting of cantharidin, resin, fat, etc., is set aside for eight days to allow the cantharidin to crystallize; 200 parts of benzin (sp. gr. 0.740) are then added, gently heated in order to dissolve the fatty matter, the liquid filtered, and the cantharidin washed with benzin and recrystallized from its solution in 90 per cent. alcohol. If perfectly pure cantharidin is needed, the cantharidin may be dissolved in acetic ether and the solution passed through animal charcoal, filtered, and allowed to crystallize. (*Journ. de Pharm. et de Chim.*, 1893, 375.)

Cantharidin is a white substance, in the form of crystalline scales, of a shining micaceous appearance, inodorous, tasteless, almost insoluble in water and in cold alcohol, but soluble in ether, chloroform, benzol, the oils, and in hot alcohol and acetic acid, which deposit it upon cooling.† It fuses at 210° C. (410° F.), is volatilizable by heat without decomposition, and

* It appears from the experiments of M. Nivet that, though camphor does not preserve the entire fly from the attacks of the larvæ of the *Anthrenus*, it actually destroys the mites of the Cantharis so often found in the powder, and may, therefore, be introduced with advantage, in small lumps, into bottles containing powdered cantharides. (*Journ. de Pharm.*, xix. 604.) Ammonium carbonate has also been recommended as a preservative. Pereira has found that a few drops of strong acetic acid, added to the flies, are very effectual. Among the best means of preserving them, whether whole or in powder, is the application of the process of Apert, which consists in exposing them for half an hour, confined in glass bottles, to the heat of boiling water, which destroys the eggs of the insect, without impairing the virtues of the flies. (*Ibid.*, xxii. 246.) Of course the access of water to the flies should be carefully avoided. Lutrand recommends chloroform as the best preservative that he has tried. (*Journ. de Pharm.*, xviii. 214.) We have little doubt that exposure, in a confined vessel, to the vapor of carbolic acid, would be a perfect protection against all forms of insect life.

† *Cantharidin* (*solubility*). The solubilities of cantharidin were examined with great care by Professor Procter, with the following results. It is insoluble in water. Cold alcohol dissolves it slightly, hot alcohol freely. It is more soluble in ether, which also dissolves it more freely hot than cold. Chloroform, cold or hot, is its best solvent; and acetone ranks next to it in this respect. Olive oil, at 250° F., dissolves one-twentieth of its weight, and oil of turpentine, boiling hot, one-seventieth; and both deposit the greater portion on cooling. The olive oil solution after deposition vesicates, the terebinthinate does not. Strong acetic, sulphuric, and nitric acids dissolve it, with the aid of heat, and deposit it unchanged on cooling. It is also dissolved by solutions of potassa and soda, and to a small extent by a strong solution of ammonia. (*A. J. P.*, xxiv. 296.) Formic acid is said to be the best solvent. Somewhat different results in relation to the solubility of cantharidin have been obtained by M. E. Rowan. Careful ex-

its vapor condenses in acicular crystals. As determined by the experiments of Mr. Wm. A. Guy, the subliming heat of isolated cantharidin is 100° C. (212° F.), or the temperature of boiling water. (*P. J. Tr.*, Feb. 1868, 373.) According to MM. Masing and Dragendorff, cantharidin, with the composition $C_{10}H_{12}O_4$, is capable of combining with water, and thus becomes cantharidic acid, $C_{10}H_{14}O_5$, and in this state forms definite compounds with bases, such as $K_2C_{10}H_{12}O_5$ and $Na_2C_{10}H_{12}O_5$, which are crystallizable. These may be obtained by heating cantharidin with an alkaline solution. (*Journ. de Pharm. et de Chim.*, Janv. 1868, 79.) Cantharidin itself has been found to combine like an acid with the salifiable and earthy bases, forming soluble compounds with potassium, sodium, and lithium hydrates, salts of very sparing solubility with baryta, strontia, and lime, and with magnesia a salt which, though feebly soluble in water (100 parts of water dissolving only 0·24 of the salt) (see *P. J. Tr.*, March 13, 1880), is much more largely dissolved in cold than in hot water, and in cold than in hot alcohol. Cantharidin is therefore recognized as the lactone or inner anhydride of cantharidic acid. The potassium salt crystallizes with 3 molecules of water, and is soluble in 25 parts of water. On the addition of strong acids to this solution, cantharidic acid is not precipitated, as might be expected, but the lactone cantharidin. This potassium salt has been recommended by Liebreich for use in subcutaneous injections in cases of *phthisis*, but is of very doubtful value. The most satisfactory test of cantharidin is its vesicating property. Notwithstanding the insolubility of this principle in water and cold alcohol, the decoction and tincture of cantharides have the medicinal properties of the insect; and Lewis ascertained that both the aqueous and alcoholic extracts act as effectually in exciting vesication as do the flies themselves, while the residue is in each case inert. Cantharidin consequently exists in the insect so combined with the yellow matter as to be rendered soluble in water and cold alcohol. If, as stated by E. Dieterich (1883), formic acid is present in the Spanish fly, it is probable that the solution of the cantharidin is due to its presence. H. G. Greenish calls attention to the fact that much loss of cantharidin takes place in making the various pharmaceutical preparations, through insufficient exhaustion by the use of the ordinary solvents. He obtained 0·822 per cent. of cantharidin from exhausted residues. Homolka records in *Ber. d. Chem. Ges.*, xix. 1082, the results of an investigation of the chemical decompositions of cantharidin.

Adulterations. These are not common. Occasionally other insects, or even beads, are added, purposely, or through carelessness. These may be readily distinguished by their appearance. Flies exhausted of their cantharidin are sometimes substituted for the genuine drug. They are worthless, and are to be distinguished by their lack of substance and their yielding a nearly colorless ethereal tincture. Pereira states that powdered flies are sometimes adulterated with euphorbium. According to the researches of Mr. Fahnestock (*A. J. P.*, 1879, p. 298), age destroys the activity of the drug without of necessity impairing its physical appearance.

The percentage of cantharidin found in cantharides furnishes the best test of their virtues. Professor Procter succeeded, by means of chloroform, in isolating cantharidin with great facility. He treated the flies with chloroform by percolation, displacing the last portion by means of alcohol, and allowing the resulting solution to evaporate spontaneously. Cantharidin is thus obtained in crystals mixed with the green oil, the greater portion of which may be removed by bibulous paper. The residuary crystals are dissolved in a mixture of ether and alcohol, which, by the spontaneous evaporation of the ether, yields the cantharidin nearly pure. M. Mortreux, having ascertained that the cantharidin is insoluble in carbon disulphide, proposed to use this fluid for removing the fatty matter associated with the cantharidin crystals obtained by the use of chloroform. He employed the same liquid in estimating the proportion of cantharidin, which he found to be about 20 centigrammes for 40 grammes of the flies, or half of one per cent. (*Journ. de Pharm. et de Chim.*, 3e sér., xlvi. 33, 1864.) Wittstein obtains it by digesting coarsely-powdered flies repeatedly with water, straining through linen and expressing, allowing the liquid to settle for a day, separating the supernatant oil, adding a little wood charcoal, evaporating to dryness, treating the residue with ether so long as the solution affords a laminated substance on evaporation, evaporating the ethereal solution, treating the residue with cold alcohol of 80 per cent. for one day with frequent shaking, and finally drying the scales. (See *A. J. P.*, xxviii.) Mr. Williams has obtained it by means of benzol. (*Ibid.*, xxvi.) For a method of assaying cantharides and its official preparations by Prof. H. G. Greenish and Harold Wilson, see *P. J. Tr.*, 1898, 255, or *Amer. Drug.*, 1898, 224.

amination with distilled water showed that, when agitated for eight days at ordinary temperatures with pure cantharidin, it was capable of dissolving 0·0266 per cent. of that principle; boiling water dissolves 0·297 per cent.; boiling alcohol (99 Tralles) 2·168 per cent. (*Journ. de Pharm.*, Mai, 1873, 409.)

Medical Properties and Uses. Internally administered, cantharides is a powerful irritant, with a peculiar direction to the urinary and genital organs. Genito-urinary irritation is ordinarily the first symptom produced by small doses of cantharides, and, if the dose have been large enough, it may amount to violent strangury, attended with excruciating pain, and the discharge of bloody urine. Toxic doses of Spanish fly produce obstinate and painful priapism, vomiting, bloody stools, severe pains in the whole abdominal region, excessive salivation with a fetid cadaverous breath, hurried respiration, a hard and frequent pulse, burning thirst, exceeding difficulty of deglutition, sometimes a dread of liquids, frightful convulsions, tetanus, delirium, and death. Orfila has known twenty-four grains of the powder to prove fatal. Dissection reveals inflammation and ulceration of the mucous coat of the whole intestinal canal. According to M. Poumet, if the intestines be inflated, dried, cut into pieces, and examined in the sun between two pieces of glass, they will exhibit small shining yellow or green points, strongly contrasting with the matter around them. (*Journ. de Pharm.*, 3e sér., iii. 167.)* The poisonous effects are to be counteracted by emetics, cathartics, and opiates by the stomach and rectum. From the experiments of Schroff it seems that oils somewhat accelerate the poisonous action, probably by dissolving the cantharidin. (See *A. J. P.*, xxviii. 365.) By experiments upon dogs, M. Thouery, a French apothecary, has satisfied himself that animal charcoal possesses a real antidotal power. (*Journ. de Pharm.*, 1858, p. 65.) Cantharides have been long and beneficially used in medicine. Either these or other vesicating insects appear to have been given by Hippocrates in *dropsy* and *amenorrhœa*, in the latter of which complaints, when properly prescribed, they are a highly valuable remedy. They are also useful in obstinate *gleet*, *leucorrhœa*, and *seminal weakness*, and in *paralytic incontinence of urine*. They are used also in certain cutaneous eruptions, especially those of a scaly character, and in chronic *eczema*. Their unpleasant effects upon the urinary passages are best obviated by the free use of diluent drinks, and, when not consequent upon great abuse of the medicine, may almost always be relieved by an anodyne injection, composed of laudanum with a small quantity of mucilaginous fluid. The dose of Spanish flies is one or two grains (0·065–0·13 Gm.) of the powder, which may be given twice a day, in the form of pill. The tincture, however, is more frequently employed.

Externally applied, cantharides excites inflammation in the skin, which terminates in a copious secretion of serum under the cuticle. It may be employed either as a rubefacient, or to blister. In the former capacity it is seldom used, but as an epispastic it is preferred to all other substances. When blisters are allowed to stay on only long enough to irritate the skin, but not to blister, they are known as *flying blisters*. Used in this way, they are sometimes of service in *neuralgias*, applied directly over the seat of pain. Their chief value is, however, found in cases of severe internal irritation. It is of great importance that the practitioner clearly comprehend the distinct uses of the rubefacient and the blister. The rubefacient is to be employed as a revulsive when the internal irritation is severe but is not connected with pronounced organic change. The immediate impression of a rubefacient, acting as it does upon a much larger surface than does the blister, is greater than that of the blister, but the permanent revulsive action is much less. The blister is, therefore, to be used when the internal disease is connected with inflammatory structural change. Thus, in a case of *gastrodynia*, a rubefacient is of much more service than a blister, whilst the blister is decidedly more effective in *peritonitis*. In a general wide-spread *congestion of the lung* the rubefacient is to be preferred to the blister, but in *pneumonia* the blister to the rubefacient. As, however, congestion of neighboring parts usually accompanies a localized inflammation, a rubefacient is sometimes to be employed as a temporary substitute for or adjuvant to a blister. The amount of serous discharge produced by blisters appears to be sometimes of service in almost directly evacuating local serous exudations. Thus, not rarely, repeated blistering affords the best treatment of a *serous pleurisy*. Possibly, however, even in these cases, the blister acts purely as a counter-irritant, as it certainly does in *chronic rheumatism* and other *diseases of the joints*. In all *chronic joint inflammations* the best results may often be obtained by a reblistering, extending, if necessary, over weeks and months. In some cases of *skin disease* blisters are capable of substituting their own action for the original morbid disease, and they are still occasionally used for this purpose in *tinea capitis*, obstinate *herpes*, and other affections. The length of time that a blister should be applied varies with the individual and with the position of the disease. In

* Cantharidin may be detected in the body after death from poisoning. M. Dragendorff states that he has succeeded in finding it in the dead body of a cat three months after it had been taken, and is convinced that it might be discovered in the human corpse six months after burial. (*Journ. de Pharm.*, 1873, p. 443.)

some constitutions they produce a poisonous impression, attended with frequent pulse, dryness of the mouth, subsultus tendinum, and even convulsion. Such symptoms are probably the results of an intense peripheral nervous irritation acting upon very susceptible centres. Such is not, however, the case with the strangury which may follow absorption of the cantharidin, and which is always the result of the direct action of the cantharidin upon the genito-urinary tract. In order to avoid such genito-urinary irritation, and also as much as possible the pain at the seat of application, the blister should be left on only until it distinctly reddens the skin, when a flaxseed poultice may be applied, and in the course of two or three hours the blister is formed. The time necessary for such reddening of the skin is usually from four to six hours, if the cantharidin be active. (See *Ceratum Cantharidis.*)

Prof. Liebreich strongly recommends hypodermic injections of cantharidin in the treatment of *phthisis*, but general clinical experience has not confirmed the value of the remedy. *Liebreich's cantharidal solution* was made by heating 20 C.c. of water with 2 decigrammes of cantharidin and 4 of potassium hydrate until solution was obtained, then adding enough water to make one thousand cubic centimeters. The dose of the cantharidate was 0·0001 increased to 0·0002 Gm., or even beyond.

CAPSICUM. U. S. (Br.) Capsicum. [Cayenne Pepper. African Pepper.]

(CĂP'SĮ-CŬM.)

"The fruit of Capsicum fastigiatum, Blume (nat. ord. Solanaceæ)." *U. S.* "The dried ripe fruit of Capsicum minimum, Roxb." *Br.*

Gen. Ch. Corolla wheel-shaped. *Berry* without juice. *Willd.*

Owing probably to its wide-spread cultivation, the genus Capsicum contains a large number of plant forms whose specific relations afford a very difficult problem to the systematic botanist. The probability is that the entire genus was originally confined to the American tropics, although it has been cultivated since the time of Columbus in the temperate and tropical zones of almost the whole world. Its first appearance in literature seems to be in an epistle by Peter Martyn, dated September, 1493, speaking of its having been brought by Columbus. Neither in ancient Sanscrit, or Chinese, or Greek, or Latin, or Hebrew is there a name for it. In 1887 Prof. Asa Gray expressed his belief that there are only two species in the genus, although in the last previous revision of the genus, in 1852, Dunal had recorded fifty species. After a very wide-spread and careful study of the subject, including the cultivation of every procurable variety and species for four years in the Missouri Botanical Garden, H. C. Irish has reached the conclusion that the dictum of Gray was correct, and that there are really only two species of the genus: one which is herbaceous and annual or biennial, one which is shrubby and perennial.

The first of these is the one most extensively cultivated in Europe and in this country; it is the *C. annuum*, L. The second is in its varieties very largely grown in the tropical and subtropical latitudes, its fruit not ripening at all or only to a slight degree in the temperate zone. It is the species which was described under the name of *C. frutescens*, by Linnæus, in 1737. By Irish it is divided into two varieties,—*C. frutescens* proper, which is characterized by its fruit being oblong, acuminate, and usually embraced by the calyx, and *C. frutescens baccatum*, which is characterized by its ovate or subround fruit, usually seated on the calyx. This variety is the *C. baccatum* of Linnæus, 1767. In the first of these varieties are comprised the *C. fastigiatum* (Blume) and the *C. minimum* of Miller, which yield most of the Cayenne pepper produced in the tropics, although, especially in the West Indies and South America, *C. baccatum* is largely cultivated. It is even doubtful whether *C. annuum* should be considered as a distinct species from *C. frutescens*, as in tropical climates varieties have been produced which are perennial and somewhat woody.

The British Pharmacopœia seems to be in error in ascribing the original description of the *Capsicum minimum* to Roxbury, since his *Flora Indica* did not appear until 1832, whereas the species was described by Miller, in the *Garden Dictionary*, in 1771.

Capsicum annuum. Willd. *Sp. Plant.* i. 1052; *B. & T.* 189. The stem of the annual capsicum is thick, roundish, smooth, and branching; rises two or three feet in height; and supports ovate, pointed, smooth, entire leaves, which are placed without regular order on long footstalks. The flowers are solitary, white, and stand on long peduncles at the axils of the leaves. The

calyx is persistent, tubular, and five-cleft; the corolla, monopetalous and wheel-shaped, with the limb divided into five spreading, pointed, and plaited segments; the filaments, short, tapering, and furnished with oblong anthers; the germen, ovate, supporting a slender style which is longer than the filaments and terminates in a blunt stigma. The fruit is a pendulous, pod-like berry, of varying shape and size, light, smooth, and shining, of a bright scarlet, orange, or sometimes yellow color, with two or three cells, containing a dry, loose pulp, and numerous flat, kidney-shaped, whitish seeds.

The following are the characteristics of the two varieties of the shrubby or perennial capsicum, as given by Irish:

C. frutescens, Linn. "Plants shrubby, perennial, two and a half to six feet high. Branches angular, often channelled, puberulent or pubescent, especially on the younger portions; usually greatly enlarged at the nodes, green or sometimes purplish striate, slightly purple at the nodes. Leaves broadly ovate, acuminate, three to six inches long, two or three and one-half inches wide, usually puffed or wrinkled, more or less pubescent, especially around the veins. Petioles medium, usually subciliate; peduncles slender, one to two inches long, often in pairs, usually longer than the fruit. Calyx usually cup-shaped, embracing base of the fruit; teeth short, corolla white or greenish white, spreading three-eighths to three-quarters inch, often with ocherous markings in the throat. Fruit red, ovate, obtuse or oblong acuminate, three-quarters to one and one-quarter inches long, one-quarter to three-quarters inch diameter."

C. frutescens baccatum, Linn. "Plants one to three feet high, under cultivation often six feet. Branches numerous, slender, fastigiate flexuose, usually quite densely purple, striate, scabrous, pubescent. Leaves ovate, acuminate, rather abruptly narrowing into the petioles, solitary or in twos, more or less pubescent along the veins and sometimes on the surface. Petioles short, usually hairy, broadened at base. Peduncles solitary or in twos, extreme axillary vertical (giving a peculiar character to the fruit), slender. One to one and one-quarter inches long, smooth, or on young specimens subhairy. Calyx short, cyathiform, subhairy, subciliate. Corolla small, spreading about one-half inch, greenish white. Fruit ovate or subround, about one-quarter inch diameter. Unripe fruit sometimes changing from green to blackish spotted, finally ripening into a red or yellow."

C. annuum is chiefly grown in this country; its flowers appear in July and August, and the fruit ripens in October. The several varieties of it differ in the shape of the fruit. The most abundant is probably that with a large irregularly ovate berry, depressed at the extremity, which is much used in the green state for pickling. The variety most used in making Cayenne pepper is that with long, conical, generally pointed, recurved fruit, usually not thicker than the finger. Sometimes small, spherical, slightly compressed berries, not greatly exceeding a large cherry in size, are met with. The red or Cayenne pepper of commerce is obtained by grinding the pods of several so-called varieties of capsicum, and is of variable strength. A variety of capsicum, consisting of very small, conical, pointed, exceedingly pungent berries, less than an inch in length, is imported from Liberia. In England the fruit of *C. annuum* is frequently called *chillies*. The U. S. Pharm. describes the fruit of *C. fastigiatum* as follows: "Oblong-conical, from 10 to 20 Mm. long, supported by a flattish, cup-shaped, five-toothed calyx, with a red, shining, membranous, and translucent pericarp, enclosing two cells, and containing flat, reniform, yellowish seeds attached to a thick, central placenta. It has a peculiar odor, and an intensely hot taste." The Br. Pharm. gives the characteristics of the fruit of *C. minimum* as "Dull orange-red, oblong-conical, obtuse, two-celled fruits, from about one-half to three-quarters of an inch (twelve to twenty millimetres) in length and a quarter of an inch (six millimetres) in diameter; sometimes attached to a five-toothed inferior calyx, and a long, straight, slender peduncle. The pericarp is somewhat shrivelled, glabrous, translucent, and leathery, and contains from ten to twenty small flat seeds, either loose or attached to a thin reddish dissepiment."

Powdered capsicum is usually of a more or less bright red color, which fades upon exposure to light and ultimately disappears. The color of the Liberia or African pepper, in powder, is a light brownish yellow. The odor is peculiar and somewhat aromatic, stronger in the recent than in the dried fruit. The taste is bitterish, acrid, and burning, producing a fiery sensation in the mouth, which continues for a long time. The pungency appears to depend on a peculiar principle, which was obtained, though not in a perfectly isolated state, by Braconnot, and named *capsicin*. It is obtained as a thick yellowish-red liquid, but slightly soluble in water. When gently heated it becomes very fluid, and at a higher temperature is dissipated in fumes which are extremely irritating to the respiration. It is a mixed substance, consisting of resinous and

fatty matters. In 1876, Thresh isolated a well-defined active principle, *capsaicin*, from the extract, which he obtained by exhausting Cayenne pepper with petroleum. From the red liquor dilute caustic alkali removes capsaicin, which is to be precipitated in minute crystals by passing carbonic acid through the alkaline solution. The crystals may be purified by recrystallizing them from either alcohol, ether, benzin, glacial acetic acid, or hot carbon disulphide; in petroleum capsaicin is but sparingly soluble, yet dissolves abundantly on addition of fatty oil. The latter being present in the pericarp is the reason capsaicin can be extracted by the above process. The crystals of capsaicin are colorless, and answer to the formula $C_9H_{14}O_2$; they melt at 59° C. (138·2° F.), and begin to volatilize at 115° C. (239° F.), but decomposition can be avoided only with great care. The vapors of capsaicin are of the most dreadful acridity, and even the ordinary manipulation of that substance requires much precaution. Felletar (*Journ. de Pharm.*, Avril, 1870, p. 347) first obtained from capsicum fruits a volatile alkaloid, which resembles coniine in odor, but is distinguished by the different shape of its hydrochlorate crystals. H. Pabst (1892) made a thorough investigation of the fruit of *C. annuum*. He does not think that an alkaloid exists originally in the fruit, but believes that the alkaloidal reactions are due to a decomposition product. He finds, besides *capsaicin*, a red coloring matter, and oleic, palmitic, and stearic acids. The red coloring matter, by saponification, was shown to be a cholesterin ester of the fatty acids. (*A. J. P.*, 1892, 370.) Moerbitz (1898) isolated a pungent principle having a bitter taste, which he states is neither capsicin nor capsicol, and names *capsicutin*. Red lead oxide is sometimes added to the powdered capsicum sold in Europe. It may be detected by digesting in diluted nitric acid, and precipitating the lead by sodium sulphate. Capsicum is said to be sometimes adulterated with colored sawdust; to be recognized by the microscope. It is often adulterated with inert vegetable substances. The British Pharmacopœia requires that capsicum should yield on incineration not more than 6 per cent. of ash; this test would detect the presence of most adulterants. The cut represents the characteristic cells of ground capsicum. It is occasionally attacked by insects.

Fragments of tissue from powdered capsicum.

Medical Properties and Uses. Cayenne pepper is a powerful local stimulant, producing when swallowed a sense of heat in the stomach, and a general glow over the body without any narcotic effect. It is much employed as a condiment, and proves highly useful in correcting the flatulent tendency of certain vegetables and aiding their digestion. Hence the advantage derived from it by the natives of tropical climates, who live chiefly on vegetable food. In the East Indies it has been used from time immemorial. From a passage in the works of Pliny, it appears to have been known to the Romans. As a medicine it is useful in cases of enfee led and languid stomach, and is occasionally prescribed in *dyspepsia* and *atonic gout*, particularly when attended with much flatulence, or occurring in persons of intemperate habits. It has also been given as a stimulant in *palsy* and certain *lethargic affections*. To quinine sulphate it forms an excellent addition in some cases of *intermittents* in which there is a great want of gastric susceptibility. Upon the same principle of rousing the susceptibility of the stomach, it may prove useful in low forms of fever, as an adjuvant to tonic or stimulant medicines. Its most important application, however, is to the treatment of *malignant sore throat* and *scarlet fever*, in which it is used both internally and as a gargle. The following formula was employed in *malignant scarlatina*, with great advantage, in the West Indies, where this application of the remedy originated. Two tablespoonfuls (31·1 Gm.) of the powdered pepper, with a teaspoonful (3·9 Gm.) of common salt, are infused for an hour in a pint of boiling liquid composed of equal parts of water and vinegar. This is strained, when cool, through a fine linen cloth, and given in the dose of a tablespoonful (15 C.c.) every half-hour. The same preparation is also used as a gargle. It is, however, only to the worst cases that the remedy is applied so energetically. In milder cases of scarlatina, with inflamed or ulcerated throat, much relief and positive advantage often follow the employment of the pepper in a more diluted state. Capsicum has been advantageously used in *sea-sickness*, in the dose of a teaspoonful (3·9 Gm.), given in some convenient vehicle on the first occurrence of nausea. It is thought also to have been beneficial in *hemorrhoidal affections*. It has long been used as a stomachic stimulant in the *enfeebled digestion of drunkards*, and in *delirium tremens*.

Applied externally, Cayenne pepper is a powerful rubefacient, which has the advantage of acting speedily without endangering vesication. It may be applied in the form of cataplasm, or more conveniently and efficiently as a lotion, mixed with heated spirit. The powder or tincture brought into contact with a *relaxed uvula* often acts very beneficially. The tincture has also been used advantageously in *chilblain*. The fluid extract and the ethereal extract (*Oleoresina Capsici, U. S.*) are powerfully rubefacient.

The dose of the powder is from five to ten grains (0·33–0·65 Gm.), which is most conveniently given in the form of pill. Of an infusion prepared by adding two drachms to half a pint of boiling water, the dose is half a fluidounce (15 C.c.). A gargle may be prepared by infusing half a drachm of the powder in a pint of boiling water, or by adding half a fluidounce of the tincture to eight fluidounces of rose-water.

CARBO. Carbon.

C; 11·97. (CÄR'BŌ.) **C; 12.**

Pure Charcoal; Carbone, *Fr.;* Carbonio, *It.;* Kohlenstoff, *G.;* Carbon, *Sp.*

Carbon is an element of great importance, and very extensively diffused in nature. It exists in large quantity in the mineral kingdom, and is the most abundant constituent of animal and vegetable matter. In the crystallized state it constitutes the diamond; and, more or less pure, it forms the substances called graphite, or black lead, plumbago, anthracite and bituminous coal, coke, animal charcoal, and vegetable charcoal. Combined with oxygen it forms *carbon dioxide*, or *carbonic acid gas*, which is a constituent of the atmosphere, and present in many natural waters, especially those which have an effervescing quality. United with oxygen and a base it forms the carbonates, among others *calcium carbonate*, which is one of the most abundant minerals. There are three allotropic conditions of carbon, represented respectively by the diamond, graphite, and charcoal.

The *diamond* is found principally in India, in Brazil, and in South Africa. Several diamonds have been found in the gold regions of Georgia and North Carolina. This gem is perfectly transparent, and the hardest and most brilliant substance in nature. Its sp. gr. is about 3·5. It is fixed and unalterable in the fire, provided air be excluded, but is combustible in air or oxygen, the product being the same as when charcoal is burned, namely, carbon dioxide. It has been made artificially at the temperature of the electric arc (2500° to 3000° C.) by Moissan.

Next to diamond, graphite or plumbago is the purest natural form of carbon. Graphite is the substance of which black-lead crucibles and pencils are made. It is found in greatest purity in the mine of Borrowdale, in England, and in Ceylon, from which latter place most of the graphite of commerce is now obtained, but it also occurs very pure in this country, and in extensive deposits at Ticonderoga, N.Y., at Stourbridge, Mass., and in Canada. In physical characters it is utterly different from the diamond; it crystallizes in hexagonal plates, is very soft and unctuous, of 2 to 2·5 sp. gr., and generally contains a little ash. It was formerly supposed to be a carbide of iron; but in very pure specimens it is nearly free from iron, which must, therefore, be deemed an accidental impurity. *Anthracite*, the purest variety of natural coal, occurs in different parts of the world, but particularly in the State of Pennsylvania. It contains from 90 to 95 per cent. of carbon, and several per cent. of ash. *Bituminous coal* is another variety, containing, besides the fixed or free carbon, some 10 to 15 per cent. of volatile hydrocarbons or gas-making material. When this is driven off by the process of charring, as in the manufacture of coal-gas, a kind of mineral charcoal, called *coke*, is obtained, very useful in the arts as a fuel. When peat is charred, it is converted into *peat charcoal*, which forms a cheap disinfectant and deodorizer, applicable to the purification of hospitals, dissecting-rooms, factories, privies, etc.

Carbon may be obtained in a state approaching to purity by several processes. One method is to expose lamp-black to a full red heat in a close vessel. It may also be obtained, in a very pure state, by passing the vapor of volatile oils through an ignited porcelain tube, whereby the hydrogen and oxygen of the oil will be dissipated, and the charcoal left in the tube. The purest lamp-black is now made from natural gas in western Pennsylvania and in Ohio. This lamp-black is miscible with water, does not color ether, and is free from oily matter.

Properties. Carbon, in its uncrystallized state, is an insoluble, infusible solid, generally of a black color, and without taste or smell. It burns when sufficiently heated, uniting with the oxygen of the air, and generating carbonic acid gas. Its sp. gr. in the solid state, apart from its pores when in mass, is 3·5; but with the air of the pores included, it is only 0·44.

It is a very unalterable and indestructible substance, and has great power in resisting and correcting putrefaction in other bodies. When properly prepared, it possesses the property of absorbing the coloring and odorous principles of most liquids. (See *Carbo Animalis.*) Its other physical properties differ according to its source and peculiar state of aggregation. As a chemical element it enjoys a very extensive range of combination. It forms two compounds with oxygen, *carbon dioxide* (carbonic acid gas) and *carbon monoxide* (carbonous oxide). With hydrogen it forms a number of compounds, called *hydrocarbons*, of which the most interesting, excluding hypothetical radicals, are light carburetted hydrogen or marsh-gas, olefiant gas, the light and concrete oils of wine, the hydrocarbons constituting petroleum, and the various essential oils. With nitrogen it constitutes cyanogen, the compound radical of hydrocyanic or prussic acid; and united in minute proportion with iron it forms steel.

CARBO ANIMALIS. U. S. Animal Charcoal.

(CÄR'BŌ ĂN-Ĭ-MĀ'LĬS.)

"Charcoal prepared from bone." *U. S.*

Bone Black, Ivory Black; Charbon animal, Noir d'Os, *Fr.;* Thierische Kohle, Knochenkohle, Beinschwarz, Thierkohle, *G.;* Carbone animale, *It.;* Carbon animal, *Sp.*

Animal charcoal was not retained in the British Pharmacopœia (1898).

The animal charcoal employed in pharmacy and the arts is usually obtained from bones, by subjecting them to a red heat in close vessels. The residue of the ignition is a black matter, which when reduced to powder forms *bone-black*, sometimes incorrectly called *ivory-black.* Ivory by carbonization will furnish a black which, on account of its fineness and intensely black color, is more esteemed than the ordinary bone-black; but it is much more expensive.

In manufacturing bone-black, the bones, first boiled in water to separate the fat, are subjected to destructive distillation in iron cylinders connected with vessels which receive the ammoniacal liquor, called *bone-spirit*, together with a dark tarry liquid (*bone-oil*), this being a secondary product of the operation. When the distillate ceases to come over, the residue is charred bone, or bone-black. Bone consists of animal matter with calcium phosphate and carbonate. In consequence of the decomposition of the animal matter involved in this destructive distillation, the nitrogen and hydrogen, united as ammonia, and a part of the charcoal, in the form of carbonic acid gas, distil over; while the remainder of the charcoal is left in the cylinder, intermingled with the calcareous salts. M. Deiss, of Paris, proposes carbon disulphide as a solvent for the fat of bones, as it furnishes a larger and better product of fat, and renders the bones fitter for producing a good bone-black. This form of animal charcoal necessarily contains calcium phosphate and carbonate.

Properties. "Dull black, granular fragments, or a dull black powder, odorless, nearly tasteless, and insoluble in water or alcohol. When ignited, it leaves a grayish or yellowish-white ash, amounting to about 85 per cent. of the original weight of the portion taken, which should have been previously dried at 120°–125° C. (248°–257° F.) to a constant weight. The ash should be soluble in hydrochloric acid, with the aid of heat, leaving not more than a trifling residue. If 1 Gm. of Animal Charcoal be boiled for several minutes with a mixture of 3 C.c. of potassium hydrate test-solution and 5 C.c. of water, the filtrate should be colorless or nearly so (evidence of *complete carbonization*)." *U. S.* It is, however, more dense and less combustible than vegetable charcoal; from which, moreover, it may be distinguished by burning a small portion of it on a red-hot iron, when it will leave a residuum imperfectly acted on by sulphuric acid; whereas the ashes from vegetable charcoal readily dissolve in this acid, forming a bitterish solution.

Animal charcoal by no means invariably possesses the decolorizing property, as this depends upon its peculiar state of aggregation. If a piece of pure animal matter is carbonized, it usually enters into fusion, and, from the gaseous matter which is extricated, becomes porous and cellular. The charcoal formed has generally a metallic lustre, and a color resembling that of black lead. It has, however, little or no decolorizing power, even though finely pulverized.

The decolorizing power of vegetable charcoal was first noticed by Lowitz, of St. Petersburg; and that of animal charcoal by Figuier, of Montpellier, in 1811. In 1822 the subject was ably investigated by Bussy, Payen, and Desfosses. The power is generally communicated to charcoal by igniting it in close vessels, but not always. The kind of charcoal, for example, obtained from substances which undergo fusion during carbonization scarcely possesses the property, even though it may be afterwards finely pulverized. The property in question is

possessed to a certain extent by wood charcoal,* but is developed in it in a much greater degree by burning it with some chemical substance, which may have the effect of reducing it to an extreme degree of fineness. The most powerful of all the charcoals for discharging colors are those obtained from certain animal matters, such as dried blood, hair, etc., by first carbonizing them in connection with potassium carbonate, and then washing the product with water. Charcoal thus prepared seems to be reduced to a state of extremely minute division, and is, therefore, very porous. The next most powerful decolorizing charcoal is *bone-black*, in which the separation of the carbonaceous particles is effected by the calcium phosphate present in the bone. Vegetable substances also may be made to yield a good charcoal for destroying color, provided, before carbonization, they be well comminuted, and mixed with pumice stone, chalk, flint, or other similar substance in a pulverized state.

In the manufacture of yellow prussiate of potash there is obtained a fine black sediment, which has a powerful decolorizing action; this is sometimes attributed to the organic nitrogenous character of the material from which it is made.

The following table, abridged from one drawn up by Bussy, denotes the relative decolorizing power of different charcoals:

KINDS OF CHARCOAL.	Decolorizing power on Syrup.	Decolorizing power on Indigo.
Bone-black	1	1
Bone charcoal treated with an acid	1·6	1·8
Lamp-black, not ignited	3·3	4
Charcoal, from potassium acetate	4·4	5·6
Blood ignited with calcium phosphate	10	12
Lamp-black ignited with potassium carbonate	10·6	12·2
Blood ignited with chalk	11	18
White of egg ignited with potassium carbonate	15·5	34
Glue ignited with potassium carbonate	15·5	36
Bone charcoal, formed from bone deprived of calcium phosphate by an acid, and subsequently ignited with potassium carbonate	20	45
Blood ignited with potassium carbonate	20	50

In order to determine the commercial value of animal charcoal, M. Corenwinder has proposed to ascertain its power of absorbing lime from a solution of calcium saccharate of determinate strength. The value is in proportion to the absorbing power of the charcoal. A given weight of the charcoal to be tested is left in contact, for an hour, with a given volume of the solution of the saccharate, taken in excess. The liquid is then filtered, and a small measure of it saturated with dilute sulphuric acid of known strength. The less the acid necessary for this purpose, the greater the amount of lime absorbed, and the better the animal charcoal. (*Chem. Gaz.*, 1854; *Scientific American*, April 22, 1876; *Arch. d. Pharm.*, 1887; *Proc. A. P. A.*, 1887.)

Spent animal charcoal, which has been used by the sugar refiners, may have its decolorizing power restored by calcination, which destroys the organic matters that have become fixed in it; and it is stated that it may be submitted to this process twenty times before becoming unfit for use, although this depends upon the amount of calcium salts it takes up from the raw sugars, beet sugars using up the black faster than sugars from the cane. According to Pelouze, the same object may be accomplished by subjecting it to a weak solution of potassium or sodium carbonate. In removing the coloring matter, the alkaline solution becomes yellow. After its action the animal charcoal must be carefully washed, first with boiling water, and afterwards with acidulated water. But a process devised by MM. Leplay and Cuisinier is probably more effectual. The charcoal, without being removed from the cylinders, is thoroughly washed, treated by steam to remove viscous substances, and then percolated successively, 1, by a weak alkaline solution, which removes salts and some coloring matters; 2, by weak hydrochloric acid, which, in removing a certain amount of salts of lime, liberates coloring matter; 3, again with a weak alkaline solution, to carry off the remaining coloring matter; and 4, lastly by a solution of calcium biphosphate, by which the decolorizing power of the charcoal is restored.

* Dr. Stenhouse divides decolorizing charcoals into three classes. First, pure charcoals, which, being in a state of minute division, decolorize by their porosity alone. Second, those which, like aluminized charcoal and artificial bone-black, decolorize solely by the bases they contain, acting as mordants. Third, those which, like bone-black, decolorize partly by their mineral matter, and partly by their minutely-divided charcoal. (*P. J. Tr.*, Jan. 1857.)

Animal charcoal is capable of taking the bitter principles from infusions and tinctures, and iodine from liquids which contain it in solution. Its power, however, of acting on solutions and chemical compounds is much more decided in its purified state, as shown by both Warington and Weppen. (See *Carbo Animalis Purificatus;* see, also, *Ephemeris*, 1885, p. 721.)

Bone-black consists of about 90 per cent. of calcium phosphate and carbonate, and 10 per cent. of charcoal.

Pharm. Uses. Animal charcoal is used in pharmacy for decolorizing vegetable principles, such as gallic acid, quinine, morphine, veratrine, etc., and in the arts, principally for clarifying syrups in sugar refining, for depriving spirits distilled from grain of the penetrating impurity, called *fusel oil*, which imparts to them an unpleasant smell and taste, as first distilled, and for the filtration of petroleum residuums in the manufacture of petrolatum and petroleum jellies. (See *Petrolatum.*) The manner in which it is used as a decolorizer is to mix it with the substance to be decolorized, and to allow the mixture to stand for some time. The charcoal unites with the coloring matter, and the solution by filtration is obtained white and transparent. Its use, however, in decolorizing the organic alkalies and other vegetable principles no doubt causes a loss by absorption; since it has been shown by the experiments of M. Lebourdais, mentioned under the head of purified animal charcoal, that several of these principles may be obtained by the sole action of charcoal. For most pharmaceutical operations, and for use as an antidote, animal charcoal must be purified by hydrochloric acid from calcium phosphate and carbonate. (See *Carbo Animalis Purificatus.*) Voilé uses animal charcoal as an absorbent in a pill excipient for making creosote and croton oil pills. According to Guthe, a German chemist, bone charcoal, without purification, is to be preferred as a decolorizer in all cases in which the calcareous salts exert no injurious effect.

CARBO ANIMALIS PURIFICATUS. U. S. Purified Animal Charcoal.

(CÄR'BŌ ĂN-Ị-MĂ'LĬS PŪ-RĮ-FĮ-CĀ'TŬS.)

Charbon animal purifié, *Fr.;* **Gereinigte Knochenkohle,** *G.*

"Animal Charcoal, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Hydrochloric Acid, *three hundred grammes* [or 10 ounces av., 254 grains]; Boiling Water, *a sufficient quantity.* Introduce the Animal Charcoal into a capacious flask, add *two hundred grammes* [or 7 ounces av., 24 grains] of Hydrochloric Acid, and *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Boiling Water, and connect the flask with an upright condenser. By means of a sand-bath keep the mixture gently boiling during eight hours. Then add *five hundred cubic centimeters* [or 17½ fluidounces] of Boiling Water, transfer the mixture to a muslin strainer, and, when the liquid has run off, return the Charcoal to the flask. Add to it *one hundred grammes* [or 3 ounces av., 231 grains]* of Hydrochloric Acid and *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Boiling Water, boil for two hours, again add *five hundred cubic centimeters* [or 17½ fluidounces] of Boiling Water, transfer the whole to a plain filter, and, when the liquid has run off, wash the residue with Boiling Water until the washings give only a faint cloudiness with silver nitrate test-solution. Dry the powder in a drying oven, and immediately transfer it to well-stoppered vials." *U. S.*

"Take of Bone Black, in powder, *sixteen ounces* [avoirdupois]; Hydrochloric Acid *ten fluidounces;* Distilled Water *a sufficiency.* Mix the Hydrochloric Acid with a pint of the Water, and add the Bone Black, stirring occasionally. Digest at a moderate temperature for two days, agitating from time to time; collect the undissolved charcoal on a calico filter, and wash with Distilled Water until what passes through gives scarcely any precipitate with nitrate of silver. Dry the charcoal, and then heat it to redness in a closely-covered crucible." *Br.* 1885.

Animal charcoal, as it is made by charring bones, necessarily contains bone-phosphate and calcium carbonate, the presence of which does no harm in some decolorizing operations; but in delicate chemical processes these salts may be dissolved or decomposed, and thus become a source of impurity. It is on this account that animal charcoal requires to be purified from its calcareous salts; and this is accomplished by diluted hydrochloric acid, which dissolves the phosphate and decomposes the carbonate. According to Dr. Stenhouse, aluminized vegetable charcoal is equally efficacious with purified animal charcoal as a decolorizer. (See page 331.)

Properties. Purified animal charcoal is "a dull black powder, odorless, tasteless, and insoluble in water, alcohol, or other solvents. If 2 Gm. of the powder be ignited at a red heat

* The U. S. Pharmacopœia 1890 (1st edition) is evidently in error in stating this quantity as 100 cubic centi meters; it should be 100 grammes, to correspond with the quantity previously given.

with free access of air in a broad, shallow porcelain or platinum dish, it should not leave a residue weighing more than 0·08 Gm., or 4 per cent. of the original weight (limit of *silicates* and *other fixed, inorganic matter*). If 1 Gm. of the powder be boiled with a mixture of 3 C.c. of potassium hydrate test-solution and 5 C.c. of water during three minutes, the filtrate should be colorless (evidence of *complete carbonization*)." *U. S.*

It has been shown by Mr. Robert Warington that bitter vegetable substances, including the organic alkalies, are removed from solution by passing through purified animal charcoal, especially when the action is assisted by heat. M. Weppen finds that a similar effect is produced by it in removing resins from tinctures, tannic acid and bitter principles from astringent and bitter infusions, and certain metallic salts from their solutions. Purified animal charcoal, thus employed, has been resorted to by M. Lebourdais as an agent for obtaining the active principles of plants. A decoction or infusion of the plant is either boiled with or filtered through the charcoal, which takes up, more or less completely, the bitter and coloring principles. The charcoal, after having been washed and dried, is treated with boiling alcohol, which dissolves the principles taken up. Finally, the alcohol is distilled off, and the principles are obtained in a separate state. In this way digitalin, ilicin, scillitin, columbin, colocynthin, arnicine, strychnine, quinine, and other principles have been obtained by M. Lebourdais. (*Chem. Gaz.*, Nov. 15, 1848.) In relation to the method of M. Lebourdais, see a paper by Mr. J. S. Cobb, in *A. J. P.*, 1851. Dr. A. B. Garrod has proposed purified animal charcoal as an antidote to vegetable and animal poisons, with which it appears to combine. According to his experiments, common bone-black has not one-fifth of the power possessed by the purified substance, and vegetable charcoal and lamp-black are nearly or quite useless. The amount of the antidote proposed by Dr. Garrod is half an ounce for each grain of a vegetable organic alkali. Dr. Alfred Taylor deems the results of Dr. Garrod inconclusive. The late Professor B. H. Rand made some interesting observations in relation to the antidotal powers of purified animal charcoal, and proved that poisonous doses of the strongest vegetable poisons may be swallowed with impunity, if mixed with that substance. (*Med. Exam.*, Sept. 1848.) As an antidote for phosphorus (see *N. Y. Med. Record*, 1874, p. 68) its value is very doubtful.

In using animal charcoal for decolorizing active vegetable principles much loss is often incurred by the absorption of those principles by the charcoal.

CARBO LIGNI. U. S., Br. Charcoal.

(CÄR'BŌ LĬG'NĪ.)

"Charcoal prepared from soft wood, and very finely powdered. It should be kept in well-closed vessels." *U. S.* "The carbonaceous residue of wood charred by exposure to a red heat without access of air." *Br.*

Wood Charcoal, Vegetable Charcoal; Carbo Ligni Pulveratus, *P. G.;* Carbo Præparatus, Carbo e Ligno; Charbon végétal, Charbon de Bois, *Fr.;* Holzkohle, Präparirte Kohle, *G.;* Carbone di Legno, *It.;* Carbon de Lena, *Sp.*

Preparation on the Large Scale. Billets of wood are piled in a conical form, and covered with earth and sod to prevent the free access of air; several holes being left at the bottom and one at the top of the pile, in order to produce a draught to commence the combustion. The wood is then kindled from the bottom. In a little while the hole at the top is closed, and, after the ignition is found to have pervaded the whole pile, those at the bottom are stopped also. The combustion taking place with a smothered flame, the volatile portions of the wood, consisting of hydrogen and oxygen, are dissipated, while the carbon is left; a portion of it, however, being lost by combustion. Wood, thus carbonized, yields not more than 17 or 18 per cent. of charcoal. A better method is to char the wood in iron cylinders, when it yields from 22 to 23 parts in 100 of excellent charcoal; and, at the same time, the means are afforded for collecting the volatile products, consisting of pyroligneous acid, empyreumatic oil, and tar. This process for obtaining charcoal has been described under another head. (See *Acidum Aceticum.*) A method of preparing charcoal by subjecting wood to overheated steam has been invented by M. Violette. When the temperature of steam is 300° C. (572° F.), the wood is converted into a peculiar charcoal, called *red charcoal*, which is intermediate in its qualities between wood and ordinary charcoal. When the temperature is lower, the carbonization is incomplete; when higher, the product is black charcoal. The steam process yields a uniform charcoal for a given temperature, which may be easily regulated, and a product about double that obtained in closed cylinders. Charcoal contains *carbon*, approximately in proportion to the temperature at which it is formed; varying from 65 per cent. when made at 250° C. (482° F.) to 80 per cent. when made at 400° C. (752° F.). The gaseous matter

present, on the other hand, decreases with the temperature of carbonization. Thus, for charcoal made at 300° C. (572° F.), it is one-third of its weight; at 350° C. (662° F.), one-fourth.

Mr. E. C. C. Stanford has called attention to a variety of vegetable charcoal, obtained by charring a species of sea-weed, *Laminaria digitata*, gathered on the shores of the Hebrides, which, although, on account of the large proportion of calcium carbonate contained in it (20 per cent.), unfit for use in refining sugar, possesses more of the deodorizing and decolorizing power than animal charcoal itself, which, with the exception referred to, it closely resembles in chemical composition. (*P. J. Tr.*, 1867, 186.)

Preparation for Medicinal Use. M. Belloc recommends charcoal for this purpose to be obtained from poplar shoots, cut at the time the sap rises, and deprived of their bark. The carbonization should be performed in cast-iron vessels at a red-white heat. The product is a light and brilliant charcoal, which must be purified by being macerated for three or four days in water, frequently renewed. It is then dried, powdered, and placed in bottles, which should be well stopped. The charcoal most esteemed in Philadelphia for medicinal purposes is that prepared by the Messrs. Dupont, near Wilmington, Delaware, for the manufacture of gunpowder. It is made from young willow shoots of two or three years' growth.

Properties. Charcoal is a black, shining, brittle, porous substance, tasteless and inodorous, and insoluble in water. It is a good conductor of electricity, but a bad one of heat. It possesses the remarkable property of absorbing many times its own bulk of certain gases. "If 1 Gm. of Charcoal be boiled with a mixture of 3 C.c. of potassium hydrate test-solution and 5 C.c. of water for several minutes, the filtrate should be colorless or nearly so (evidence of *complete carbonization*)." *U. S.* The British Pharmacopœia describes it as "A black powder without taste or odor, free from gritty matter. When burned at a high temperature with free access of air, it should not leave more than 7½ per cent. of ash." When exposed to the air after ignition, charcoal increases rapidly in weight, absorbing from 12 to 14 per cent. of moisture. As ordinarily prepared, it contains the incombustible part of the wood, amounting to 1 or 2 per cent., which is left as ashes when the charcoal is burned. This inorganic material may be removed by digesting the charcoal in diluted hydrochloric acid, and afterwards washing it thoroughly with boiling water.

Medical Properties, etc. Powdered charcoal is disinfectant and absorbent. It is employed with advantage in *diarrhœa* as an absorbent, and in *dyspepsia* with fetid breath and eructations. It is also useful, in the form of injection, in *putrid discharges from the uterus.* M. Belloc recommends it strongly in *gastralgia*, and especially *pyrosis*, in which, if it fails to remove the disease, it abates the pain, nausea, and vomiting; and his observations have been confirmed by a committee of the French Academy of Medicine. As a remedy in *obstinate constipation*, Dr. Daniel, of Savannah, speaks of it in high terms. He also found it useful in *nausea and constipation of pregnancy.* On the other hand, some practitioners have found charcoal to confine the bowels. Dr. Wilson, of New Zealand, speaks highly of it in the *diarrhœa* of measles, and in epidemic cholera. Dr. Newman recommends it as a dressing to *wounds* and *ulcers.* Mr. Wormald, of St. Bartholomew's Hospital, has made a useful application of the disinfecting power of dry charcoal, in what he calls the *charcoal quilt.* This consists of two sheets of cotton wadding, quilted together in small segments, with a tolerably thick layer of powdered charcoal between them. The quilts, thus prepared, may be of any size, so as to fit a *gangrenous sore* or *stump.* Its use as an ingredient of poultices is noticed under *Cataplasma Carbonis.* Several of its varieties are used as tooth-powder. Those generally preferred are the charcoals of the cocoa-nut shell and of bread. It is said that charcoal proves useful in preserving the teeth by absorbing the acid sometimes morbidly present in the mucus of the mouth. The dose of charcoal varies from one to four teaspoonfuls (3·9–15·5 Gm.) or more. Dr. Daniel gave it in his case of constipation in doses of a tablespoonful (15·5 Gm.), repeated every half-hour. *Charcoal biscuits* have been prepared, containing 15 or 20 per cent. of charcoal in fine powder, whilst *charcoal lozenges*, either with charcoal alone or associated with bismuth, have been employed with asserted good results in certain forms of gastric disturbances.

For internal use charcoal is preferred by some in the *granular form.* Mr. W. Lascelles Scott employs the following method of preparing it. He prefers the wood of the box, willow, or linden, which, after being charred, should be allowed to cool out of contact with air, then boiled for some time in diluted hydrochloric acid, and afterwards, having been thoroughly washed with pure water, in a little weak ammonia. The fragments are again ignited, and then quickly powdered, and passed through a sieve of 80 or 100 apertures to the inch. Nine pounds

of this powder are mixed with one pound of pure sugar passed through a 30 sieve, and 4 ounces of gum arabic in impalpable powder. The whole is then moistened with a few ounces of warm distilled water, to which have been added an ounce and a quarter of tincture of benzoin, and a little mucilage. The mass is now granulated on flat steam pans, in the usual manner, at a temperature of 101·6°–107·2° C. (215°–225° F.). When perfectly dry it is sifted, and secured in well-stopped bottles. (*Chem. News*, 1867, p. 204.)

Dr. Stenhouse has devised a process for combining alumina with common vegetable charcoal, forming what he calls *aluminized charcoal*, which is an economical substitute for purified animal charcoal, and equally efficacious as a decolorizer. It is prepared by digesting finely-powdered charcoal with sufficient of the solution of aluminum sulphate to give an impregnation of 7·5 per cent. of alumina. The whole is evaporated to dryness, and ignited in a covered Hessian crucible, until the water and acid have been dissipated. Aluminized charcoal is perfectly black, though thoroughly impregnated with anhydrous alumina, and only requires to be carefully pulverized to be ready for use. (*P. J. Tr.*, 1857, p. 364.) On similar principles, Dr. Stenhouse prepares his *artificial bone-black*, by impregnating powdered wood charcoal with 7·5 per cent. of calcium phosphate, by digesting it in a solution of this salt in hydrochloric acid, evaporating to dryness, and igniting in covered vessels. This charcoal decolorizes well, but can be used only for neutral solutions.

Charcoal may act either as an oxidizer or as a deoxidizer, these contrary powers depending upon the temperature of the experiment; at the ordinary temperature, by its porosity, it facilitates atmospheric oxidation of animal matter with which it is placed in contact, while, on the other hand, at a low red heat it deoxidizes or reduces many metallic oxides with the formation of carbon monoxide. Thus, the bodies of two dogs having been laid in an open box on a bed of charcoal a few inches deep, and covered by the same material, were kept by Mr. John Turnbull, of Glasgow, for six months in his laboratory, without emitting any perceptible effluvium; and when they were examined at the end of this time, scarcely anything remained but the bones. Dr. Stenhouse, who relates this experiment, has confirmed it by observations of his own, and believes that the animal matter thus treated undergoes putrefaction, though the products, by their rapid oxidation and absorption, are prevented from contaminating the air. He therefore considers charcoal not to be antiseptic, but the very opposite. It is said that water may be kept sweet at sea by the addition of a little powdered charcoal to each cask.

CARBONEI DISULPHIDUM. U. S. (Br.) Carbon Disulphide.

[Carbonei Bisulphidum, Pharm. 1880.]

CS_2; 75·93. (CĂR-BŌ'NĒ-Ī DĪ-SŬL'PHĮ-DŬM.) CS_2; 76.

"Carbon Disulphide should be kept in well-stoppered bottles, or in tin cans, in a cool place, remote from lights or fire." *U. S.* "Carbon Bisulphide, CS_2, may be prepared by the combination of carbon and sulphur at a high temperature, the product being subsequently condensed and purified." *Br.*

Carbonis Bisulphidum, *Br.*, Carbon Bisulphide; Carboneum Sulfuratum, Alcohol Sulfuris, *P. G.;* Carbonii Bisulphidum; Carbon Sulphide; Sulfure de Carbone, *Fr.;* Schwefelkohlenstoff, *G.*

This compound, corresponding to carbon dioxide (carbonic acid gas), CO_2, is prepared by the direct combination of carbon and sulphur at a moderate red heat. To effect this, charcoal is heated to redness in a vertical cylinder, while sulphur is admitted through a lateral tubulure near the bottom. As the sulphur melts and vaporizes, it combines with the carbon, and the carbon disulphide formed distils over through a series of condensing tubes, which, while they serve to collect the crude carbon disulphide, allow of the escape of the hydrogen sulphide formed at the same time. The crude product is then rectified, first over a solution of chlorinated lime to break up any hydrogen sulphide gas remaining, and then repeatedly either over mercury, mercuric chloride, anhydrous cupric sulphate, or over a pure fatty oil, which withdraws from it all free sulphur and bad-smelling sulphur compounds. Obach experimented with potassium permanganate as a purifying agent, as was suggested by Allary. He finds it well adapted for use on a small scale in combination with mercury, sulphur, mercuric sulphate. (*N. R.*, 1883.) The manufacture of carbon disulphide has within late years assumed large proportions. In the works of Deiss at Pantin, near Marseilles, France, 500 kilogrammes are turned out daily, and their annual production exceeds 1,200,000 kilogrammes.

It is used in the arts for the extraction of oils from different oil-seeds, for the extraction of sulphur from some varieties of sulphur ores, for the cleansing of wool and recovering the fat,

as a solvent for caoutchouc in the manufacture of india-rubber goods, for the extraction of perfumes, and latterly on an enormous scale in France as a remedy against the *phylloxera*. Von Lengyel describes a carbon sulphide having the composition C_3S_2. (*Proc. A. P. A.*, 1893, 1021.)

Properties. "A clear, colorless, highly refractive liquid, very diffusive, having a strong, characteristic, but not fetid odor, and a sharp, aromatic taste. Soluble in 535 parts of water at 15° C. (59° F.); very soluble in alcohol, ether, chloroform, fixed and volatile oils. Specific gravity, 1·268 to 1·269 at 15° C. (59° F.). Carbon Disulphide vaporizes rapidly at the ordinary temperature, is highly inflammable, boils at 46°–47° C. (114·8°–116·6° F.), and, when ignited, burns with a blue flame, producing carbon and sulphur dioxide. It should not affect the color of blue litmus paper moistened with water (absence of *sulphur dioxide*). A portion evaporated spontaneously in a glass vessel should leave no residue (absence of *dissolved sulphur*). Lead acetate test-solution agitated with it should not be blackened (absence of *hydrogen sulphide*)." *U. S.*

Medical Properties. Carbon disulphide is a powerful poison, but is not used as an internal remedy. According to M. Delpech, the workmen exposed to the fumes of the disulphide are affected with headache, vertigo, and over-excitement of the nervous system, as evinced by voluble talking, incoherent singing, or immoderate laughter, or sometimes by weeping; and a continuance of the exposure is apt to finally cause a state of cachexia, characterized by general weakness, loss of sexual appetite, dulness of sight and hearing, and impairment of memory. Later writers assert that these phenomena are hysterical, and that what the carbon disulphide does is to produce an hysterical neurosis. (See *Annales de Hygiène*, 1895, xxxiii.) The swallowing by a man of half an ounce of carbon disulphide was followed in half an hour by absolute unconsciousness, very rapid, feeble pulse, slow and stertorous respiration, cold and clammy surface of body, and insensitive conjunctiva, with mobile pupils. Two hours later, death occurred. The blood was found fluid, but there were no marked lesions of irritation in the gastro-intestinal mucous membrane. (*Lancet*, July 17, 1886.) India-rubber workers, by whom the disulphide is largely used, are said to suffer frequently from paralytic symptoms. (*Lancet*, Jan. 1886.)

Externally, the disulphide has been used as a counter-irritant and local anæsthetic. In *enlarged lymphatic glands*, Dr. Turnbull has employed it with asserted good success. He applies it by means of a bottle with a proper-sized mouth, containing a fluidrachm of the disulphide, imbibed by a piece of sponge. The skin over the gland is first well moistened with water. He employed the vapor also with benefit in deafness, when dependent on want of nervous energy and a deficiency of wax. For this purpose, the bottle containing the disulphide is made with a neck to fit the meatus, and, being applied to the ear, is held there until considerable warmth is produced. The remedy has been used often with very good results, in a similar manner, in *facial* and other *neuralgias* and various local *pains*. It causes a good deal of smarting, but its disagreeable odor is the chief objection to it. M. Chiandi Bey finds that a solution of carbon disulphide (three parts per thousand) is a most energetic antiseptic, killing microbes and arresting all fermentation; he proposes its use in *zymotic diseases* internally. (*Compt.-Rendus*, xcix.) In France the disulphide has been used in *diarrhœa* in 3·5 per cent. solution, of which the dose is two tablespoonfuls (30 C.c.) four or five times a day.

CARDAMOMUM. U. S. (Br.) Cardamom.

(CÄR-DA-MŌ'MŬM.)

"The fruit of Elettaria repens (Sonnerat), Baillon (nat. ord. Scitamineæ)." *U. S.* "The dried ripe seeds of Elettaria Cardamomum, Maton. The seeds should be kept in their pericarps and separated when required for use." *Br.*

Cardamomi Semina, *Br.;* Cardamoms; Fructus (Semen) Cardamomi Minoris, *P. G.;* Cardamomum Minus, Cardomomum Malabariam; Malabar Cardamoms; Cardamomes, Petit Cardamome, *Fr.;* Cardamomen, Kleine Cardamomen, *G.;* Cardamomo minore, *It.;* Cardamomo menor, *Sp.;* Ebil, *Arab.;* Kakelah seghar, *Pers.;* Capalaga, *Malay;* Gujaratii elachi, *Hindost.*

The subject of Cardamom has been involved in some confusion and uncertainty, both in its commercial and botanical relations. The name has been applied to the aromatic capsules of various Indian plants belonging to the family of Scitamineæ. Three varieties have long been designated by the several titles of the *lesser*, *middle*, and *larger*,—*cardamomum minus*, *medium*, and *majus;* but these terms have been used differently by different writers, so that their precise signification remains doubtful. To the late Dr. Pereira we are mainly indebted for the clearing

up of this confusion. It is well known that the *lesser cardamom* of most writers is the variety recognized by the Pharmacopœias and generally kept in the shops. The other varieties, though circulating to a greater or less extent in European and Indian commerce, are little known in this country.* The following remarks have reference exclusively to the genuine Malabar, or official, cardamom.

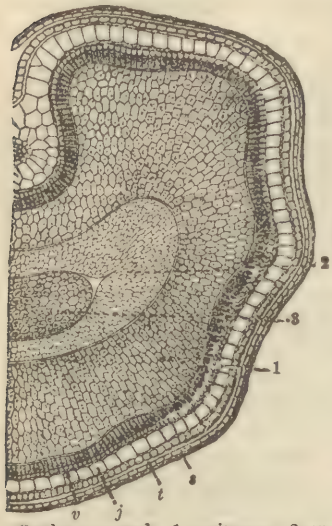
* 1. *Ceylon Cardamom.* This has been denominated variously *cardamomum medium*, *cardamomum majus*, and *cardamomum longum*, and is sometimes termed in English commerce *wild cardamom.* It is the *large cardamom* of Guibourt. In the East it is sometimes called *grains of Paradise:* but it is not the product known with us by that name. (See below.) It is derived from a plant cultivated in Candy, in the island of Ceylon, and also growing wild in the forests of the interior, which was designated by Sir James Edward Smith *Elletaria major*, but is now generally acknowledged to be only a variety of the official plant. This plant was described by Pereira in *P. J. Tr.* (ii. 388). The fruit is a lanceolate-oblong, acutely triangular capsule, somewhat curved, about an inch and a half long and four lines broad, with flat and ribbed sides, tough and coriaceous, brownish or yellow ash-colored, having frequently at one end the long, cylindrical, three-lobed calyx, and at the other the fruit-stalk. It is three-celled, and contains angular, rugged, yellowish-red seeds, of a peculiar fragrant odor and spicy taste. Its effects are analogous to those of the official cardamom.

2. *Round Cardamom.* This is probably the Ἄμωμον of Dioscorides and the *Amomi uva* of Pliny, and is believed to be the fruit of *Amomum cardamomum* (Willd.), growing in Sumatra, Java, and other East India islands. The capsules are usually smaller than a cherry, roundish or somewhat ovate, with three convex sides, more or less striated longitudinally, yellowish or brownish white, and sometimes reddish, with brown, angular, cuneiform, shrivelled seeds, which have a spicy camphorous flavor. They are sometimes, though rarely, met with connected in their native clusters, constituting the *amomum racemosum*, or *amome en grappes*, of the French. They are similar in medicinal properties to the official, but are seldom used except in the southern parts of Europe.

3. *Java Cardamom.* The plant producing this variety is supposed to be the *Amomum maximum* of Roxburgh, growing in Java and other Malay islands in the East. The capsules are oval, or oval-oblong, often somewhat ovate, from eight to fifteen lines long, and from four to eight broad, usually flattened on one side and convex on the other, sometimes curved, three-valved, and occasionally imperfectly three-lobed, of a dirty grayish-brown color, and coarse fibrous appearance. When soaked in water, they exhibit as their distinguishing character from nine to thirteen ragged membranous wings along their whole length, which distinguish them from all other varieties. The seeds have a feebly aromatic taste and smell. This variety of cardamom affords but a very small proportion of volatile oil, is altogether of inferior quality, and, when imported into London, is usually sent to the continent.

4. *Madagascar Cardamom.* This is the *Cardamomum majus* of Geiger and some others, and is thought to be the fruit of *Amomum angustifolium* of Sonnerat, growing in marshy grounds in Madagascar. The capsule is ovate, pointed, flattened on one side, striated, with a broad circular scar at the bottom, surrounded by an elevated, notched, corrugated margin. The seeds have an aromatic flavor analogous to that of official cardamom.

5. *Bengal Cardamom.* The fruit of *Amomum subulatum*, Roxb., sometimes known by the name of Winged Bengal Cardamom. *Morung elachi*, or *Buro elachi*, is about an inch in length, obscurely three-sided, ovoid or somewhat obconic, with nine narrow, jagged ridges or wings (best seen after soaking in water) upon its distal end, which terminates in a truncate bristly nipple. The pericarp is coarsely striated, of a deep brown, splitting into three valves, disclosing a three-lobed mass of seeds, 60 to 80 in number, agglutinated by their viscid saccharine anthers.



6. *Nepal Cardamom* is produced by an Amomum of undetermined species, and resembles the Bengal cardamom, except in having a long tubular calyx on its summit, and in being usually attached to a stalk.

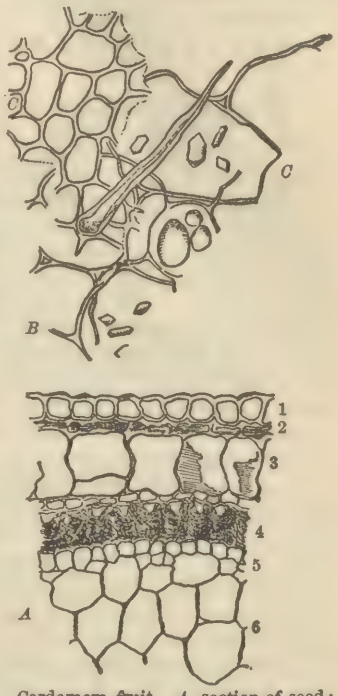
7. *Grains of Paradise. Grana Paradisi.* Under this name and that of *Guinea grains*, and *Malegueta* or *Mallaguetta pepper*, are found in commerce small seeds of a round or ovate form, often angular, and somewhat cuneiform, minutely rough, brown externally, white within, of a feebly aromatic odor when rubbed between the fingers, and of a strongly hot and peppery taste. Two kinds of them are known in the English market, one larger, plumper, and more warty, with a short conical projecting tuft of pale fibres on the umbilicus; the other smaller and smoother, and without the fibrous tuft. The latter are the most common. It is probable that one of the varieties is produced by *Amomum grana paradisi* of Sir J. E. Smith, and the other by Roscoe's *Amomum melegueta*. (Pereira's *Mat. Med.*, 3d ed., p. 1134.) Dr. W. F. Daniell, who has published (*P. J. Tr.*, xiv. 312 and 356) an elaborate paper on the Amoma of Western Africa, states that the true Mallaguetta pepper is obtained exclusively from varieties of the same species to which belong the *Amomum grana paradisi* of Afzelius and the *A. melegueta* of Roscoe; while the *A. grana paradisi* of Sir J. E. Smith is a different plant, and yields a different product. These grains are imported from Guinea, and other parts of the western coast of Africa. Similar grains are taken to England from Demerara, where they are obtained from a plant cultivated by the negroes, supposed to have been brought from Africa, and believed by Dr. Pereira to be the *Amomum melegueta* of Roscoe. (*Ibid.*, vi. 412.) At the international exhibition of 1862, at London, Dr. Geo. B. Wood noticed a specimen of similar grains, under the name of grains of Paradise, sent from the island of Trinidad. Their effects on the system are analogous to those of pepper; but they are seldom used except in veterinary practice, and to give artificial strength to spirits, wine, beer, and vinegar. In the same journal (ii. 443), Dr. Pereira points out seven distinct scitamineous fruits to which the name of grains of Paradise has been applied by different authors. J. C. Thresh made a proximate analysis of the seeds, and found volatile oil, resin, tannin, starch, albuminoids, and an active principle in the form of a straw-colored, viscid, odorless fluid, pungent, but not so hot as capsaicin. (*P. J. Tr.*, 1884, p. 297.) Fredk. Schwartz found in the seeds a reddish-brown acrid resin, and an oil having a burning aromatic taste, upon which the virtues probably depend. (*A. J. P.*, 1886, 118; consult also Hanausek's researches on grains of Paradise in *Chem. Zeit.*, 1893, 1765.)

Bastard Cardamom, the seeds of *Amomum Xanthoides*, resembles true cardamomum in appearance, but is of a dirty green color, and has a very biting camphor-like taste. Dr. B. Niederstadt gives the following as the results of analysis of the true (hulled) seed and of the bastard cardamom:

	True.	Bastard.
Water	15·25	15·50
Ether soluble extract	5·10	4·04
Ash	6·55	7·50
Starch and sugar	28·84	24·00
Cellular tissue, nitrogenous matters and extractive	44·26	48·96

Linnæus confounded, under the name of *Amomum cardamomum*, two different vegetables, —the genuine plant of Malabar, and another growing in Java. These were separated by Willdenow, who conferred on the former Sonnerat's title of *Amomum repens*, while he retained the original name for the latter, though not the true cardamom plant. In the tenth volume of the Linnæan Transactions, 1811, Mr. White, a British army surgeon in India, published a very minute description of the Malabar plant, which he had enjoyed frequent opportunities of examining in its native state. From this description Dr. Maton inferred that the plant, according to Roscoe's arrangement of the Scitamineæ, could not be considered an *Amomum;* and, as he was unable to attach it to any other known genus, he proposed to construct a new one, with the name of *Elettaria*, derived from *elettari* or *elatari*, the Malabar name of this vegetable. Sir James Smith afterwards suggested the propriety of naming the new genus *Matonia*, in honor of Dr. Maton; and the latter title, having been adopted by Roscoe, obtained a place in former editions of the London and U. S. Pharmacopœias. The celebrated Dr. Roxburgh described the Malabar cardamom plant as an *Alpinia*, with the specific name *cardamomum*. As doubts were entertained of the necessity for the new genus proposed by Maton, Roxburgh was followed in the London and U. S. Pharmacopœias, and the fruit was referred to *Alpinia cardamomum*. This decision, however, was revised in the later editions of the U. S. and British Pharmacopœias. Roscoe arranged it with the abandoned genus *Renealmia* of Linnæus, which he restored.

Cardamom seed. 1, perisperm; 2, endosperm; 3, embryo; *v*, inner seed-coat; *j*, oil cells; *s*, seed-coat; *t*, outer seed-coat. (After Berg.)



Gen. Ch. Corolla with the tube filiform and the inner limb one-lipped. *Anther* naked. *Capsule* often berried, three-celled, three-valved. *Seeds* numerous, arillate. *Blume.*

Elettaria cardamomum. Maton; *B. & T.* 267.—*Alpinia cardamomum.* Roxburgh.—*Amomum repens.* Sonnerat; Willd. *Sp. Plant.* i. 9.—*Renealmia cardamomum.* Roscoe, *Monandrous Plants.* Figured in *Linn. Trans.* x. 248, and Carson's *Illust. of Med. Bot.* ii. 55. The cardamom plant has a tuberous horizontal root or rhizome, furnished with numerous fibres, and sending up from eight to twenty erect, simple, smooth, green and shining, perennial stems, which rise from six to twelve feet in height, and bear alternate sheathing leaves. These are from nine inches to two feet long, from one to five inches broad, elliptical-lanceolate, pointed, entire, smooth and dark green on the upper surface, glossy and pale sea-green beneath, with strong midribs, and short footstalks. The flower-stalk proceeds from the base of the stem, and lies upon the ground, with the flowers arranged in a panicle. The calyx is monophyllous, tubular, and toothed at the margin; the corolla monophyllous and funnel-shaped, with the inferior border unilabiate, three-lobed, and spurred at the base. The fruit is a three-celled capsule, containing many seeds; during drying it is said to lose three-fourths of its weight.

This valuable plant is a native of the mountains of Malabar, where it springs up spontaneously in the forests after the removal of the undergrowth, and is very extensively cultivated by the natives. For a detailed account of culture, see *A. J. P.*, 1877, 605; also *P. J. Tr.*, 1888. The plant begins to yield fruit at the end of the fourth year, and continues to bear for several years afterwards. The capsules when ripe are picked from the fruit-stems, dried over a gentle fire, and separated by rubbing with the hands from the footstalks and adhering calyces.

Thus prepared, they are ovate-oblong, from three to ten lines long, from two to four thick, three-sided with rounded angles, obtusely pointed at both ends, longitudinally wrinkled, and of a yellowish-white color. The seeds which they contain are small, angular, irregular, rough as if embossed upon their surface, of a brown color, easily reduced to powder, and thus separable from the capsular covering, which, though slightly aromatic, is much less so than the seeds, and should be rejected when the medicine is administered. The seeds constitute about 74 parts per cent. by weight. According to Pereira, three varieties are distinguished in commerce: 1, the *shorts*, from three to six lines long, from two to three broad, browner and more coarsely ribbed and more highly esteemed than the others; 2, the *long-longs*, from seven lines to an inch in length by two or three lines in breadth, elongated, and somewhat acuminate; and 3, the *short-longs*, which are somewhat shorter and less pointed than the second variety.

The odor of cardamom is fragrant, the taste warm, slightly pungent, and highly aromatic. "Ovoid or oblong, from 10 to 15 Mm. long, obtusely triangular, rounded at the base, beaked, longitudinally striate; of a pale buff color, three-celled, with a thin, leathery, nearly tasteless pericarp, and a central placenta. The seeds are about 4 Mm. long, reddish brown, angular, rugose, depressed at the hilum, surrounded by a thin, membranous arillus, and have an agreeable odor and a pungent, aromatic taste." *U. S.* "Incinerated they should not yield more than 4 per cent. of ash." *Br.* Cardamom yields its virtues to water and alcohol, but more readily to the latter. The seeds contain 4·6 per cent. of volatile oil, 10·4 of fixed oil, 2·5 of a salt of potassium mixed with a coloring principle, 3·0 of starch, 1·8 of nitrogenous mucilage, 0·4 of yellow coloring matter, and 77·3 of ligneous fibre. (Trommsdorff.) The volatile oil is colorless, of an agreeable and very penetrating odor, and of a strong aromatic, burning, camphorous, and bitterish taste. It is dextrogyrate, and consists essentially of a terpene, $C_{10}H_{16}$, with small quantities of formic and acetic acids. From old specimens of oil Dumas and Peligot claim to have separated crystals of *terpene hydrate*, $C_{10}H_{20}O_2 + H_2O$, while Flückiger has obtained a crystalline deposit from Ceylon oil which he considers identical with common camphor. Weber (*Ann. Ch. und Pharm.*, 238, 98) speaks of finding a small amount of a crystalline non-volatile compound which fuses at 60°–61° C. Schimmel & Co. published in their semi-annual reports for April and October, 1897, some results of investigation of several varieties of cardamom oil. The terpenes of Ceylon oil they state to be *terpinene* and *dipentene;* both Ceylon and Bengal cardamom contain *cineol*, $C_{10}H_{18}O$; Malabar cardamom yields *terpineol* as well as cineol, while Siam cardamom yields a crystalline sediment composed of borneol and camphor in approximately equal proportions. The sp. gr. of the oil is between 0·92 and 0·94. It cannot be kept long without undergoing change, and finally, even though excluded from the air, loses its peculiar odor and taste. If ether be made to percolate through the powdered seeds, and the liquor obtained be deprived of the ether, a light greenish-brown fluid remains, consisting almost exclusively of the volatile and fixed oils. It has the odor of cardamom, and keeps better than the oil obtained by distillation. (*A. J. P.*, xxi. 116.) The seeds should be powdered only when wanted for use, as they retain their aromatic properties best while in the capsule.

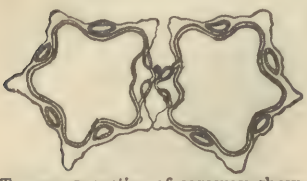
Cardamom fruit. *A*, section of seed; 1, outer membrane; 2, diagonal cells; 3, oil cells; 4, parenchyma; 5, palisade-like cells; 6, seed albumen; *B*, epidermis of seed, with hair; *C*, parenchyma of seed-coat.

Cardamoms are sometimes adulterated; G. W. Kennedy has seen nearly 4 per cent. of orange seeds and unroasted grains of coffee mixed with the cardamoms. (*A. J. P.*, 1872.) Solstein (1892) found that pure powdered cardamom yields 8·36 per cent. of ash; three commercial samples of powdered cardamom that he examined contained sodium carbonate.

Medical Properties and Uses. Cardamom is a warm and grateful aromatic, less heating and stimulating than some others belonging to the class, and very useful as an adjuvant or corrective of cordial, tonic, and purgative medicines. Throughout the East Indies it is largely consumed as a condiment. It was known to the ancients, and derived its name from the Greek language. In this country it is employed chiefly as an ingredient in compound preparations.

CARUM. U. S. (Br.) Caraway.

(CĀ′RŬM.)



"The fruit of Carum Carvi, Linné (nat. ord. Umbelliferæ)." *U. S.* "The dried fruit of Carum Carvi, Linn." *Br.*

Carui Fructus, *Br.*, Caraway Fruit; Fructus Carvi, *P. G.;* Cumin des Prés, Carvi, *Fr.;* Carvi, *It.;* Gemeiner Kümmel, Kümmel, *G.;* Alcaravea, *Sp.*

Gen. Ch. Fruit ovate-oblong, striated. *Involucre* one-leafed. *Petals* keeled, inflexed-emarginate. *Willd.*

Carum carui. Willd. *Sp. Plant.* i. 1470; *B. & T.* 121. This plant is biennial and umbelliferous, with a spindle-shaped, fleshy, whitish root, and an erect stem, about two feet in height, branching above, and furnished with doubly pinnate, deeply incised leaves, the segments of which are linear and pointed. The flowers are small and white, and in erect terminal umbels, which are accompanied with an involucre, consisting sometimes of three or four leaflets, sometimes of one only, and are destitute of partial involucre.

The caraway plant is a native of Europe, growing wild in meadows and pastures, and cultivated in many places. It has been introduced into this country. The flowers appear in May and June, and the seeds, which are not perfected till the second year, ripen in August. The root, when improved by culture, resembles the parsnip, and is used as food in the north of Europe. The seeds are the part used in medicine. They are collected by cutting down the plant, and threshing it on a cloth. Our markets are supplied partly from Europe, partly from our own gardens. The American seeds are usually rather smaller than the German. Under the name of *Ajowan*, the fruits of the *Carum ajowan*, Bentham & Hooker (*Ammi copticum*, Linn.), are largely used in India. They are $\frac{1}{10}$ to $\frac{1}{15}$ of an inch long, and resemble the fruits of common parsley, but are distinguished by their odor, and by their surface being very rough from numerous very minute tubercles. They contain about 4 per cent. of a volatile oil, which has the odor of the oil of thyme, and contains thymol: it may be used as an aromatic carminative. (See *Brit. Med. Journ.*, June 6, 1885.)

Transverse section of caraway, showing oil-tubes.

Caraway seeds (half-fruits) are about two lines in length, slightly curved, with five longitudinal ridges, which are of a light yellowish color, while the intervening spaces are dark brown. "Oblong, laterally compressed, about 4 or 5 Mm. long, usually separated into the two mericarps, which are curved, narrower at both ends, brown, with five yellowish, filiform ribs, and with six oil-tubes." *U. S.* "When incinerated the Fruit should not yield more than 8 per cent. of ash." *Br.* They have an agreeable aromatic smell, and a sweetish, warm, spicy taste. These properties depend on an essential oil, which they afford largely by distillation. (See *Oleum Cari.*) The residue is insipid. They yield their virtues readily to alcohol and more slowly to water.

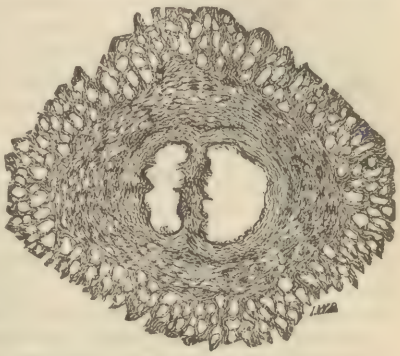
"Drawn caraway seeds," a term applied to such as have been recovered from the still residue after obtaining the volatile oil, are used to adulterate caraway; the exhausted "seeds" are much darker in color than are the genuine. (*P. J. Tr.*, 1896, 150.)

Medical Properties and Uses. Caraway is a pleasant stomachic and carminative, occasionally used in *flatulent colic*, and as an adjuvant or corrective of other medicines. The dose in substance is from a scruple to a drachm (1·3–3·9 Gm.). An infusion may be prepared by adding two drachms of the seeds to a pint of boiling water. The volatile oil, however, is most employed. (See *Oleum Cari.*) The seeds are baked in cakes, to which they communicate an agreeable flavor, while they stimulate the digestive organs.

CARYOPHYLLUS. U. S. (Br.) Cloves.

(CĂR-Y-Ǫ-PHŸL'LŲS.)

"The unexpanded flowers of Eugenia aromatica (Linné), O. Kuntze (nat. ord. Myrtaceæ)." *U. S.* "The dried flower-buds of Eugenia caryophyllata, Thunb." *Br.*



Caryophyllum, *Br.;* Caryophylli, *P. G.;* Caryophylli Aromatici; Girofle, Clous aromatiques, Clous de Girofles, *Fr.;* Gewurznelken, Nägelein, *G.;* Garofani, *It.;* Clavos de Espicia, *Sp.;* Cravo da India, *Portug.;* Kruidnagel, *Dutch;* Kerunfel, *Arab.*

Gen. Ch. Tube of the *calyx* cylindrical; limb, four-parted. *Petals* four, adhering by their ends in a sort of calyptra. *Stamens* distinct, arranged in four parcels in a quadrangular fleshy hollow, near the teeth of the calyx. *Ovary* two-celled, with about twenty ovules in each cell. *Berry* one- or two-celled, one- or two-seeded. *Seeds* cylindrical or half-ovate. *Cotyledons* thick, fleshy, convex externally, sinuous in various ways internally. *Lindley. De Cand.*

Eugenia caryophyllata. Willd. *Sp. Plant.* ii. 965; *B. & T.* 112.—*Caryophyllus aromaticus.* Linn. *Sp. Plant.*, 735; De Cand. *Prodrom.* iii. 262; Carson, *Illust. of Med. Bot.* i. 43, pl. 37. This small tree is one of the most elegant of those inhabiting the islands of India. It has a pyramidal form, is always green, and is adorned throughout the year with a succession of beautiful rosy flowers. The stem is of hard wood, and covered with a smooth, grayish bark. The leaves are about four inches in length by two in breadth, obovate-oblong, acuminate at

both ends, entire, sinuated, with many parallel veins on each side of the midrib, supported on long footstalks, and opposite. They have a firm consistence and a shining green color, and when bruised are highly fragrant. The flowers are disposed in terminal corymbose panicles, and exhale a strong, penetrating, and grateful odor.

The natural geographical range of the clove is extremely limited, being confined to the Molucca Islands. According to Flückiger, cloves were known in western Europe as early as the sixth century, long before the discovery of the Moluccas by the Portuguese. After the conquest of the Molucca Islands by the Dutch, the monopolizing policy of that commercial people led them to extirpate the trees in nearly all the islands except Amboyna and Ternate, which were under their immediate inspection. Notwithstanding their jealous vigilance, a French governor of the Isles of France and Bourbon, named Poivre, succeeded, in the year 1770, in obtaining plants from the Moluccas and introducing them into the colonies under his control. Five years afterwards the clove-tree was introduced into Cayenne and the West Indies, in 1803 into Sumatra, and in 1818 into Zanzibar. The latter place has, indeed, become the chief source of supply; the crop for 1889 was estimated at 13,000,000 pounds, worth, at the place of growth, 10 cents a pound.*

Transverse section of calyx-tube of clove.

The unexpanded flower-buds are the part of the plant employed under the ordinary name of cloves.† They are first gathered when the tree is about six years old. The fruit has similar aromatic properties, but much weaker. The buds are at first white, then become green, and then bright red, when they must be at once collected, which is done by hand-picking, or by beating the trees with bamboos and catching the falling buds. In the Moluccas they are said to be sometimes immersed in boiling water and afterwards exposed to smoke and artificial heat before being spread out in the sun. In Zanzibar, Cayenne, and the West Indies they are dried simply by solar heat.

Cloves appear to have been unknown to the ancients. They were introduced into Europe by the Arabians, and were distributed by the Venetians. After the discovery of the southern passage to India, the trade in this spice passed into the hands of the Portuguese, but was subsequently wrested from them by the Dutch, by whom it was long monopolized. The United States derive much of their supply from the West Indies and Guiana; but the great sources of cloves have been recently the islands of Zanzibar and Pemba, on the east coast of Africa. In 1872 the clove orchards in Zanzibar were nearly destroyed by a hurricane, but they have been replanted.‡ The Molucca cloves are said to be thicker, darker, heavier, more oily, and more highly aromatic than those cultivated elsewhere. They are known by the name of *Amboyna cloves*. The *Bencoolen cloves*, from Sumatra, are deemed equal, if not superior, by the English druggists. Cloves have been frequently examined microscopically and chemically to detect adulterations; the comparatively low price of this spice of late, however, has discouraged fraud of this kind. (See a paper by Prof. Kraemer, *Proc. A. P. A.*, 1894, 159.)

Properties. Cloves in shape resemble a nail with a round head with four spreading points beneath it. "About 15 Mm. long, dark brown, consisting of a subcylindrical, solid and glandular calyx-tube, terminated by four teeth, and surmounted by a globular head, formed by four petals, which cover numerous curved stamens, and one style. Cloves emit oil, when scratched, and have a strong, aromatic odor, and a pungent, spicy taste." *U. S.* "Incinerated they should not yield more than 7 per cent. of ash." *Br.* Their color is externally deep brown, internally reddish; their odor strong and fragrant; their taste hot, pungent, aromatic, and very permanent. The best cloves are large, heavy, brittle, and exude a small quantity of oil on being pressed or scraped with the nail. When light, soft, wrinkled, pale, and of feeble taste and smell, they are inferior. Those from which the essential oil has been distilled are

* Cloves from Cayenne, and from various West India islands, as Martinique, Guadeloupe, and Trinidad, have been for several years circulating in commerce.

† The stems of the flowers also enter commerce. They possess the odor and taste of the cloves, and, as they are worth only about one-fifth the price of the cloves and are said nearly to equal them in strength, they are largely used in the manufacture of ground cloves, as well as of oil of cloves. The French call them *griffes de girofles*.

‡ For detailed information as to method of growth, see *P. J. Tr.*, June, 1890.

sometimes fraudulently mixed with the genuine. In powdered cloves this fraud appears to be extensively practised, and its detection is almost impossible.

Trommsdorff obtained from 1000 parts of cloves 180 of volatile oil, 170 of a peculiar tannin,* 130 of gum, 60 of resin, 280 of vegetable fibre, and 180 of water. M. Lodibert afterwards discovered a fixed oil, aromatic and of a green color, and a white resinous substance which crystallizes in fasciculi composed of very fine diverging silky needles, without taste or smell, soluble in ether and boiling alcohol, and exhibiting neither alkaline nor acid reaction. This substance, called by M. Bonastre *caryophyllin*, was found in the cloves of the Moluccas, of Bourbon, and of Barbadoes, but not in those of Cayenne, from which, however, it has since been procured. To obtain it, the ethereal extract of cloves is treated with water, and the white substance thrown down is separated by filtration, and treated repeatedly with ammonia to deprive it of impurities. The most recent determination of its formula by Mylius (*Ber. Chem. Ges.*, 1873, p. 1053) makes it $C_{20}H_{32}O_2$. Dr. Theod. Martius obtains it cheaply by exposing cloves, previously deprived as far as possible of oil by distillation with water, to distillation at a higher temperature, redistilling the brown liquid obtained until the distillate nearly ceases to have the taste or smell of cloves, and then purifying the residue by washing with water, and treating it with boiling alcohol and animal charcoal repeatedly, until the caryophyllin, which is deposited by the alcohol on cooling, is perfectly white. (See *A. J. P.*, xxxii. 65.) M. Dumas has discovered another crystalline principle, which forms in the water distilled from cloves, and is gradually deposited. Like caryophyllin, it is soluble in alcohol and ether, but differs from that substance in becoming red when touched with nitric acid. M. Bonastre proposed for it the name of *eugenin*. (*Journ. de Pharm.*, xx. 565.) It has the formula $C_{10}H_{12}O_2$, and is isomeric with eugenol or eugenic acid, a constituent of oil of cloves. Water extracts the odor of cloves with comparatively little of their taste. All their sensible properties are imparted to alcohol; and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid if deprived of the oil by distillation with water, while the oil which comes over is mild. Hence it has been inferred that the pungency of this aromatic depends on a union of the essential oil with the resin. *Caryophyllic acid*, $C_{20}H_{32}O_6$, is obtained by gradually adding caryophyllin to fuming nitric acid, kept cool by immersing the vessel in water until crystals begin to separate; these are purified by dissolving them in ammonia, precipitating with hydrochloric acid, and redissolving in alcohol and crystallizing. For an account of the oil, see *Oleum Caryophylli*. The infusion and oil of cloves are reddened by nitric acid, and rendered blue by tincture of ferric chloride; facts of some interest, as morphine gives the same reactions.

Medical Properties and Uses. Cloves are among the most stimulant of the aromatics, but, like others of this class, act less upon the system at large than on the part to which they are immediately applied. They are sometimes administered in substance or infusion to relieve *nausea* and *vomiting*, correct *flatulence*, and excite *languid digestion;* but their chief use is to assist or modify the action of other medicines. They enter into several official preparations. Their dose in substance is from five to ten grains (0·33–0·65 Gm.).

The French Codex directs a *tincture of cloves* to be prepared by digesting for six days, and afterwards filtering, a mixture of four ounces of powdered cloves and sixteen of alcohol of 31° Cartier. Three ounces to the pint of alcohol is a sufficiently near approximation.

CASCARILLA. U. S., Br. Cascarilla.

(CĂS-CA-RĬL'LA.)

"The bark of Croton Eluteria, Bennett (nat. ord. Euphorbiaceæ)." *U. S.* "The dried bark of Croton Eluteria." *Br.*

Cascarillæ Cortex, *Br.* (1885), Cascarilla Bark; Cortex Cascarillæ, *P. G.;* Cortex Eluteriæ, Cortex Thuris: Chacrille, Ecorce éleuthérienne, Cascarille, *Fr.;* Cascarillrinde, Cascarilla, Kaskarillrinde, *G.;* Cascariglia, *It.:* Chacarilla, *Sp.*

Gen. Ch. MALE. *Calyx* cylindrical, five-toothed. *Corolla* five-petalled. *Stamens* ten to fifteen. FEMALE. *Calyx* many-leaved. *Corolla* none. *Styles* three, bifid. *Capsule* three-celled. *Seed* one. *Willd.*

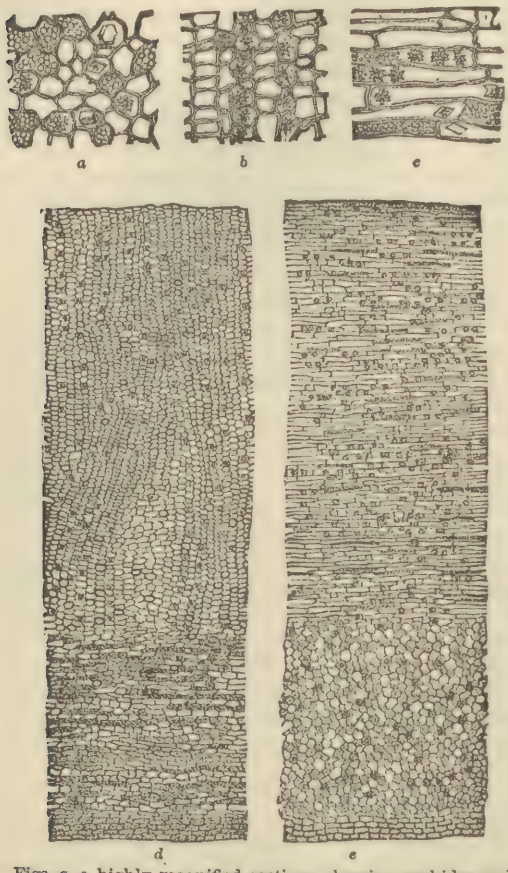
There has been much confusion in relation to the different species of Croton growing in the West Indies, and as to which of them the Cascarilla of commerce is to be ascribed. At present, however, it is generally admitted that this bark,† which is brought exclusively from the

* Wm. L. Peabody (1895) found the percentage of tannin in cloves to range from 10 to 13 per cent., and that it has the same chemical composition as gallotannic acid.

† Under the name of "cascarilla," also "*Quina morada,*" the bark of the *Pogonopus febrifugus* is said to be used in the Argentine Republic as a substitute for true cinchona bark. There has been separated from it a blue fluorescent substance, *moradin*, and an alkaloid, *moradeine*. (*P. J. Tr.*, xx. 854.)

Bahama Islands, is the product of *Croton eluteria;* and, though it is probable that the proper *C. cascarilla* may at one time have yielded a portion of its bark to commerce, at present little or none is derived from that species. The London College committed the error, which it afterwards corrected, of recognizing *C. cascarilla* of Don as the source of it. This botanist mistook the *Copalchi bark* of Mexico, which is produced by *Croton pseudo-china* of Schiede, and somewhat resembles cascarilla, for the genuine bark, and hence proposed to transfer the specific name of Cascarilla to the Mexican plant.*

Croton eluteria. Bennett, *Journ. of the Linn. Soc.* iv. 29; Daniell, *P. J. Tr.*, 2d ser., iv. 145, figured at p. 150; *B. & T.* 238.—*Clutia eluteria.* Woodv. *Med. Bot.* 3d ed., iv. 633, t. 223. As described by Dr. W. F. Daniell, who resided in the Bahama Islands, this, though commonly a shrub from three to five feet high, sometimes appears in the form of a small tree with a stem from four to eight inches in diameter.† The stem is straight, and marked at intervals with white or grayish stains. The leaves are petiolate, from two to three inches in length by an inch or more in breadth, often somewhat cordate at the base, obtusely acuminate, pale or grayish green above, and densely covered beneath with shining silvery scales, appearing white at a distance. They are smaller and narrower in the plants of arborescent growth. The flowers, which have a delicious odor, are monœcious, small, white, petiolate, and closely set in simple terminal or axillary spikes. The shrub is a native of the Bahamas, scarce at present in the island of New Providence, but still abundant in Andros, Long, and Eleutheria islands, from the latter of which it derived its botanical title. Daniell calls the plant *sweet-wood.* The name of *sea-side balsam* belongs to another species, *C. balsamiferum* of Linnæus, which grows in the Bahamas and other West India islands, and owes its name to the exudation of a balsamic juice from its young branches when wounded.



Croton cascarilla. Bennett, *Journ. of the Linn. Soc.* iv. 30.—*Clutia cascarilla.* Linn. *Sp. Plant.* ed. 1, 1042.—*Ricinoides elæagnifolia.* Catesby, *Hist. Carolin.* ii. t. 46. As described by Daniell, this is a shrub of from four to six feet, much branched, with a pale grayish-green stem, without the white stains of the former species. The leaves are petiolate, long, narrow, lanceolate, tapering towards each end, pointed, with flat or somewhat undular margins, above smooth and green, beneath pale and very hairy. The flowers are monœcious, in simple terminal spikes, with small white petals tinged with yellow. They are very fragrant. The plant is a native of the Bahamas, and is said also to grow in Hayti. In the Bahamas it is much scarcer than formerly, and is said by Dr. Daniell to yield at present none of the cascarilla of commerce, although much was formerly derived from it. This species seems to have been confounded by some with *Croton lineare* of Jacquin, which grows in the Bahamas and most of the West India islands, where it is known by the name of *wild rosemary*, owing probably in part to its fragrant smell, but still more to its narrow linear leaves with reflected margins.

Cascarilla is brought to this market from the West Indies, and chiefly, as we have been informed, from the Bahamas. It comes in bags or casks. We have observed it in commerce in two forms, so distinct as to merit the titles of varieties. In one, the bark is in rolled pieces of every size, from three or four inches in length and half an inch in diameter to the smallest fragments, covered externally with a dull whitish or grayish-white epidermis, which in many

* *Copalchi bark* has been mistaken not only for cascarilla, but also for a variety of cinchona. Portions of it, having been taken to Europe, attracted the attention both of pharmacologists and physicians. Two kinds were noticed: one, in small slender quills, of an ash color, bearing some resemblance to a variety of pale cinchona, but having the flavor of cascarilla, and burning with a similar odor; the other in larger quills, with a thick cork-like epidermis, very bitter, and yielding an aromatic odor when burnt. The former is the product of *Croton pseudo-china;* the latter is of unknown origin, but conjecturally referred to *C. suberosum.* Mr. J. E. Howard states that the quilled copalchi bark contains a bitter alkaloid, soluble in ether, and precipitable as a white hydrate from its acid solution. (*P. J. Tr.*, xiv. 319.) Copalchi bark is an aromatic tonic, employed in Mexico in intermittents, and capable of useful application in all cases requiring a mild aromatic bitter. Dr. Stark has employed it advantageously in feeble states of digestion with irritable bowels, and found it, in one or two cases, to exhibit antiperiodic properties. It may be given in infusion, made with half an ounce of the bark to a pint of water, in the dose of one or two fluidounces three times a day. (*Ed. Med. and Surg. Journ.*, April, 1849, p. 410; see, also, *P. J. Tr.*, 1886, p. 917.)

† The plant referred to in very early editions of this work as having been seen by Dr. Wright in Jamaica, and called by him *C. eluteria*, is, according to Mr. Bennett, a distinct species, *C. sloanei*, which was confounded by Linnæus with the genuine cascarilla plant, under the name of *Clutia eluteria.* The genuine plant was first described by him in his *Hortus Cliffortianus* (pp. 486–7), from a specimen in Cliffort's herbarium in the British Museum, and afterwards apparently confused with a Jamaica specimen sent to him by Patrick Brown, from the latter of which the description of his *Clutia eluteria* was drawn up, which is quite inapplicable to the original plant. It is the *C. sloanei* also that was described by Schwartz in his *Flora Indiæ Occidentalis* (p. 1183), under the name of *Croton eluteria*, and probably the same that was figured by Dr. Carson in his *Illust. of Med. Bot.* ii. 34, pl. 78. (See *P. J. Tr.*, 1859, pp. 132–3.)

portions is partially, sometimes wholly removed, leaving a dark brown surface, while the inner surface has a chocolate color, and the fracture is a reddish brown. The small pieces are sometimes curled, but have a distinct abrupt edge as if broken from the branches. The second variety consists entirely of very small pieces, not more than an inch or two in length, very thin, without the white epidermis, not regularly quilled, but curved more or less in the direction of their length, often having a small portion of woody fibre attached to their inner surface, and appearing precisely as if shaved by a knife from the stem or branches. Whether these two varieties are derived from distinct species, or differ only from the mode of collection, it is difficult to determine. A. W. Southall describes a bark (believed to belong to the genus Cascarilla, and obtained from Colombia) in *P. J. Tr.*, 1894, 574. The official description of cascarilla is as follows: "In quills or curved pieces about 2 Mm. thick, having a grayish, somewhat fissured, easily detached, corky layer, more or less coated with a white lichen, the uncoated surface being dull brown, and the inner surface smooth. It breaks with a short fracture, having a resinous and radially striate appearance. When burned, it emits a strong, aromatic, somewhat musk-like odor; its taste is warm and very bitter." *U. S.* "Fracture short, and resinous; the transverse section exhibits under a lens dark reddish-brown bast traversed by thin whitish medullary rays, but no groups of sclerenchymatous cells." *Br.*

Figs. *a*, *c*, highly magnified sections, showing raphides and starch granules and a bast-cell; *b*, longitudinal section highly magnified, showing raphides and starch granules; *d*, transverse section moderately magnified; *e*, longitudidal section.

Properties. Cascarilla has an aromatic odor, rendered much more distinct by friction, and a warm, spicy, bitter taste. It is brittle, breaking with a short fracture. When burnt it emits a pleasant odor, closely resembling that of musk, but weaker and more agreeable. This property serves to distinguish it from other barks. It was analyzed by Trommsdorff, and more recently by M. Duval, of Lisieux, in France. The constituents found by the latter were albumen, a peculiar kind of tannin, a bitter crystallizable principle called *cascarillin*, a red coloring matter, fatty matter of a nauseous odor, wax, gum, volatile oil, resin, starch, pectic acid, potassium chloride, a salt of lime, and lignin. The oil, according to Trommsdorff, constitutes 1·6 per cent., is of a greenish-yellow color, has a penetrating odor analogous to that of the bark, and is of the sp. gr. 0·938. It is apparently a mixture of two oils, the first of which is a terpene boiling at 172° C. and of the sp. gr. 0·862, and the other a higher-boiling oxygenated constituent. Gladstone (*Jahresb. der Pharm.*, 1872, 450) gives to the hydrocarbon of cascarilla oil the composition of oil of turpentine. To obtain cascarillin, M. Duval treated the powdered bark with water, added lead acetate to the solution, separated the lead by hydrogen sulphide, filtered, evaporated with the addition of animal charcoal, filtered again, evaporated at a low temperature to a syrupy consistence, and, having allowed the semi-liquid substance thus obtained to harden by cooling, purified it by twice successively treating it, first with a little cool alcohol, to separate the coloring and fatty matters, and afterwards with boiling alcohol and animal charcoal. The last alcoholic solution was allowed to evaporate spontaneously. Thus obtained, cascarillin is white, crystalline, inodorous, bitter, very slightly soluble in water, soluble in alcohol and ether. (*Journ. de Pharm.*, 3e sér., viii. 96.) It melts at 205° C. (401° F.), is not volatile

nor a glucoside. Its composition answers to the formula $C_{12}H_{18}O_4$. Dr. P. E. Alessandri regards *cascarilline* as an alkaloid, and obtains it economically by mixing powdered cascarilla with sufficient 3 per cent. aqueous solution of oxalic acid to cover it, shaking the mixture, and heating it to 140° F., then allowing it to cool, expressing the mixture and saturating the filtered liquor with ammonia, then evaporating at a low temperature to two-thirds of its bulk, allowing it to cool, and separating any deposit. The clear liquid is then shaken with ether; this takes up the cascarilline, which may be obtained through evaporation of the ethereal liquid. (*L'Orosi*, v. 1; *P. J. Tr.*, 1882, 993.) R. A. Cripps was unable to obtain the alkaloid by Alessandri's method, and suggests that the bitterness of the so-called cascarilline might be due to adherent resin. (*P. J. Tr.*, 1886, 1103.) Either alcohol or water will partially extract the active matters of cascarilla; but diluted alcohol is the proper menstruum. Naylor and Littlefield have reviewed the processes of Duval and Alessandri for preparing cascarilline, and find that Duval's method gives the purer product. They find its melting point to be 203·5° C., and give it the formula $C_{16}H_{24}O_5$. (*Year-Book of Pharm.*, 1896, 301.) W. A. H. Naylor subsequently found *betaine*. (*P. J. Tr.*, 1898, 279.)

Medical Properties and Uses. This bark is aromatic and tonic. It was known in Germany so early as the year 1690, and was much used as a substitute for Peruvian bark by those who were prejudiced against that febrifuge in the treatment of *remittent and intermittent fevers*. It has, however, lost its reputation, and is now employed only where a pleasant and gently stimulant tonic is desirable, as in *dyspepsia*, *chronic diarrhœa* and *dysentery*, *flatulent colic*, and other cases of debility of the stomach or bowels. It is said to promote the flow of milk in the lower animals, and has been proposed with a view to the same effect in the human subject. It is sometimes advantageously combined with the more powerful bitters. It may be given in powder or in infusion. The dose of the former is from a scruple to half a drachm (1·3–1·95 Gm.), which may be repeated several times a day. Prof. Procter published a formula for a fluid extract which contains the virtues of a troyounce of the bark in a fluidounce. (*A. J. P.*, 1863, p. 113.) In consequence of its pleasant odor when burnt, some smokers mix it in small quantity with their tobacco; but it is said to occasion vertigo and intoxication.

CASSIA FISTULA. U. S. (Br.) Cassia Fistula. [Purging Cassia.]

(KĂS'SI-Ą FĬS'TŪ-LĄ.)

"The fruit of Cassia Fistula, Linné (nat. ord. Leguminosæ)." *U. S.* "The pulp obtained from the pods of Cassia Fistula, Linn." *Br.*

Cassiæ Pulpa, *Br.;* Cassia Pulp; Fructus Cassiæ Fistulæ; Casse officinale, Casse en Bâtons, Pulpe de Casse, Casse mondée, Casse, *Fr.;* Rohrenkassie, Purgiercassie, Fistelkassie, *G.;* Cassia, *It.;* Cana Fistula, *Sp.*

Gen. Ch. Calyx five-leaved. *Petals* five. *Anthers*, three upper sterile, three lower beaked. *Willd.*

The tree which yields the purging cassia is ranked by some botanists as a distinct genus, separated from the Cassia, and denominated *Cathartocarpus*. (See *Lindley's Flor. Med.*, 262.)

Cassia fistula. Willd. *Sp. Plant.* ii. 518; Carson, *Illust. of Med. Bot.* i. 24, pl. 26; *B. & T.* 87.—*Cathartocarpus fistula.* Persoon, *Synops.* i. 459. This is a large tree, rising to the height of forty or fifty feet, with a trunk of hard, heavy wood, dividing towards the top into numerous spreading branches, and covered with a smooth ash-colored bark. The leaves are commonly composed of five or six pairs of opposite leaflets, which are ovate, pointed, undulated, smooth, of a pale green color, from three to five inches long, and supported upon short petioles. The flowers are large, of a golden yellow color, and arranged in long, pendent, axillary racemes. The fruit consists of long, cylindrical, woody, dark-brown, pendulous pods, which when agitated by the wind strike against each other and produce a sound that may be heard at a distance. This species of Cassia is a native of Upper Egypt and India, whence it is generally supposed to have been transplanted to other parts of the world. It is at present very extensively diffused through the tropical regions of the old and new continents, being found in Insular and Continental India, Cochin-China, Egypt, Nubia, the West Indies, and the warmer parts of the continent of America. The fruit is the official portion of the plant. It is imported from the East and West Indies, chiefly the latter, and from South America.

Properties. Cassia pods are a foot or more in length, straight, or but slightly curved, cylindrical, less than an inch in diameter, with a woody shell, externally of a dark-brown color, and marked with three longitudinal shining bands, extending from one end to the other, two of which are in close proximity, appearing to constitute a single band, and the third is on the opposite side of the pod. These bands mark the place of junction of the valves of the legume,

and are represented as sometimes excavated in the form of furrows. There are also circular depressions at unequal distances. The official description is as follows. "Cylindrical, 40 to 60 Cm. long, nearly 25 Mm. in diameter, blackish-brown, somewhat veined, the sutures smooth, forming two longitudinal bands; indehiscent, internally divided transversely into numerous cells, each containing a reddish-brown, glossy, flattish-ovate seed imbedded in a blackish-brown sweet pulp; odor resembling that of prunes." *U. S.* The pods brought from the East Indies are smaller, smoother, have a blacker pulp, and are more esteemed than those from the West Indies. We have seen pods in the American market sold as cassia pods, which were an inch and a half in diameter, flattened on the sides, exceedingly rough on the outer surface, and marked by three longitudinal very elevated ridges, corresponding to the bands or furrows of the common cassia. The pulp was rather nauseous, but in other respects seemed to have the properties of the official purging cassia. They corresponded exactly with a specimen of the fruit of *Cassia brasiliana* brought from the West Indies, and were probably derived from that plant.

The heaviest pods, and those which do not make a rattling noise when shaken, are to be preferred, as they contain a larger portion of the pulp, which is the part employed. This should be black and shining and have a sweet taste. It is apt to become sour if long exposed to the air, or mouldy if kept in a damp place. The pulp is extracted from the pods by first bruising them, then boiling them in water, and afterwards evaporating the decoction; or, when the pods are fresh, by opening them at the sutures and removing the pulp by a spatula.

Cassia pulp has a slight rather sickly odor, and a sweet mucilaginous taste. From the analysis of M. Henry it appears to contain sugar, gum, a substance analogous to tannin, a coloring matter soluble in ether, traces of a principle resembling gluten, and a little water.

Medical Properties and Uses. Cassia pulp is laxative, and may be advantageously given in small doses in cases of *habitual costiveness*. In quantities sufficient to purge, it occasions nausea, flatulence, and griping. In this country it is rarely prescribed, except as an ingredient in the official confection of senna, which is a pleasant and useful laxative preparation. The dose of the pulp as a laxative is one or two drachms (3·9–7·8 Gm.), as a purge one or two ounces (31·1–62·2 Gm.).

CASTANEA. U. S. Castanea. [Chestnut.]

(CĂS-TĀ'NĒ-Ą.)

"The leaves of Castanea dentata (Marshall), Sudworth (nat. ord. Cupuliferæ), collected in September or October, while still green." *U. S.*

Folia Castaneæ; Feuilles de Châtaignier, Feuilles de Marronnier, Châtaigne, *Fr.;* Kastanie, Kastanienblätter, *G.;* Castagna, *It.;* Castaña, *Sp.*

Gen. Ch. MALE. *Ament* naked. *Calyx* none. *Corolla* five-petalled. *Stamens* ten to twenty. FEMALE. *Calyx* five- or six-leaved, muricate. *Corolla* none. *Germs* three. Stigma pencil-formed. *Nuts* three, included in an echinated calyx. *Willd.*

This is a very small genus, separated from the original Fagus of Linn., including only two or three recognized species; the *Castanea vesca* of Europe and North America, and *C. pumila* of the United States, which will be found described in PART II. of the present work. The European and American chestnut-trees are often spoken of under the same botanical title; as no points of difference can be found between them which all botanists are willing to recognize as authorizing distinct specific designations. The late Dr. Geo. B. Wood, however, believed, for reasons given below, that they are distinct trees, differing in origin, and as much entitled to distinct names as the European and American white oaks, or indeed any other analogous species of the two continents. The general aspect of the two trees is such that the accustomed eye will at a glance recognize the difference. The specific difference of the American chestnut-tree from the European is denied by many botanists, notably the late Prof. Asa Gray. Recently, however, the trend of professional opinion seems to be towards the view which was held by Prof. Geo. B. Wood, that the two trees really represent distinct species. The general aspect of the two trees is certainly very diverse: in the European chestnut the main branches are horizontal, and the tree when mature has a very round and formal head; whilst the American chestnut, with its slender, twiggy shoots, and its gnarled and twisted branches, is very irregular in its annual growth and in its ultimate form. The leaves of the European chestnut are more erect and less deeply serrate than those of the American, and usually have a rounded or heart-shaped base; whereas the base of the American leaf is commonly somewhat pointed. Again, the European leaf is commonly stellately tomentose on the under surface, at least when young. The much greater size and the somewhat peculiar shape of the fruit of the European, or, as it

is commonly called in this country, the Spanish chestnut, are sufficient specific characters. Besides, the European tree does not lose its distinctive character under complete change of circumstances. Transplanted into North America, and propagated by the seed, it has retained, through a succession of generations, the original size of its fruit, which, had the tree been of the same species as the American, would have almost certainly more or less deteriorated.

*Castanea dentata.** Willd.; Michaux, *N. American Sylva*, iii. 9.—*Castanea americana.* Persoon. (See *Mérat and De Lens.*) The American chestnut is, under favorable circumstances, one of our largest and most magnificent native trees. Michaux states that he had measured several trees the trunks of which at six feet from the ground were fifteen or sixteen feet in circumference, and their stature equal to that of the loftiest trees of the forest. So great a size, however, is rare. Its leaves, which are the official portion, serve also at once to distinguish the tree. They are from four to ten inches long by about two in breadth, oblong-elliptical, sharp at the end, strongly and somewhat unequally serrated, with prominent parallel nerves beneath, of a brilliant color and firm consistence. The only leaves that are liable to be confounded with them are those of the chestnut-oak, which have a very similar form and structure, but are at once distinguishable by the rounded crenate projections on the edge, instead of the sharp serratures of the chestnut. The male flowers are whitish, and disposed on axillary peduncles, four or five inches long; the fertile aments similarly disposed, but less conspicuous. The fruit is a spherical burr, an inch or two in diameter, and very prickly, containing two or three brown nuts, the appearance of which is too well known to require description here. When perfectly ripe, it opens and lets fall the seeds. The bark is very peculiar and characteristic in its appearance, with a longitudinal arrangement of its fibres. The wood is firm and elastic, though not compact, with a remarkable power of resisting decomposition from the weather, and therefore very valuable for posts and rails in fencing. It is not well fitted for fuel, in consequence of a great disposition to snap in the fire, and to throw off burning particles to a considerable distance. The chinquapin (*C. pumila*, Mill) is described in PART II.

The American chestnut is spread largely through the eastern portions of the United States, from New Hampshire to the mountainous districts of Virginia, North and South Carolina, Georgia, and Tennessee, though rare in the maritime parts of Virginia and the other Southern States. The leaves should be collected after maturity, and before the autumnal decay.

The European species is distributed in the south of Europe very much as the American is with us, preferring hilly regions, and abounding in Spain, the south and west of France, Switzerland, and Italy. It sometimes attains an enormous magnitude. Michaux describes one, growing at Sancerre in France, which at six feet from the ground is thirty feet in circumference, and six hundred years ago was known as the *Great Chestnut.* Though supposed to be more than one thousand years old, its trunk is perfectly sound, and its branches are annually loaded with fruit. Much larger than this is the celebrated chestnut of Mount Etna, of which the trunk is said to be one hundred and sixty feet in circumference, though hollow in the centre, so that the tree lives by its bark. (*Mérat and De Lens.*) In Europe the young chestnut is much used for making hoops, for which it is preferred to all other wood on account of resisting the effects of air and moisture. For this purpose it is much cultivated in Europe, and cut when large enough. But the tree is still more valuable on account of its large nuts, which are much used as food, being a favorite on the table of the rich, and often the main dependence of the poor peasant, who considers himself well off when possessed of a few healthy chestnut-trees. Whole provinces are said to be supported by this fruit. Though cultivated in small numbers in this country, they have not been so extensively introduced as they ought to be, chiefly, in all probability, from their difficulty of propagation. The inner bark of the chestnut has been vaunted in Europe as a remedy in *dysentery.* (*Mérat and De Lens.*)

Properties. The leaves, which have already been described, are so flexible and tenacious that it is difficult to powder them. In preparing them for the action of a solvent, they must be comminuted by cutting and bruising them in a mortar. They are not, therefore, well fitted for percolation. (*Maisch.*) They have little smell, and a slightly astringent and scarcely bitterish taste, so that they are not offensive to children. They yield their virtues freely to water, and probably less so to alcohol. John B. Turner found in chestnut leaves chlorophyll, tannin, gallic acid, gum, and albumen. (*A. J. P.*, 1879, p. 542.) In addition to these constituents, L. J. Steltzer found potassium, calcium, magnesium, and iron carbonates, chlorides, and phosphates, and a trace of resin and fat. (*A. J. P.*, 1880, p. 294.)

* *Castanea vesca*, var. *americana*, is the name given by Michaux to the American chestnut; but previous to his naming it, Marshall had described it in 1775 as *Fagus castanea dentata.*

Medical Uses. The only remedial use of the leaves, so far as we have learned, has been in the treatment of *whooping-cough*, as originally proposed by G. C. Close in 1862. Their effects on the system do not appear to have been carefully studied; but their sensible properties do not indicate the possession of any extraordinary physiological power. The leaves may be administered in infusion or in fluid extract. Dr. Unzicker prepared an infusion with three or four drachms of the leaves and a pint of boiling water, and gave of it, well sweetened, as much as the child would drink.

CATECHU. U. S., Br. Catechu.

(CĂT'Ę ĊHŪ—kăt'ę-kū.)

"An extract prepared from the wood of Acacia Catechu (Linné fil.), Willdenow (nat. ord. Leguminosæ)." *U. S.* "An extract of the leaves and young shoots of Uncaria Gambier, Roxb." *Br.*

Catechu Pallidum, Pale Catechu, Cutch, Terra Japonica, Catechu Nigrum; Cachou, *Fr.;* Catechu, Katechu, Pegu Catechu, *G.;* Catecu, Catciu, Catto, *It.;* Catecu, *Sp.;* Cutt, *Hindostanee.*

The British Pharmacopœia has entirely rejected the proper catechu, which in the former edition was recognized under the inappropriate name of Catechu Nigrum, retaining by the name of Catechu a product which, though analogous to catechu, is entirely distinct, being derived from a different plant, and known commonly by a different name, that, namely, of *gambir.** We treat in the text of the proper catechu, and in a note of gambir among the catechus not recognized by the U. S. Pharmacopœia.

Acacia catechu. Willd. *Sp. Plant.* iv. 1079; Carson, *Illust. of Med. Bot.* i. 32, pl. 24; *B. & T.* 95. According to Mr. Kerr, whose description has been followed by most subsequent writers, *Acacia catechu* is a small tree, seldom more than twelve feet in height, with a trunk one foot in diameter, dividing towards the top into many close branches, and covered with a thick, rough, brown bark. The leaves, which stand alternately upon the younger branches, are composed of from fifteen to thirty pairs of pinnæ nearly two inches long, each of which is furnished with about forty pairs of linear leaflets, beset with short hairs. At the base of each pair of pinnæ is a small gland upon the common footstalk. Two short recurved spines are attached to the stem at the base of each leaf. The flowers are in close spikes, which arise from the axils of the leaves, and are about four or five inches long. The fruit is a lanceolate, compressed, smooth, brown pod, with an undulated thin margin, and contains six or eight roundish flattened seeds, which when chewed emit a nauseous odor.

This species of Acacia is a native of the East Indies, growing abundantly in various provinces of Hindostan, and in the Burmese Empire. Pereira says that it is common in Jamaica. Like most others of the same genus, it abounds in astringent matter, which may be extracted by decoction. Catechu is an extract from the wood of the tree.

This drug had been long known before its source was discovered. It was at first called *terra Japonica*, under the erroneous impression that it was an earthy substance derived from Japan. When ascertained by analysis to be of vegetable origin, it was generally considered by writers on the Materia Medica to be an extract of the *betel nut*, which is the fruit of a species of palm, denominated *Areca catechu*. Its true origin was made known by Mr. Kerr, assistant surgeon of the civil hospital in Bengal, who had an opportunity of examining the tree from which it was obtained, and observing the process of extraction. According to Mr. Kerr, the manufacturer, having cut off the exterior white part of the wood, reduces the interior brown or reddish-colored portion into chips, which he then boils in water in unglazed earthen vessels till all the soluble matter is dissolved. The decoction thus obtained is evaporated first by artificial heat, and afterwards in the sun, till it has assumed a thick consistence, when it is spread out to dry upon a mat or cloth, being, while yet soft, divided by means of a string into square or quadrangular pieces. The account subsequently given by Dr. Royle, of the preparation of the extract in Northern India, is essentially the same. The process, as he observed it, was completed by the pouring of the extract into quadrangular earthen moulds. It is said that the unripe fruit and leaves are also sometimes submitted to decoction. Our countryman the Rev. Howard Malcom states, in his "Travels in South-Eastern Asia," that catechu is largely prepared from the wood of *Acacia catechu* near Prome, in Burmah. Two kinds, he observes, are

* In a series of tests made with gambir and catechu, as they occur in the American markets, by Henry Trimble (*A. P. A.*, 1888), gambir was found to be more uniform in its constitution, and to be superior in the amount of available astringent principles; also to have the advantage of being more easily powdered. This is in accord with the studies of E. S. Reider (*A. J. P.*, April, 1889), who finds that the catechu of the American market usually contains very small amounts of catechin and large amounts of impurities.

prepared from the same tree; one *black*, which is preferred in China, and the other *red*, which is most esteemed in Bengal. At present, however, it would seem that three colors of catechu are prepared: the light-red or red, which is considered best and is especially employed in Burmah and India to chew with the betel nut; the dark-red and black, which are made especially for European and American markets, and which are apt to suffer adulteration *en route* in China.

The name *catechu* in the native language signifies the *juice of a tree*, and appears to have been applied to astringent extracts obtained from various plants. According to the U. S. Pharmacopœia, however, the term is properly restricted to the extract of *Acacia catechu;* as it was not intended to recognize all the astringent products which are floating in Asiatic commerce; and those from other sources than the Acacia, though they may occasionally find their way into our shops, do so as an exception to the rule. A minute account of the diversified forms and exterior characters which official catechu presents as produced in different localities would tend to perplex the reader rather than to serve any good practical purpose. These characters are, moreover, frequently changing, as the drug is procured from new sources, or as slight variations may occur in the mode of its preparation. Commerce is chiefly supplied with catechu from Bahar, Northern India, and Nepaul through Calcutta, from Canara through Bombay, and from the Burmese dominions. We derive it directly from Calcutta, or by orders from London, and it is sold in our markets without reference to its origin. It is frequently called *cutch* by the English traders, a name derived from the Hindostanee word *cutt*.*

* In order not to embarrass the text unnecessarily, we have thrown together, in the form of a note, the following observations upon the varieties of catechu; those being first considered which are probably derived from *Acacia catechu*, and therefore recognized as official in the U. S. Pharmacopœia.

1. *Official Catechu. U. S.*

The following, so far as we have been able to distinguish them, are the varieties of official catechu to be found in the markets of Philadelphia.

1. *Plano-convex Catechu. Cake Catechu.* This is in the form of circular cakes, flat on one side, convex on the other, and usually somewhat rounded at the edge, as if the soft extract had been placed in saucers, or vessels of a similar shape, to harden. As found in the retail shops, it is generally in fragments, most of which, however, exhibit some evidences of the original form. The cakes are of various sizes, from two or three to six inches or more in diameter, and weighing from a few ounces to nearly two pounds. Their exterior is usually smooth and dark brown; but we have seen a specimen in which the flat surface exhibited impressions as if produced by coarse matting. The color internally is always brown, sometimes of a light yellowish brown or chocolate color, but more frequently dark reddish brown, and sometimes almost black. The cakes are almost always more or less cellular in their interior; but in this respect great diversity exists. Sometimes they are very porous, so as almost to present a spongy appearance, sometimes compact and nearly uniform; and this difference may be observed even in the same piece. The fracture is sometimes rough and dull, but in the more compact parts is usually smooth and somewhat shining; and occasionally a piece split in one direction will exhibit a spongy fracture, while in another it will be shining and resinous, indicating the consolidation of the extract in layers. This variety of catechu is often of good quality. It is common at present in our market, but we have been unable to trace its origin accurately. There can be little doubt, from its internal character, that it comes from the East Indies, and is the product of *A. catechu;* but no accounts that we have seen of the preparation of the drug, in particular geographical sites, indicate this particular shape; and it is not impossible that portions of it may be formed out of other varieties of catechu by a new solution and evaporation.

2. *Pegu Catechu.* This is the product derived from the Burmese dominions, and named from that section of the country whence it is exported. It enters commerce, probably in general through Calcutta, in large masses, sometimes of one cwt., consisting of layers of flat cakes, each wrapped in leaves, said to be those of the *Nauclea brunonis*. In this form, however, we do not see it in the shops, but almost always in angular, irregular fragments, in which portions of two layers sometimes cohere with leaves between them, indicating their origin. It is characterized by its compactness, shining fracture, and blackish-brown or dark port-wine color, so that when finally broken it bears considerable resemblance to kino. This is an excellent variety of catechu, and is not unfrequent in commerce.

3. *Catechu in Quadrangular Cakes.* This is scarcely ever found in commerce in its complete form, and the fragments are often such that it would be impossible to infer from them the original shape of the cake. This is usually between two and three inches in length and breadth, and somewhat less in thickness, of a rusty-brown color externally, and dark brown or brownish gray within, with a somewhat rough and dull fracture, but, when broken across the layers in which it is sometimes disposed, exhibiting a smoother and more shining surface. Guibourt speaks of the layers as being blackish externally and grayish within, and bearing some resemblance to the bark of a tree, a resemblance, however, which has not struck us in the specimens which have fallen under our notice. There is little doubt that this variety comes from the provinces of Bahar and Northern India, where the preparation of the drug was witnessed by Mr. Kerr and Dr. Royle, who both speak of it as being brought, when drying, into the quadrangular form. It has been called *Bengal catechu*, because exported from that province.

Pale catechu, so far as the term is not applied to *gambir*, may be considered as belonging to this variety. A specimen with this name, which was sent from India to the London exhibition of 1862, and which Dr. G. B. Wood had an opportunity of examining, was in oblong rectangular pieces, or fragments of such pieces, about three and a half inches long by an inch and a half in breadth, of a dirty yellowish color within, and an earthy fracture, quite free from gloss, and bearing a much stronger resemblance to gambir than to ordinary catechu.

4. *Catechu in Balls.* We have seen this in two forms—one consisting of globular balls about as large as an orange, very hard and heavy, of a ferruginous aspect externally, very rough when broken, and so full of sand as to be gritty under the teeth; the other in cakes, originally, in all probability, globular, and of about the same dimensions, but flattened and otherwise pressed out of shape before being perfectly dried, sometimes adhering two together, as happens with the lumps of Smyrna opium, and closely resembling in external and internal color, and in the character

Properties. Catechu, as it comes to us, is in masses of different shapes, some in balls more or less flattened, some in circular cakes, some saucer-shaped, others cubical or oblong, or quite irregular, and of every grade in size, from small angular pieces, which are evidently fragments of the original cakes, to lumps which weigh one or two pounds. The color is exter-

of their fracture, the quadrangular variety last described. The former kind is rare, and the specimens we have seen had been twenty years in the shop, and had very much the appearance of a factitious product. The latter is in all probability the kind known formerly as the *Bombay catechu*; as Dr. Hamilton, and, more recently, Major Mackintosh, in describing the mode of preparing catechu on the Malabar coast, of which Bombay is the entrepôt, say that, while the extract is soft, it is shaped into balls about the size of an orange.

2. Catechus not recognized in the U. S. Pharmacopœia.

1. **Catechu,** *Br. Gambir. Terra Japonica. Pale Catechu.* Many years ago, Dr. Campbell, a medical officer at Bencoolen, called attention to the astringent properties of an extract chewed by the Malays with *pinang* and *siren* (betel nut). This led to an increasing use of the article, until now thousands of tons are yearly shipped to Europe and America. The plant from which it is obtained, called by Mr. Hunter, who first minutely described it, *Nauclea gambir*, but by Roxburgh, De Candolle, and others, *Uncaria gambir*, is a climbing shrub of the natural order Rubiaceæ of Jussieu, Cinchonaceæ of Lindley. (*B. & T.* 139.) It is a native of Malacca, Sumatra, Cochin-China, and other parts of Eastern Asia, and is largely cultivated in the islands of Bintang, Singapore, and Prince of Wales. The gambir is prepared by lopping off the leaves, shoots, and twigs of the plant, chopping them into pieces, and throwing them into an iron pot filled with boiling water. When the leaves are exhausted and the liquid sufficiently thick, it is poured into small wooden tubs, and so soon as sufficiently cool, a half-closed hand is plunged into the semi-fluid and a piece of light wood shaped like an elongated dice-box rapidly worked up and down in the hollow formed by the hand. The extract begins to thicken by a process which is compared to crystallization. The mass is finally turned out, and cut into cubes, which are put upon trays and smoke-dried. (See also *P. J. Tr.*, 1892, 1003.)

Gambir is in cubes with sides about an inch square, is light and porous, so that it floats when thrown in water, is deep yellowish or reddish brown externally, but pale yellowish within, presents a dull earthy surface when broken, is inodorous, and has a strongly astringent, bitter and subsequently sweetish taste. It softens and swells up when heated, and leaves a minute proportion of ashes when burnt. It is partially soluble in cold water, and almost wholly so in boiling water, which deposits a portion upon cooling. Duhamel, Ecky, and Procter dissolved 87·5 per cent. of it in cold water by means of percolation. (*A. J. P.*, xvi. 166.) Nees von Esenbeck found it to consist of from 36 to 40 per cent. of catechu-tannic acid, a peculiar principle called *catechuin*, *catechin*, or *catechuic acid*, gum or gummy extractive, a deposit like the cinchonic red, and 2·5 per cent. of lignin. *Catechin*, when perfectly pure, is snow-white, of a silky appearance, crystallizable in fine needles, melting at 217° C., unalterable in the air if dry, fusible by heat, very slightly soluble in cold water, with which it softens and swells up, soluble in boiling water, which deposits it on cooling, and soluble also in alcohol and ether. It very slightly reddens litmus paper, and, though coloring the solution of chloride of iron green, and producing with it a grayish green precipitate, differs from tannic acid in not affecting a solution of gelatin. It bears considerable analogy to gallic acid in its relations to the metallic salts, but does not, according to Neubauer, bear the same relation to the tannic acid of catechu that gallic acid does to that of galls. On the contrary, instead of resulting from the oxidation of tannic acid, it is by heat converted into a substance analogous to tannin. (*A. J. P.*, xxviii. 329 and 331; from *Liebig's Annalen*, xcvi. 337.) The very great discordance of different authors as to its formula seems to be explained by some recent experiments of Etti (*Liebig's Ann.*, 186, p. 327), who shows that *catechin*, $C_{19}H_{18}O_8$, readily gives at 100° C. (212° F.), or even when kept for some time over sulphuric acid, an anhydride, $C_{38}H_{34}O_{15}$, and at 160° C. (320° F.) a second anhydride, $C_{38}H_{32}O_{14}$, which, mixed in varying proportions, explain the varying results. Gautier (*Bulletin*, 30, 567) finds three different catechins separable by their different solubility in water, all of them crystallizable. These are: *a-catechin*, $C_{40}H_{38}O_{18} + 2H_2O$, melting at from 204°–205° C., and present in gambir to the amount of 12 per cent.; *b-catechin*, $C_{47}H_{38}O_{16} + H_2O$, melting at from 176°–177° C., and present in gambir to the amount of 2 per cent.; and *c-catechin*, $C_{40}H_{38}O_{16} + H_2O$, melting at 163° C., and present in gambir to the amount of 6·5 per cent.

Good gambir should occur in a hard compact mass, breaking up, when the adhering mat is removed, into distinct cubes of a brownish-black color externally and a deep mahogany-red with an occasional streak of yellow internally. It should not steam when the mat is opened. From this quality it grades down to a stuff which has been prepared by mixing the material obtained by reboiling the exhausted leaves with various mixtures. This lowest grade is not in cubes, steams when opened, frequently shows large patches of black or dirty blue color, and often has a sour fetid smell; its color varies from black to light-brown color. The varieties between the two extremes are very great; sometimes gambir occurs in solid mass of fair quality; sometimes the cubes are of extraordinary size, and of a color varying from a dirty white to very pale yellow. The finer varieties of gambir vary in physical characteristics; sometimes it is in oblong instead of cubical pieces, without differing in other respects from the ordinary kind; sometimes in small circular cakes, or short cylindrical pieces, heavier than water, of a pale reddish-yellow color, moderately astringent, gritty under the teeth, and quite impure; sometimes in very small cubes, distinguishable by the black color they afford with tincture of iodine, indicating the admixture of sago or other amylaceous matter; and, finally, in circular cakes of the size of a small lozenge flat on one side and somewhat convex on the other, of a pale pinkish yellowish-white color, and a chalky feel. This is most highly esteemed by the natives in India. (*Pereira.*) At the Edinburgh Forestry Exhibition in 1885 the Maharajah of Johore exhibited specimens labelled "gambir produced in Johore." The first quality, which was "*makan*" (for eating), was in regular cubes, externally cassia-brown color, internally pale cinnamon brown, and yielded 32 per cent. of tannic acid; the second quality was in badly-formed cubes, externally brown and black, internally cinnamon, and yielded 30 per cent. of tannic acid; the third quality was in dull-brown, well-shaped cubes, internally pale brown, and yielded 19 per cent. of tannic acid. The oblong or *parallelopiped gambir* was of a uniform dull brown, very hard and strong, and yielded only 2 per cent. of tannic acid. Mr. MacEwan believes that the low percentage of tannin was due to the decoction not having been subjected to prolonged boiling, which favors the decomposition of catechin, with the formation of catechu-tannic acid. None of the finest varieties of gambir, such as are used by the natives for chewing, occur to any extent in American commerce. Prebble records his examination of a cube gambir of fine appearance which contained a large percentage of starch. (*P. J. Tr.*, 1893, 21.)

Enormous quantities of gambir are used both in Europe and America in tanning, calico-printing, and dyeing,

nally of a rusty brown more or less dark, internally varying from a pale reddish or yellowish brown to a dark liver color. In some specimens it is almost black, in others somewhat like the color of port wine, and in others again, though rarely, dull red like annatto. The extract has been distinguished into the *pale* and *dark* varieties; but there does not appear to be sufficient ground for retaining this distinction, at least in relation to the proper catechu obtained from the wood of *A. catechu*. Catechu is inodorous, with an astringent and bitter taste, followed by a sense of sweetness. It is brittle, and breaks with a fracture which is rough in some specimens, in others uniform, resinous, and shining. That which is preferred in our market is of a dark color, easily broken into small angular fragments, with a smooth glossy surface, bearing some resemblance to kino. Catechu is often mixed with sand, sticks, and other impurities. The U. S. P. gives the following tests of purity. "In irregular masses, containing fragments of leaves, dark brown, brittle, somewhat porous and glossy when freshly broken. It is nearly inodorous, and has a strongly astringent and sweetish taste. If a portion of Catechu be digested with 10 times its weight of alcohol, and the liquid filtered, the undissolved matter, after being dried at 100° C. (212° F.), should not exceed 15 per cent. of the original weight. The tincture, diluted with 100 parts of water, acquires a green color on the addition of ferric chloride test-solution. If two parts of Catechu be boiled with 20 parts of water, a brownish-red, turbid liquid will be obtained which turns blue litmus paper red. Upon incineration, Catechu should not leave more than 6 per cent. of ash." "Catechu should not afford any characteristic reaction with the tests for starch, and should not yield more than 5 per cent. of ash when incinerated." *Br.* The proportion of tannic acid, which may be considered the efficient principle, varies from about 45 to 55 per cent. in catechu or cutch, and from 36 to 40 per cent. in gambir. The portion designated by Davy as extractive is said to contain, if it does not chiefly consist of, a principle discovered by Buchner, and now called *catechin*, *catechuin*, or *catechuic acid*, to which Etti gives the formula $C_{18}H_{18}O_8$. To prepare pure catechin, Etti (*loc. cit.*) proceeds as follows. Catechu is dissolved in eight times its weight of boiling water, and the liquid, after being strained through a cloth, is left for some days until the insoluble catechin has subsided. The crude catechin is collected in a linen cloth and submitted to the action of a screw-press, then dissolved in a sufficient amount of dilute alcohol, and the filtered solution is shaken up with ether as long as any catechin is thereby dissolved; and after the ether has been removed by distillation the residue is taken up with distilled water, and the solution is left for a few days, when the catechin crystallizes out in an almost colorless state. After pressure in a cloth it is again dissolved in boiling water, when a yellowish-white body remains behind, which appears to be *quercetin*. The deep-red liquid remaining behind after the catechin has been dissolved out with ether contains *catechu red*, $C_{36}H_{34}O_{15}$, which is evidently the first anhydride of catechin. The *tannic acid* is of the variety which precipitates iron of a greenish-black color, and differs from most of the other varieties in not yielding grape-sugar when digested with dilute sulphuric acid. It is not, therefore, a glucoside. It precipitates gelatin, but not tartar emetic

and in other art processes requiring tannic acid. The finer grades are powerfully astringent, and may be used for the same medicinal purposes as the official catechu.

2. *Areca Catechu.* This is obtained from the *areca nut*, or *betel nut*, which is the seed of *Areca catechu*, a palm cultivated in all parts of India. (See PART II.) It is prepared by boiling the nuts in water and evaporating the decoction. There are two varieties: one of a black color, very astringent, mixed with paddy husks and other impurities, and obtained by evaporating the first decoction; the other, yellowish brown, of an earthy fracture, and pure, resulting from the evaporation of a decoction of the nuts which had been submitted to the previous boiling. The first is called *kassu*, the other *coury*. (Heyne, *Tracts, etc., on India.*) They are prepared in Mysore, and Ainslie states that both varieties are sold in the bazaars of Lower India, and used for the same purpose as the official catechu by the native and European practitioners. They are also much used for chewing by the natives. But they are seldom exported, and it is uncertain whether they find their way into European or American commerce. Pereira thought he had identified the *kassu* with a variety of catechu derived from Ceylon, where he had been informed that an extract of the areca nut is prepared. It was in circular flat cakes, from two to three inches in diameter, scarcely an inch thick, covered on one side with paddy husks, and internally blackish brown and shining, like Pegu catechu.

Guibourt and Pereira describe other varieties, which we have not met with, and which are probably rare. One of these is the *Siam catechu*, in conical masses shaped like a betel nut and weighing about a pound and a half. Its fracture is shining and liver-colored, like that of hepatic aloes; in other respects it resembles Pegu catechu. Another is the *black mucilaginous catechu* of Guibourt, in parallelopipeds an inch and a half in length by an inch in breadth. Internally it is black and shining, and its taste is mucilaginous and feebly astringent. A third is the *dull reddish catechu* of Guibourt, in somewhat flattened balls, weighing three or four ounces, of a dull reddish, wavy, and often marbled fracture. Many years since, an extract like this was brought to Philadelphia upon speculation by a merchant from Calcutta, but it is not now in the market. Lastly, there is a *pale* or *whitish* catechu, in small roundish or oval lumps, with an irregular surface, dark or blackish brown externally, very pale and dull internally, and of a bitter, astringent, and sweetish taste, with a smoky flavor. It is unknown in commerce.

(*Kane*), and is not, like the tannic acid of galls, converted into gallic acid by exposure to the air. It may be distinguished by the name of *catechu-tannic acid.* Catechu is almost wholly soluble in a large quantity of water, to which it imparts a brown color. The extractive or catechuic acid is much less soluble than the astringent principle, which may be almost entirely separated from it by the frequent application of small quantities of cold water. Boiling water dissolves it much more readily than cold, and deposits it of a reddish-brown color upon cooling. Both principles are readily dissolved by alcohol or proof spirit, and also by ether. For the important reactions of catechu, see *Acidum Tannicum.*

The importations of *cutch* or catechu and terra japonica or gambir for purposes of tanning and calico-printing are quite large, amounting in 1896 to 32,338,264 lbs., valued at $1,108.611, and in 1897 to 31,349,545 lbs., valued at $959,501. The total exports of gambir (common and cubes) from Singapore in 1897 amounted to 48,800 tons, of which 17,900 tons went to England, 17,500 tons to the United States, and 13,400 tons to the continent of Europe. M. de Meyer affirms that the best method of detecting adulteration of catechu is to treat the suspected drug with ether. Catechu of good quality, after repeated treatment with ether, loses 53 per cent. of its weight, and the dried residue weighs only 47 per cent. of the catechu employed. If this be exceeded, the drug must be proportionately impure. (*Journ. de Pharm.*, Juin, 1870, 479.) A. Jossart (*Journ. de Pharm. d'Anvers*, 1881, 41) examined a catechu which was adulterated with from 60 to 65 per cent. of ferrous carbonate. For methods of assaying catechu and gambir, see Trimble's *The Tannins*, 43; also *Pharm. Rev.*, 1897, 27.

Medical Properties and Uses. Catechu is a powerful astringent. The dark-colored is somewhat more powerful than the light, and is therefore usually preferred; but the light, being rather sweeter, is chosen by the Malays, Hindoos, and other East Indians, who consume vast quantities of this extract by chewing it, mixed with aromatics and a small proportion of lime, and wrapped in the leaf of the *Piper Betel.* Catechu may be advantageously used in most cases where astringents are indicated. The complaints to which it is best adapted are *diarrhœa* dependent on debility or relaxation of the intestinal mucous membrane, and *passive hemorrhages*, particularly from the uterus. A small piece held in the mouth and allowed slowly to dissolve is an excellent remedy in *relaxation of the uvula* and the *irritation of the fauces* and *troublesome cough* which depend upon it. Applied to *spongy gums*, in the state of powder, it sometimes proves useful; and it has been recommended as a dentifrice in combination with powdered charcoal, Peruvian bark, myrrh, etc. Sprinkled upon the surface of *indolent ulcers*, it is occasionally beneficial, and it is much used in India for the same purpose, in the form of an ointment. An infusion of catechu may be used as an injection in *obstinate gonorrhœa*, *gleet*, and *leucorrhœa*, and we have found it highly beneficial, when thrown up the nostrils, in arresting *epistaxis.* The dose is from ten grains to half a drachm (0·65–1·95 Gm.), which should be frequently repeated, and is best given with sugar, gum arabic, and water.*

CAULOPHYLLUM. U. S. Caulophyllum. [Blue Cohosh.]

(CÂU-LO-PHĬL'LUM.)

"The rhizome and roots of Caulophyllum thalictroides (Linné), Michaux (nat. ord. Berberidaceæ)." *U. S.*

Pappoose Root, Squaw Root, Blueberry Root.

Gen. Ch. Sepals 6, with three small bractlets at the base, ovate-oblong. *Petals* 6, thick and gland-like, somewhat kidney-shaped or hooded bodies, with short claws much smaller than the sepals, one at the base of each of them. *Stamens* 6; *anthers* oblong. *Pistil* gibbous, style short. *Stigma* minute and unilateral. *Ovary* bursting soon after flowering by the pressure of the two erect, enlarging seeds and withering away. The spherical *seeds* naked on their thick seed-stalks, looking like drupes; the fleshy integument turning blue; albumen of the texture of horn. (*Gray's Manual.*)

Caulophyllum thalictroides. Michaux.—*Leontice thalictroides.* Linn. This is an indigenous, perennial, herbaceous plant, with matted, knotty rhizomes, from which rises a single smooth stem, about two feet high, naked till near the summit, where it sends out a large triternately compound leaf, and ending in a small raceme or panicle of greenish-yellow flowers, at the base

* *Fluid Extract of Catechu.* Prof. Procter suggested the following formula for a *fluid extract of catechu* based on the solvent power of glycerin over this extract. *Eight troyounces* of pure catechu, in moderately coarse powder, are mixed in a mortar with *four fluidounces* of glycerin so as to form a paste, to which enough diluted alcohol is added to make a pint. The liquid is poured into a bottle, shaken occasionally for twenty-four hours, and then strained through muslin. Each fluidrachm represents thirty grains of catechu. (*Proc. A. P. A.*, 1863, p. 241.)

of which is often a smaller biternate leaf. The whole plant when young, as well as the seeds, which are about as large as peas, is glaucous. It is the only known species of the genus. It is found in most parts of the United States, growing in moist rich woods.

Properties. The root-stock is the only part used. It has a sweetish, pungent taste, and yields its virtues to water and alcohol. It is officially described as follows. "Rhizome of horizontal growth, about 10 Cm. long, and about 6 to 10 Mm. thick, bent; on the upper side with broad, concave stem-scars and short, knotty branches; externally grayish-brown, internally whitish, tough and woody. Roots numerous, matted, about 10 Cm. long, and 1 Mm. thick, rather tough; nearly inodorous; taste sweetish, slightly bitter and somewhat acrid." *U. S.* Mayer found caulophyllum to contain *saponin* and a colorless alkaloid (*A. J. P.*, 1863, 99), whilst A. E. Ebert subsequently obtained from it albumen, gum, starch, phosphoric acid, extractive, two resins, coloring matter, and a body analogous to saponin. The *caulophyllin* of the eclectics is made by pouring a concentrated alcoholic tincture into water and collecting, washing with ether, and drying the precipitate. Prof. J. U. Lloyd purified the substance which Ebert described as analogous to saponin, and for distinction terms it *leontin*. (See *Drugs and Medicines of North America*, vol. ii. 152.) He also obtained *caulophylline*, the alkaloid first announced by Mayer in 1863. Lloyd describes it as colorless, odorless, possessed of little taste, and dissolving freely in water, alcohol, ether, and chloroform. It crystallizes with difficulty. The hydrochlorate has been obtained, however, in crystals. It has not been tested physiologically. (*Proc. A. P. A.*, 1893, 115.)

Medical Properties. Caulophyllum has been scarcely used at all by the general medical profession, although the so-called eclectic or homœopathic practitioners claim for it peculiar valuable properties. It is said to be sedative, antispasmodic, and oxytocic, and to have the power when *uterine inertia* occurs during labor to cause the contractions to become very severe, without altering their general character as does ergot. It is also alleged to be capable of arresting threatened *abortion*, to be very efficacious in *hysteria*, *amenorrhœa*, *dysmenorrhœa*, *menorrhagia*, *uterine subinvolution*, etc.; also to be capable of originating uterine contractions and producing abortion. For a detailed description of the various more or less contradictory powers ascribed to it, the reader is referred to Lloyd's *Drugs and Medicines of North America*, vol. ii. p. 155. It is given in decoction, infusion, or tincture, the first two being made in the proportion of an ounce to a pint of water, the last of four ounces to a pint of spirit. Dose of decoction or infusion, one or two fluidounces (30 or 60 C.c.); of tincture, one or two fluidrachms. Leontin has been used in doses of one drachm of the one per cent. solution.

CERA ALBA. U. S., Br. White Wax.

(CĒ'RĄ ĂL'BĄ.)

"Yellow wax bleached." *U. S.* "Yellow Beeswax which has been bleached by exposure to moisture, air, and light." *Br.*

White Beeswax; Cire blanche, *Fr.;* Weisses Wachs, *G.;* Cera bianca, *It.;* Cera blanca, *Sp.*

CERA FLAVA. U. S., Br. Yellow Wax.

(CĒ'RĄ FLĀ'VĄ.)

"A peculiar, concrete substance, prepared by Apis mellifica, Linné (class, Insecta; order, Hymenoptera)." *U. S.* "Prepared from the honeycomb of the Hive Bee, Apis mellifica, Linn." *Br.*

Cera Citrina; Beeswax; Cire jaune, *Fr.;* Gelbes Wachs, *G.;* Cera gialla, *It.;* Cera amarilla, *Sp.*

Wax is a product of the common bee, *Apis mellifica* of naturalists, which constructs with it the cells of the comb in which the honey and larvæ are deposited. It was at one time doubted whether the insect elaborated the wax by its own organs, or merely gathered it from vegetables. The question was set at rest by Huber, who fed a swarm of bees exclusively on honey and water, and found that they formed a comb consisting of wax. This, therefore, is a proper secretion of the insect. It is produced in the form of scales under the rings of the belly. But wax also exists in plants, bearing in this, as in other respects, a close analogy to the fixed oils. It is, however, the product of the bee only that is recognized by the Pharmacopœias.* This is

* *China wax*, called *pe-la* by the Chinese, resembles spermaceti in whiteness and crystalline appearance, but is distinguished by greater hardness and friability and a somewhat fibrous fracture. It melts at about 83° C. (181° F.), is very slightly soluble in alcohol or ether, is insoluble in cold oil of turpentine and rectified petroleum, but is dissolved with the aid of heat, and very soluble in benzol. These solubilities distinguish it from spermaceti. (*P. J. Tr.*, xiv. 9.) It was formerly supposed to be of vegetable origin, but has been ascertained to be the product of an insect

directed in two forms: 1, that of *yellow wax*, procured immediately from the comb; and, 2, that of *white wax*, prepared by bleaching the former. We shall consider these separately, and afterwards give an account of *vegetable wax*.

1. CERA FLAVA, or *Yellow Wax*. This is obtained by slicing the comb taken from the hive, draining and afterwards expressing the honey, and melting the residue in boiling water, which is kept hot for some time in order to allow the impurities to separate and either subside or be dissolved by the water. When the liquid cools the wax concretes, and, having been removed and again melted in boiling water, is strained and poured into pans or other suitable vessels. The labor-saving device is sometimes adopted of stretching a strainer of cheese-cloth upon a hoop and wedging the latter down into the hot mixture below the level of the water; as this cools, the melted wax slowly rises through the cloth, and thus a perfectly clean cake of wax is formed on top on cooling. It is usually brought to market in round flat cakes of considerable thickness. The druggists of Philadelphia are supplied chiefly from the Western States and North Carolina, especially the latter, and from Cuba and California.

Properties. Yellow wax is "a yellowish to brownish-yellow solid, having an agreeable, honey-like odor, and a faint, balsamic taste. Specific gravity, 0·955–0·967 at 15° C. (59° F.).* Melting point, 63°–64° C. (145·4°–147·2° F.). It is brittle when cold, and when broken presents a dull, granular, not crystalline fracture. By the heat of the hand it becomes plastic. Yellow Wax is insoluble in water, sparingly soluble in cold alcohol, but almost completely in boiling alcohol. It is completely soluble in ether, chloroform, and in fixed and volatile oils; partially soluble in cold benzol or carbon disulphide, and completely in these liquids at a temperature of 25° to 30° C. (77° to 86° F.). If 1 Gm. of Yellow Wax be boiled, for half an hour, with 35 C.c. of a 15-per-cent. aqueous solution of sodium hydrate, the volume being preserved by the occasional addition of water, the Wax should separate, on cooling, without rendering the liquid opaque, and no precipate should be produced in the filtered liquid by hydrochloric acid (absence of *fats* or *fatty acids*, *Japan wax*, *resin*); nor should the same reagent produce a precipitate in water which has been boiled with a portion of the Wax (absence of *soap*). If 5 Gm. of Yellow Wax be heated in a flask, for fifteen minutes, with 25 C.c. of sulphuric acid, to 160° C. (320° F.), and the mixture then diluted with water, no solid, wax-like body should separate (absence of *paraffin*). If a portion of Yellow Wax be ignited on platinum, it should not emit the odor of acrolein (absence of *tallow* and *other fats*)." *U. S.* The British Pharm. states that yellow wax should be "Firm, breaking with a granular fracture, yellowish, having an agreeable honey-like odor. Not unctuous to the touch. It should be readily and entirely soluble in hot *oil of turpentine*. It should not yield more than 3 per cent. to cold *alcohol* (90

belonging to the genus Coccus, which fixes itself to the branches of a certain tree, and, investing them closely, becomes embedded in a waxy material, which is scraped off with the insects, and constitutes the crude wax. It is purified by melting and straining. (Hanbury, *P. J. Tr.*, xii. 476.) The tree from which the wax is obtained is the *Fraxinus chinensis* of Roxburgh. (*Ibid.*, Sept. 1, 1859.)

Mr. T. T. Cooper, in his "Travels of a Pioneer" in China, gives some interesting statements as to the production of this wax, which are the result of his own personal observations. It is chiefly the province of S'zchuan which is the seat of this industry, the cultivation of the China wax being a source of great wealth to this province, second only in importance to the silk-culture. The "wax trees" are all cut down at the height of 8 feet, leaving no branches, the trunks being about as thick as a man's thigh, and sending forth shoots in the spring. The insects are cultivated in a different province, that of Yunnan, whence vast quantities of the eggs are sent annually to S'zchuan, where they are received in little balls of the size of a pea. These are suspended, enclosed in young leaves, to the shoots of the tree in March. In about two months the larvæ appear, and, feeding on the leaves, soon attain the size of small butterflies, which spread themselves in immense numbers over the branches, which are whitened by them so as to seem covered with feathery snow. The grub, as it advances to the chrysalis form, buries itself in a white secretion by which all the branches are coated an inch in thickness. These are then cut off near the stem and divided into small pieces, which are tied in bundles and put into large caldrons, where they are boiled in water till all the wax melts and rises to the surface. It is then skimmed off and run into moulds, where it hardens. In this form it is spread over the Empire, where it is used for candles and as medicine. (*P. J. Tr.*, 1872; also vol. xv., 1885.)

* The lower official specific gravity (0·955) is undoubtedly too low; it should be 0·960. Dieterich has modified Hager's method of taking the specific gravity of wax, as follows. A piece of wax is heated on the edge of a colorless flame, so that drops of melted wax may fall into alcohol placed in a saucer. Having thus obtained about a dozen wax-pearls, they are allowed to dry thoroughly by letting them remain on blotting-paper for 24 hours. Eight portions of diluted alcohol are prepared, of the following specific gravities respectively: 0·960, 0·961, 0·962, 0·963, 0·964, 0·965, 0·966, 0·967, and the pearl is dropped into these liquids in turn. The specific gravity of the wax is of course the same as the specific gravity of that liquid in which the pearl remains floating indifferently in any part of the vessel. (See Remington's *Practice of Pharmacy*, page 71, *Lovi's beads*.) Dieterich examined hundreds of specimens annually, and found the wax to vary in sp. gr. from 0·963 to 0·966. He also determined the specific gravities of the following substances used to adulterate wax: white wax, 0·973; cera japonica, Japan wax, 0·975; ceresin, half white, 0·920; ozokerite, crude, 0·952; rosin, common, 1·108; cacao butter, 0·980–0·981; pure rosin, 1·045; beef suet, 0·952–0·953; yellow wax, 0·963–0·964; ceresin, white, 0·918; ceresin, yellow, 0·922; spermaceti, 0·960; French rosin, 1·104–1·105; paraffin, med. hard, 0·913–0·914; stearin, A No. 1, 0·971–0·972; mutton suet, 0·961. (*Arch. d. Pharm.*, 1882, p. 55.)

per cent.), nor more than 50 per cent. to cold *ether*, and nothing to *water* or to boiling *solution of sodium hydroxide*, the two latter liquids after filtration neither being turbid nor yielding a precipitate on the addition of *hydrochloric acid* (absence of fatty acids, resin, and Japan wax). Specific gravity 0·960 to 0·970. Melts at 144·5° to 147° F. (62·5° to 63·9° C.) when tested in the following manner. Liquefy a small piece, and draw a little of the liquid Beeswax up into a capillary tube of not more than one millimetre in internal diameter; after it has been allowed to cool for three hours, fix a piece of the filled capillary tube to the bulb of a thermometer by thread; immerse the bulb and tube in a beaker of water, and heat the latter gradually on a water-bath; at the moment the opaque rod of Beeswax becomes transparent, note the temperature. The solidifying point is two to three degrees lower than the melting point. 5 grammes of the Beeswax, melted in and mixed with boiling *alcohol* (90 per cent.), should require for neutralization not less than 1·6 cubic centimetres of *normal alcoholic volumetric solution of potassium hydroxide*, using *phenol-phthalein* as an indicator. Upon the further addition of 20 cubic centimetres of the volumetric solution, and well boiling for one hour under a reflux condenser, not less than 6·2 nor more than 6·8 cubic centimetres should be found to have combined with the Beeswax, as shown by the titration of the uncombined alkali with *volumetric solution of sulphuric acid*. If 5 grammes of Beeswax are heated for fifteen minutes with 25 grammes of *sulphuric acid* to 320° F. (160° C.) and the mixture diluted with *water*, no solid wax-like body should separate (absence of paraffin). Beeswax should not yield any characteristic reaction with the tests for starch."

Various adulterations have been practised, most of which may be readily detected. Meal, earth, and other insoluble substances are at the same time discovered and separated by melting and straining the wax. When the fracture is smooth and shining instead of being granular, the presence of resin may be suspected. This is dissolved by cold alcohol, while the wax is left untouched. Yellow wax is frequently adulterated with a mixture of paraffin and rosin; such wax is usually translucent on the edges. For other adulterating substances used, and the modes of detecting them, see the remarks which follow on white wax.

Yellow wax is used chiefly as an ingredient of plasters and cerates.

2. Cera Alba, *Bleached Yellow Wax*, or *White Wax*. The color of yellow wax is discharged by exposing it, with an extended surface, to the combined influence of air, light, and moisture. The process of bleaching is carried on to a considerable extent in this country. The wax, previously melted, is made to fall in streams upon a revolving cylinder, kept constantly wet, upon which it concretes, forming thin ribbon-like layers. These, having been removed, are spread upon linen cloths stretched on frames and exposed to the air and light, care being taken to water and occasionally turn them. In a few days they are partially bleached; but, to deprive the wax completely of color, it is necessary to repeat the whole process once, if not oftener. When sufficiently white, it is melted and cast into small circular cakes. The color may also be discharged by chlorine; but the wax is said to be somewhat altered.* White wax sometimes contains one or more free fatty acids, consequent probably upon the employment of alkalies in bleaching it, which render it an unfit ingredient in the unctuous preparations of certain salts. Of these acids it may be deprived by means of alcohol.

Perfectly pure wax is white, shining, diaphanous in thin layers, inodorous, insipid, harder and less unctuous to the touch than the yellow, soft and ductile at 35° C. (95° F.) and fusible at 65° C. (149° F.), retaining its fluidity at a lower temperature. According to Saussure, its sp. gr. in the solid state is 0·966. The U. S. Pharmacopœia describes it as "a yellowish-white solid, somewhat translucent in thin layers, having a slightly rancid odor, and an insipid taste. Specific gravity, 0·965 to 0·975† at 15° C. (59° F.). Melting point, about 65° C. (149° F.). In other respects White Wax has the characteristics of, and should respond to the reactions and tests given under, Yellow Wax (see *Cera Flava*)." By a great heat it is partly volatilized, partly decomposed; and, when flame is applied to its vapor, it takes fire and burns with a clear bright light. It is insoluble in water, and in cold alcohol or ether, but is slightly

* The following process for purifying wax by steam has been patented by M. Cassgrand, in France, and is said to have been employed advantageously. Wax melted by steam is passed along with the steam through a coiled tube or worm, is received into a double bottom heated by steam, where it is washed with water, and is then raised by a pump into another pan, also heated by steam, where it is again washed with water; the whole operation is repeated three or four times, the wax being allowed to rest for about four or five minutes in the upper pan after each operation, and, after the last one, an hour or two for the subsidence of impurities. The wax is then granulated by means of cold water, allowed to dry for two or three days, and then exposed to light and air. The whole process is completed in a few days. (See *A. J. P.*, xxvi. 525.)

† This official specific gravity (0·975) is undoubtedly too high. 0·960 to 0·965 should be the figures.

soluble in boiling alcohol and ether, which deposit it in a great measure upon cooling. The volatile and fixed oils dissolve it with facility, resin readily unites with it by fusion, and soaps are formed by the action of soda and potassa in solution. It is not affected by the acids at ordinary temperatures, but is converted into a black mass when boiled with concentrated sulphuric acid. Bleached wax contains, according to Lewy's analysis, 80·2 per cent. of carbon, 13·4 of hydrogen, and 6·4 of oxygen. It is a mixture of three different substances, which may be separated from one another by alcohol,—viz.: 1, *myricin*, insoluble in boiling alcohol, and consisting chiefly of myricyl palmitate, $C_{16}H_{31}(C_{30}H_{61}O_2)$,—that is, a compound of *palmitic acid*, $C_{16}H_{31}O.OH$, and *myricyl alcohol*, $C_{30}H_{61}OH$; 2, *cerotic acid*, $C_{27}H_{54}O_2$ (formerly called *cerin* when obtained only in an impure state), which is dissolved by boiling alcohol, but crystallizes out on cooling; 3, *cerolein*, which remains dissolved in the cold alcoholic liquid. This latter is probably a mixture of fatty acids, as indicated by its acid reaction. Schwalb (*Ann. d. Chem.*, 224, 225) found melissic acid and some unsaturated acids of the oleic series; also higher solid hydrocarbons of the saturated series, such as $C_{27}H_{56}$ and $C_{31}H_{64}$. Kebler states that the hydrocarbons in beeswax amount to from 12·72 to 13·78 per cent. (*A. J. P.*, 1893, 587.) T. Marie believes that cerotic acid, as ordinarily obtained, is a mixture of two distinct acids. He gives $C_{30}H_{60}O_2$ as the formula for melissic acid and $C_{25}H_{50}O_2$ for pure cerotic acid.
